It may be necessary to treat for shock, as indicated by the color of the face and a general depression or stupor of the injured person, approaching semi-unconsciousness. Hot coffee or hot tea should be given in small quantities at a time, or a half-tablespoonful of aromatic spirits of ammonia in a tablespoonful of water. If whiskey or brandy is the only stimulant available give but one large drink or swallow, as more may cause further depression. Smelling salts held to the nose is good. Avoid exposing the person to a cold current of air and protect him by a covering of coats or blankets to overcome the effects of shock when this is apparent from observation of the victim.

FOREIGN MARKETS AND EXPORT NEWS

EDITED BY ALEX MOSS

Opportunities in Foreign Markets for American Coal

ALGERIA

[Consul A. C. Frost, Algiers, Jan. 29, 1919]

Algeria is greatly in need of coal at the present time. The gas works have been practically closed for the past year and other public utilities greatly embarrassed for lack of coal. According to the statement of a local official, Algeria requires annually for its railways 180,000 tons; the gas and electric establishments, 95,000 tons; industries and agriculture, 125,000 tons; a total of 400,000 tons. In 1913 Algeria imported 2,251,000 tons of coal, including bunker coal. Imports have progressively declined since the war, on account of lack of means of transportation, and in 1917 they amounted to only 228,000 tons.

Before the war American coal could not compete to advantage with British coal, on account of the higher transportation charges; but it is thought that conditions may be more advantageous in this respect after the war.

[A list of three persons or firms in Algiers who have expressed a desire to represent American coal companies can be obtained from the Bureau of Foreign and Domestic Commerce or its district or coöperating offices by referring to file No. 114099.]

BRITISH GUIANA

[Consul G. E. Chamberlin, Georgetown, Jan. 27, 1919]

The annual importation of coal into British Guiana is from 27,000 to 35,000 tons, all soft or steam coal. This is used chiefly for bunkering, although the sugar estates and the Demerara Electric Co., Ltd. (electric lighting and tramways), use some imported coal. The price of coal imported the last of January was $20.10 c. i. f. Georgetown—the importers paying tonnage and light dues of 25 and 4 cents, respectively, per ton for cargo landed; pilotage, which for a vessel drawing from 17 to 18 ft. is $25; and landing charges from vessel to wharf, 32 cents. In case the coal is discharged into lighters the charge for lighterage is 72 cents per ton.

During the past three years most of the coal consumed in the colony has been imported from the United States; prior to that, chiefly from the United Kingdom. During the high price of coal considerable wood fuel has been used by the local steamer services, the Demerara Electric Co. (Ltd.), the sugar estates, and the Demerara Railway Co. The latter in normal times uses patent fuel exclusively, and probably will return to that when obtainable.

There are no gas plants in this consular district. The municipal waterworks of Georgetown and the municipal electric lighting plant at New Amsterdam use wood fuel almost exclusively.

[A list of the leading importers of coal in Georgetown, British Guiana, can be obtained from the Bureau of Foreign and Domestic Commerce or its district or coöperating offices by referring to file No. 110980.]

FRANCE

[Consul General George A. Bucklin, Bordeaux]

The coal question in France is a complicated one, and will be so for several years to come. Before the war practically all of the coal consumed in this region came from England and Germany, only an insignificant amount being mined here. Now coal is an urgent need, and will continue so to be. England has not enough to supply the demands made upon it, and it is the endeavor, of course, to totally eliminate German coal importation. America will have to supply its share of the demand.

At present the purchase and distribution of coal is made by the French government, but, it is understood, this will not continue for longer than about April, 1919, and when the coal traffic goes back into the hands of the merchants American coal will undoubtedly be sought.

Under normal conditions American coal finds competition difficult with other foreign coal having much shorter hauls. But it is affirmed that the French government, through some sort of agency, will exert control over the price of coal to the effect that an average sale price will be set and the cost and profits will be pooled and divided among all the coal merchants in France, according to the tonnage sold by each. The individual merchant will, of necessity, pay the price required by his foreign exporter; but the cost to him and the selling price to his clients will be arranged by this clearance agency so that an average profit per ton sold will be allowed to each merchant, and the selling price of coal will be the same all over France. This arrangement is to hold good for one or more years, in accordance with the needs and its usefulness.

[A list of large coal dealers and importers in Bordeaux, France, can be obtained from the Bureau of Foreign and Domestic Commerce or its district or coöperating offices by referring to file No. 110591.]

The consumption of coal in Marseille, prior to the war, states Consul General A. Gaulin, Marseille, under date of Feb. 5, 1919, averaged about 2,500,000 tons, of which about 1,500,000 tons were imported—chiefly from the United Kingdom. From 40 to 45 per cent. of the imports consisted of bunker coal. There were only occasional imports of American coal, and these depended largely upon the labor situation in Wales, and the available supplies of British coal. During the last few years, owing to the war conditions, the imports have fallen off considerably. But a revival of this trade is imperative and inevitable, and there is an excellent opportunity for American coal exporters to secure a permanent foothold in this market. It is estimated that the local requirements during the next few years will be approximately 3,000,000 tons annually.

Steam and locomotive coals are and will remain in great demand. At least 50,000 tons of gas coal and 100,000 tons of anthracite will also be required. The American coals best known at Marseille are Pocahontas and New River. It is reported that the freight rates from Wales to Marseille have been recently fixed at 42s. ($10.22) per long ton. But large shipments from England are unlikely in the near future.

[A list of dealers in and importers of coal at Marseille, France, may be obtained from the Bureau of Foreign and Domestic Commerce or its district or coöperative offices by referring to file No. 113899.]

SPAIN

[Consul Louis G. Dreyfus, Jr., Malaga, Feb. 5, 1919]

There is an excellent market for American coal in Malaga. During the past year the small quantity which was imported was from England for the Altos Hornos, the local steel mill, for use in the completion of orders for the allied governments. The rest that was used in Malaga was received

Coal and Coke Exports from New York in March

The lack of shipping, together with the high cost of freight, accounts, at least in part, for the decrease in the tonnage of anthracite and bituminous coal and coke sent to foreign countries from the Port of New York during March of this year. Comparing these figures with those of March in 1917 and 1918, shows a considerable loss in tonnage but a decided increase in the value of the exports, excepting that of coke.

Reference to the list of countries to which fuel was sent last March shows an almost complete change in markets from the countries to which shipments were made in March, 1917, much of which can be attributed to the war.

The following tabulation shows the tonnage of coal and coke shipped from the Port of New York to foreign countries during March in 1917, 1918 and 1919, together with the total value and the average cost per ton, thereof:

	Anthracite						Bituminous						Coke					
	1917		1918		1919		1917		1918		1919		1917		1918		1919

Salvador															5	190		
Trinidad							30	176										
Venezuela	205	2,306					60	275			6	125	40	480				
Totals	13,720	$105,657	2,607	$20,050	904	$9,350	3,224	$19,649	4,508	$27,190	140	$1,732	505	$6,273	956	$14,481	390	$5,582
Average cost per ton		$7.70+		$7.69+		$10.34+		$6.09+		$6.03+		$12.37+		$12.42+		$15.18+		$14.31+

from the Spanish mines at Penarroya, Puerto-Llano and Asturias. As soon as trade conditions are normal again, however, the national product will not be able to compete with foreign coal, not only because of its very inferior quality, but also because of the increased railway-freight rates from the mines to Malaga. As it is, wood and "orujo" (the residue of the olives after extraction of oil) have been substituted for coal wherever possible.

The estimated annual consumption of coal in Malaga is 100,000 tons. On account of the mild climate other fuels are used in heating and cooking. With the exception of a part of the coal used by the Andaluces Ry., which has a very favorable contract with the Penarroya Coal Co., most of the supply used locally has been imported in the past from Cardiff and Newcastle. It is probable that English coal will continue to supply the market unless American exporters can sell their product laid down at Malaga at the same or better figures. This will largely depend upon freights.

The present is a very advantageous time for American coal to enter this market. Vessels would not have to return in ballast, but could, in season, obtain cargoes of olive oil, oxide of iron, almonds, essential oils, etc. The import duty on coal is 3.50 pesetas ($0.67) per metric ton.

[A list of coal dealers and large consumers in Malaga, Spain, may be obtained from the Bureau of Foreign and Domestic Commerce or its district or coöperating offices by referring to file No. 113814.]

SWITZERLAND

[Consul H. H. Dick, Basel, Feb. 27, 1919]

The prospects for the importation of American coal into Switzerland seem very good, providing the necessary colliers can be obtained to transport it. In normal times about 250,000 tons of coal are needed each month for all purposes in Switzerland. Practically all of this coal was formerly imported from Germany, although small quantities came from Austria, France and England. That from England was employed principally, under control of the British Board of Trade, by industries manufacturing products for Great Britain.

Coal is absolutely necessary for Swiss industry. Without it industry must cease. Because of its shortage the Swiss railway officials have been forced five times to curtail traffic on the Federal railways, even eliminating all trains on Sundays and all express trains. Germany took advantage of Switzerland's situation and raised the prices gradually until June, 1918, when by a convention Switzerland was forced to pay double the former prices in Swiss francs instead of in marks, which had fallen in value. The prices per carload (10 tons) established in June, 1918, for coal at the mine were as follows: Bituminous from the Saar, 1900 francs ($366.70); briquets or anthracite from the Ruhr, 2000 francs ($386). In carload lots (10 tons each) the freight costs were as follows: Rail transportation from Saar to Basel, 115 francs ($22.20); from Ruhr to Basel, 210 francs ($40.53); rail and water transportation from Ruhr to Basel, 260 francs ($50.18).

The retail prices based on these costs were: Bituminous from the Saar, 250 francs ($48.25) per metric ton; coke (made at Basel), 300 francs ($57.90) per metric ton; anthracite (assorted domestic), 270 francs ($52.11) per metric ton.

Now that Germany is no longer in a position to force Switzerland to pay such prices, the effort is being made to arrange for delivery at greatly reduced rates, and thus convert into cash enormous stocks accumulated at the mines of the Ruhr. It will be difficult, however, for Germany to make delivery owing to a scarcity of rolling stock, as well as to existing internal disorders. Belgium has recently offered 600,000 tons of coal to Switzerland, and the importations from France and England are increasing. It is thought by various dealers that the prices for both German and Entente coal will fall to about 120 francs ($23.16) per metric ton delivered at the Swiss frontier.

Dealers will be glad to receive offers for American coal, quoting prices c. i. f. Cette, France or Rotterdam. The latter place is preferred, as coal can be transported either by rail or water directly to Basel.

[A list of coal dealers in Basel, Switzerland, can be obtained from the Bureau of Foreign and Domestic Commerce or its district or coöperating offices by referring to file No. 113690.]

An arrangement has been arrived at between Poland and German-Austria to prolong the agreement whereby Austria is supplied with coal from Poland. The tonnage thus supplied is still very small owing to the Dombrowa mines in Poland not having yet got into working order.

Foreign Coal Trade Opportunity

The municipal authorities of a city in Austria who are in charge of the electric center, waterworks and tramway service desire to purchase coal, reports an American consular officer. Correspondence may be in English. Those interested may obtain further information by writing to the Bureau of Foreign and Domestic Commerce, Washington, D. C., or any of its branches and referring to file No. 29195.

New Coal Rates to Europe

Announcement was recently made by the Shipping Board of new rates on coal from North Atlantic ports to various European ports of destination. The new and reduced rates range from $22.50 a ton of 2240 lb. to $31 a ton, with a guaranteed daily discharge of from 700 to 1500 tons.

The new rates as announced by the board were as follows:

	Coal per Ton of 2240 Lb.	Guaranteed Daily Discharge Tons
Bordeaux-Havre	$22.50	700
Antwerp-Rotterdam	22.50	1000
Gothenburg (Sweden)	26.50	1000
Copenhagen-Ronne (Denmark)	27.00	1000
L'dskrona-Malmo (Sweden)	27.00	1000
Oxleosund (Sweden)	28.00	1000
Stockholm	28.00	1500
Marseilles	26.00	1000
Genoa	26.50	1000
Naples	26.00	1000
Trieste-Fiume-Venice	31.00	800

Discharge as above indicated, with time counting 24 hours after arrival of vessel, whether in berth or not, Sundays and holidays only excepted. If discharge is not completed within the time specified demurrage to be paid at the rate of $1 per net registered ton per running day, payable day by day.

These rates are not applicable on bookings made prior to announcement.

Homeward rates from above ports to United States ports, or commodity rates for homeward cargo will be established and quoted upon application.

Coal Resources of Netherlands

Under date of Feb. 11, Minister John W. Garrett reports from The Hague that with a prolonged spell of cold weather the coal problem has again assumed a leading position in the Netherlands, and the question of that country's independence of foreign powers for its fuel supply is once more being actively debated. A few weeks ago an official report was issued estimating the coal resources of the country as 1,766,000,000 tons in the Peel district, 3,165,903,537 tons in southern Limburg, and 324,000,000 tons in the Winterwijkschegebied. This makes a grand total of 5,255,803,537 tons of coal, sufficient to supply the Netherlands, at the pre-war rate of consumption of 10,000,000 tons per annum, for 525 years. None of this, however, is first-grade coal.

In addition to the question of availability of coal, the question of cost renders it of vital interest for Holland to achieve a position of independence in this regard. Last year the price of coal in Limburg amounted to 17 florins (the normal exchange value of the florin is 40.2 cents) per ton, whereas Germany demanded 90 florins per ton. This year Germany has reduced the price to 50 florins; but, in view of the scarcity of coal throughout Europe as a result of greater demand and destroyed mines, no appreciable decrease in the price of foreign coal is expected at present.

Will Ship Coal to Sweden

Coal will be shipped to Sweden by the Hutchinson Coal Co. operating in the Fairmont region of West Virginia, that company having recently secured a contract calling for the delivery of 10,000 tons to that country, the contract specifying that only lump coal shall be shipped. Heretofore little or no coal has been exported to Sweden, and the order placed with the Hutchinson company is regarded as beginning of an extensive coal trade with that nation. The order in question has furnished work for the miners at the Laura Lee, Mt. Clare and Erie mines of the company.

Australia in Need of Coal

Advices from Melbourne under date of Apr. 21 state that owing to the quarantine due to the epidemic of influenza a serious coal shortage has resulted in Australia. On the date given there was only three weeks' supply of fuel on hand and many industries were threatened by a forced shutdown.

London Secretary of American Chamber of Commerce

George P. Toby, long connected with banking and industrial corporations in this country, has been appointed Executive Secretary of the American Chamber of Commerce in London and will sail for his new post about May 12, meanwhile conferring with American merchants as to the service which the American Chamber in London can render them. Mr. Toby has been long known as an investment banker, and in this capacity has made a careful study of the operation of American industrial and public utility corporations.

G. M. Cassatt, president of the American Chamber of Commerce in London, who is now in the United States, in announcing the appointment explained that the London organization has as its members the representatives in England of American manufacturing and exporting interests, and also of the foremost British manufacturers and exporters, too, and importers from the United States. The former are active members, the latter associate. The Chamber has standing committees on finance, commerce and trade, transportation, trade information, etc., and the membership is also divided by businesses into trade groups, each working through its own committee. Thus almost any inquiry can be expeditiously handled by referring it to the proper committee or proper trade group.

"The London Chamber," Mr. Cassatt concluded, "wants to be used. What we most desire is that the individual American manufacturer, merchant, exporter from one end of the country to the other should learn to look upon us as an overseas service bureau of his own—on the spot and on the job, ready to work for him, to protect his hand and to look out for his interests. We are there to promote American business."

COAL AND COKE NEWS

EDITED BY ALEX MOSS

Harrisburg, Penn.

Representative Donnelly of Schuylkill County has introduced in the House a bill (1320) requiring the delivery of explosives to miners in the anthracite region at points below the surface. The bill provides that on and after July 1, 1919, explosives to be used by the miners in the hard-coal fields shall be delivered to them by the operator at a point below the surface most convenient to their place of work. The quantity supplied to each miner shall be in accordance with an order left by such miner at the mine foreman's office the day previous, and the quantity not to exceed the amount provided by law. The bill also provides that any operator who fails or neglects to furnish explosives to the miners as provided in the act shall be liable to a fine of ten dollars for each failure.

A bill to regulate the weight of anthracite coal and imposing penalties for short weight has been introduced by Representative Norton. This bill states that on and after the first day of July, 1919, two thousand pounds shall make or constitute a legal ton of coal throughout the state. A fine of $50 is to be made in all cases of short weight, provided that in all cases thirty pounds shall be allowed for the variation in scales.

A measure granting the right to corporations to construct and operate tunnels under the bed of navigable streams, where necessary to reach their coal supply, subject to the approval of the Water Supply Commission, was presented by Senator Crow of Fayette County, on Apr. 30.

A bill was presented to the House on Apr. 30 by Mr. Phillips, of Clearfield, providing that bituminous miners may collect at law rates due for mining coal, 76 lb. to constitute a bushel and 2000 lb. a ton. All mine cars are required to be uniform in capacity.

Five years without a single fatality in the mine under his care, is the record made by Harry Lewis, foreman of the Primrose colliery of the Lehigh Valley Coal Co., near Mahanoy City, and his work has been formally recognized by P. C. Fenton, State Mine Inspector in the Twentieth Anthracite District, who has written a letter of congratulation to Mr. Lewis.

Actual fatalities in the anthracite mines have decreased from 618 in 1913, to 551 in 1918, while the deaths per million tons of output have shrunk from 6.75 in 1913 to 5.54 in 1918. It has been the intelligent application of good mining principles and "safety first" ideas by the operating companies, through foremen like Mr. Lewis, which has helped to lessen the hazards of mining.

Mr. Lewis has been with the Lehigh Valley Coal Co. ever since 1897, when he was appointed fireboss at Packer No. 5. In 1904 he was made assistant foreman, and in 1910 he was made foreman at the Primrose colliery, which position he still holds.

Charleston, W. Va.

Both operators and miners in West Virginia are up in arms over the developments of the last week or two in connection with railroad fuel purchases, the publication of figures showing that some operators in the state sold coal for April delivery for as low as $1.60 per ton. The miners have denounced such sales in unmeasured terms and see in such a policy an effort to reduce wages, while operators are chagrined at the supine way in which some of the men in their industry have fallen in with the plans to beat down coal prices.

A large tonnage of coal was sold to the railroads at prices ranging from $1.60 to $1.85—a price considerably below the price fixed by the Government. Coal men who realize the organized effort being made to "bear" the coal market deplore the lack of organization and cohesion among those in the industry.

Aside from developments as to railroad fuel prices, the outlook for the industry in the state at the end of April was somewhat more encouraging. Certainly production had reached a somewhat higher level in many of the West Virginia fields, the improvement in a single week being pronounced.

It was estimated that in several districts the output had reached about 50 per cent of the full-time capacity. Larger quantities of coal were being moved both to the West and to tidewater, lake business having augmented the demand in West Virginia, production in several districts having been considerably increased as a result of a growing demand from lake territory. Even slack felt the effect of the growing demand, byproduct companies appearing to be in the market for larger quantities of this coal. Coke production, however, is still lagging.

Fairmont, W. Va.

A perfect furor was created in the Northern West Virginia fields during the fourth week of April when it became known that eight or ten different companies had been selling railroad fuel during April for a price as low as $1.60 a ton and from that up to $1.85. Prices at which 61,000 tons of coal were sold by these operators to the New York, New Haven & Hartford Railroad Co. during April are as follows. A. McBeil & Sons, 8000 tons at $1.85; George E. Warren Co., 10,000 tons at $1.75; Antler Coal Co., 5000 tons at $1.75; Har Mar Coal Co., 5000 tons at $1.75; Knickerbocker Fuel Co., 10,000 tons at $1.60; West Virginia and Pennsylvania Coal Co., 10,000 tons at $1.85; Knickerbocker Fuel Co., 10,000 tons at $5.74, that price being for coal delivered alongside Port Liberty piers, trimmed and bunkered. The fact that coal companies would become a party to the effort of the Railroad Administration to break down coal prices could hardly be credited.

There was a nearer approach to normal, however, in coal loadings during the week ending Apr. 26 than during previous weeks, coal men declaring that production was approaching 75 per cent., basing their estimate on the fact that the average loadings were 600 cars a day. It is even predicted that within 30 days shipments will have reached normal levels, though all do not concur in such a prediction, being rather inclined to believe that not before the end of the summer will there be full-time production.

The number of idle mines is still quite large, but it is apparent that a larger tonnage is being mined where mines are running. Increased fuel orders and increased lake orders have contributed to the increase in the total shipments from Northern West Virginia. Coal is moving to lake points at about the rate of 300 cars a week.

Dallas, Tex.

Slackness in the coal-mining operations in Texas, Oklahoma and Arkansas at this time is bringing the people of these states and other states that look to them for their fuel supply, dangerously near the famine point, according to coal dealers here. Coal-mining operations have been slack throughout the season. Various causes have contributed to this. First, there has been a marked shortage of railroad rolling stock, which has made the transportation of coal next to impossible. This has been reflected in decreased operations at the mines. Second, there have been various labor disputes which have tied up various mines for considerable lengths of time, and there has been a dearth of miners in some localities, especially in Texas, where the miners found work in the newly developed oil fields more profitable.

Last year the domestic consumers were induced to purchase their winter supply of coal early, and thus the mines were kept in operation throughout the summer months. But this year the consumers have not so purchased their coal. Dealers say there will be a greater shortage of coal in the Southwest next winter than last year, unless the consumers are induced to purchase their coal supply during the summer months and the mines can be kept in operation.

According to some coal operators, the production of coal in the Southwestern district must be increased at least one hundredfold if the threatened famine is to be avoided. These operators say the mine operations have so slackened that there is hardly any coal reserve on hand.

Boise, Idaho

With the signing by Governor Davis of House Bill No. 40, there has been created in Idaho a Bureau of Mines and Geology which, if properly directed, should in time become an important factor in the development of the mineral resources of the state. The board of control of this bureau is composed of Governor D. W. Davis, as chairman; the president of the Idaho Mining Association; Jerome J. Day, of Moscow; the professor of geology at the University of Idaho; D. C. Livingston, the state mine inspector; Robert N. Bell, and the dean of the School of Mines; Francis A. Thompson, as executive secretary.

The initial appropriation is $30,000 for the biennium, the general distribution of which is provided for by the act as follows: "For coöperation work with the United States Bureau of Mines, $15,000 to be matched by a like appropriation from Federal funds; for coöperative topographical and geological work with the United States Geological Survey, $10,000, which also is to be matched by a similar Federal appropriation; for general geological economic investigation of the mineral resources of the state, $5000."

The new bureau will therefore be the means of expending in mining, metallurgical investigations and in geological and topographic surveying the sum of $55,000 during the present biennium. The coöperative work in topographic surveying will be fully of as great a value to the agricultural and forestry interest of the state as to the mining industry, and for that reason the bill had the general support of all communities. Washington, Oregon and California each have a well organized survey of this kind and the creation of such a bureau of survey has been urged in Idaho for many years and has finally become a reality.

PENNSYLVANIA

Anthracite

Lofty—The Lehigh Valley Coal Co. has leased coal lands in Carbon and Schuylkill Counties to the Dodson Coal Co. The tract is near this town and is also near the former Silver Brook colliery, which was operated 15 years ago by Wentz & Co., under the name of the Silver Brook Coal Co. The Lehigh Valley company has been interviewing miners and former officials of the Silver Brook company concerning their knowledge of the worked-out areas in the old workings of that company.

Freeland—Pennsylvania state agricultural officials have opened an office at this place, and are fighting the "potato wart" disease which has broken out in the mining villages surrounding Hazleton. The coal companies are coöperating by furnishing steam and other aids, in the fight against the disease.

Hazleton—The Cranberry Creek Coal Co., west of town, is changing its pumping equipment from steam to electricity and, where conditions permit, drill holes through the rock are being used as column outlets instead of the column lines formerly used.

Berwick—Four operations have been started to dredge coal from the Susquehanna River, and another party is preparing to do the same. All expect to get more coal from the river this year than formerly. A Scranton firm erected a washery on the east side through which river coal is run. It finds a ready market for the hundreds of tons taken out daily.

Weatherly—The Supreme Court of Pennsylvania on Apr. 22 decided that where employees of a coal company are sent to a hospital for treatment for injuries by permission of a company, the latter is responsible for payment of the bills. The opinion was rendered in the case of the Middle Coal Field Hospital against the Lehigh Valley Coal Co.

Wilkes-Barre—As the result of a fire that started in the twelve east gangway of the Nottingham mine of the Lehigh & Wilkes-Barre Coal Co. at Plymouth on May 3, fifty men nearly lost their lives. All were brought to the surface, however, though many of the men are in a serious condition. The men were overcome by blackdamp, falling in rows along the gangway.

Mahanoy City—Deeds were recorded on Apr. 29 conveying a large tract of land in Union, West Mahanoy and Butler Townships from Louis V. Gerhardt, of Paris, France, to the Wentz Corporation, organized and existing under the laws of Virginia and from the Wentz Corporation to the Raven Run Coal Co. The consideration in each case was $28,333.33 and the extent of the transaction involved 37 and 21/27 twelve hundredths parts of the entire tract of 1200 acres.

Freeland—The Pond Creek Coal Co. will resume operations at its mine as soon as the colliery can be reopened. This mine was closed during the slack market period.

Carbondale—A petition has been presented to the city council by property owners of Canaan St., asking the council to restrain the Tappan Coal Co. from further mining operations until the mine fires which have been burning for several years be extinguished.

Scranton—Maintaining the rate established by court in 1916, the county commissioners of Lackawanna County have set the triennial assessment on coal lands in the county, which will stand until 1922, at $300 per foot-acre. Coal lands in Lackawanna County under the present assessments, with a tax of three mills and a valuation of approximately $57,000,000, bring in about $175,000 in county taxes, about 80 per cent. of it being paid by the coal companies.

Pottsville—A cage containing ten miners dropped 1100 ft. at the Maple Hill shaft of the Philadelphia & Reading Coal and Iron Co. on May 5, resulting in the death of one miner and serious injuries to the nine others, two of whom may die.

Minersville—One of the greatest fires this region has ever seen is raging at the Lytle colliery timber and culm bank. Refuse timber and coal dirt from the mines has been thrown for years on this dump, almost mountain high, and fire, starting in the very heart of the bank, has such a stubborn hold that great streams of water have failed to extinguish it. The Susquehanna Collieries Co. has a large number of men fighting the flames.

Dorranceton—Two men were killed and three other workers injured on Apr. 29 as a result of a gas explosion which occurred in the Pettebone mine of the Delaware, Lackawanna and Western R.R., Coal Department. It is thought the accident was due to carelessness on the part of one of the doorboys. The supposition is that one of the door tenders failed to do his duty in closing a door after a locomotive had passed through and thereby allowed gas to collect. It is believed that sparks from an electric locomotive ignited, causing the explosion. The explosion did not cause a fire, but completely wrecked a portion of the mine.

West Hazelton—The Alliance Coal Co. workings at Kaska William, which have been flooded with water for many years, will be freed by electric pumps now being installed.

Bituminous

Uniontown—The Whyel Coal and Coke Co., Harry Whyel, president, has purchased from the C. S. Bygate Estate of Pittsburgh, Penn., the 153-acre tract of coal known as the Whitehead tract in the Irwin gas coal basin in Westmoreland County, Penn. and is preparing to open a mine on it. It will require a shaft about 300 ft. deep and 6000 ft. of railroad.

Waynesburg—G. M. Scrugham, D. M. Hertzog and R. M. Hite, trustees of J. V. Thompson, in bankruptcy, have sold to the Cumberland Coal Co. a block of Pittsburgh vein of coal in the eastern part of Franklin township, aggregating about 1168 acres; consideration, $450,654.30. W. Harry Brown, of Pittsburgh, has sold to the Buckeye Coal Co. one-seventh interest in four tracts of coal in Cumberland township; consideration, $1. C. C. Jordan has sold to the Cumberland Coal Co. coal under a lot in Jefferson borough; consideration, $257. Annie B. Luse, of Carmichaels, has purchased from Dr. W. M. Parry, of Waynesburg, and Dr. Roger S. Parry, of Washington, a tract of Pittsburgh vein coal in Aleppo township, containing 104.-1675 acres; consideration, $7,812.56. Dr. Roger S. Parry, of Washington, has purchased from E. E. White 104.1675 acres of Mapletown or Sewickley vein coal in Aleppo township; consideration, $1. H. G. Rockwell, of Chicago, has sold to the Cumberland Coal Co. one-half interest in two tracts of coal in Whiteley township, equal to about 49 acres; consideration, $1. [The Cumberland Coal Co. is a subsidiary of the H. C. Frick Coke Co.—Editor.]

Uniontown—The Thompson tangle, dormant for several months, came to the front again here with the hearing upon a petition to dissolve the Thompson creditors' committee on the ground that it had long ago ceased to function. The hearing developed the fact that another deal is now pending for the sale of the involved estate and that negotiations have been well advanced. The negotiations with the unnamed purchaser are being conducted by J. V. Thompson, with assistance being given both by the trustees in bankruptcy and the members of the creditors' committee. The fact that a sale is now pending was introduced to show that the creditors' committee still is functioning.

Connellsville—W. J. Culleton and M. A. Buriss, superintendents of the H. C. Frick Coke Co., have exchanged plants. Mr. Culleton, who has been superintendent of the Phillips mine, has been transferred to Footedale and Ronco. Mr. Buriss, in charge of these mines, has gone to Phillips. Employees of each plant presented remembrances to their "super" upon his departure.

WEST VIRGINIA

Caples—The Central Pocahontas Coal Co. has recently completed negotiations for the purchase of the Standard Pocahontas Coal Co. The property includes a total of about 1900 acres of coal lands, with mine, dwellings, etc., having a capacity of about 10,000 tons per month. It is understood that the company is arranging plans for further development at an early date, to increase this amount to a total of 25,000 tons per month. Headquarters of the company are in the Payne Building, Welch, W. Va.

Fayetteville—Progress is being made by the East Gulf Coal Co. in the improvements being made at its plant at East Gulf, in the Stone Coal field, 30 new miners' dwellings being now under construction.

Williamson—After having been suspended for the greater part of the winter, operations will be resumed at practically every mine on Pond Creek, Mingo County, in the near future. This has been made possible through additional orders recently received.

Glen Alum—The Glen Alum Coal Co. will complete work in the near future on its No. 3 plant and will therefore be in position to mine and ship coal from that plant in a few weeks. The company has recently received orders which will insure full-time operations throughout the summer.

Bluefield—Summer improvements at the Coalwood plant of the George L. Carter Coal Co. will include the erection of a large steel tipple, an automatic hoist and a large number of company houses. Both at Coalwood and at Seaboard a number of men are now engaged in getting the mines in readiness for future activities. The shaft at the Coalwood plant reaches 19,000 acres of a 7-ft. seam of Pocahontas coal. The holdings of the Carter Coal Co include 40,000 acres in West Virginia, Kentucky, Tennessee and Iowa.

KENTUCKY

Whitesburg—A number of operators in the Elkhorn fields have recently secured contract orders for shipment to the Lake trade, and feel much better concerning the prospects for summer business. It is reported that several of the operators see full-time operations ahead of them.

ALABAMA

Birmingham—A gas explosion in the Regal mine of the Majestic Coal Co. at Pinson, in the northern portion of Jefferson County, Apr. 29, resulted in the death of 21 employees, included in the number being the master mechanic of the company. Seven other men were taken to a local hospital seriously injured, and further fatalities may result. Only a small number of the men were burned by the explosion, the majority of the deaths resulting from suffocation from the fumes. The physical damage was confined to the inside of the mine and operations will be resumed in the course of a week.

OHIO

Wilbern—The Wayne Coal Co., of Pittsburgh, will soon start another stripping operation at this place. An additional 2000 acres of coal lands has been acquired and equipment is now being installed. It is expected to have the operation working by July 1.

Crooksville—The New York Coal Co. has opened up a 3500-acre block of coal adjoining the old workings of its mine near Rose Farm, and is arranging to operate the mine on a much larger scale than formerly. With the opening up of the lake trade, the output of the mine will reach 1500 tons per day.

INDIANA

Brazil—A tract of 118 acres of coal land three miles south of Harmony, belonging to Lewis McCollough, has been sold to E. Williams, of Paris, Ill., who will develop the coal under the land at some later period.

ILLINOIS

Du Quoin—The large plant of the Security Coal and Mining Co., of Missouri, owned by the Rutledge & Taylor Coal Co., Chicago, has resumed operations after a shutdown of two weeks. During this time a new railroad scale has been installed and general repairs made throughout the mine. The scale was put in by the Howe Scale Co. and was manufactured at Rutland, Vt. A much better outlook is reported for steady work at this mine in the near future.

Tamaroa—The Victory Collieries Co., at Tamaroa, north of Du Quoin, is installing a modern coal crusher which will increase the market value of its output. This mine was purchased two years ago by Dowell & Lafont, of Du Quoin, well known land dealers in southern Illinois, and reopened and then sold again to the present owners. Since its reopening it has increased in size and output 200 per cent.

Harrisburg—Reports coming from Saline County, mainly the mines surrounding Harrisburg and the O'Gara mines, say that mining conditions are almost at a standstill. In addition to the mines being idle, the Big Four R.R. has made slashing reductions in its yard forces and it is stated that many men have been laid off for as many as 60 to 90 days. No hope is held out for the mines to resume more steady work for at least three months.

Carlinville—The vast developments of the Standard Oil Co. are rapidly shaping into completion. One large mine has been completed and opened since last May. The other shaft at Shoper reached coal three months ago, and the machinery is fast being installed. The power plant which, it is said, can furnish enough power to run fifty mines, is almost finished. The railroad has been completed as far as Shoper. A big dam for a water reservoir is finished and the addition of 200 houses in Carlinville is about to be opened, with all houses completed.

Belleville—The St. Louis & O'Fallon Coal Co., after being fined $25 and costs by a justice of the peace on each of three charges of violating the state mining law by failing to provide suitable washroom facilities at the so-called Nigger Hollow Mine No. 2, has announced that it will appeal to the Circuit Court. The charges were brought by State Mine Inspector Thomas Wright, and were substantiated by the testimony of miners.

Edwardsville—Work was begun recently on the steel tipple of the new Donk Bros. mine here, which is to have the largest shaft in southern Illinois.

Alton—The Moro Coal Co., failing to get the Big Four R.R. to move to its line, near Moro, will move its mine to the railroad. The company bought the old Kable mine more than a year ago and on the advice of experts sank the shaft at some distance from the railroad, in the expectation that the railroad company would build a spur to the mine. But the railroad company has declined to do so and the coal company has failed to induce private capital to build the spur, so another shaft is to be sunk right up close to the railroad. Work was begun on it a few days ago. John Kekich, of Alton, is head of the company. The company has about 1000 acres of coal.

TEXAS

Rockdale—Axford Hicks, of Tyler, Tex., has leased 1000 acres of land near Rockdale, in Milam County, Texas, and is sinking a number of test holes in an effort to locate lignite veins. It is his intention, if lignite is found in paying quantities, to open up a large mine.

MONTANA

Havre—A 7ft. coal seam has been uncovered on the Pat Yeen ranch here by well drillers, at a depth of 150 ft. The coal resembles the Lethbridge coal.

Great Falls—Deeds have been placed on record by which coal lands between Belt and Sand Coulee have been transferred to the Anaconda Copper Mining Co. for a consideration of $158,000. It is understood the company purchased these lands with a view of making them into its chief coal

mines in northern Montana upon the exhaustion of its mines at Tracy, which is looked for within the next three years.

WASHINGTON

Wenatchee—The main shaft of the Wenatchee Orchard Land Co. coal mine near Appledale has penetrated to the coal seam, which has been found to be 10 ft. thick.

Walla Walla—While driving a well on the George W. Glouck farm near Atkins, at a depth of 490 ft., a large vein of lignite was uncovered, samples of which burned well under test.

Spokane—W. S. Rogers has been elected president of the Colville Valley Coal Co. A. N. Cantril, secretary and treasurer, and Joe Budersdorf, as manager, were reelected. Work is proceeding in the development of the company's mine near Colville, about 350 ft. of tunnel and 170 ft. of shafting being completed to date.

Foreign News

Princeton, B. C.—Railway construction men on strike here became troublesome toward the end of April and are charged with responsibility for a fire which broke out at the Princeton Coal and Land Co.'s plant. That the fire was incendiary in its origin is indicated by the fact that the hose, with which an effort was made to control the flames, was found to have been cut. While no definite particulars have been secured as yet, it is not believed that serious damage resulted. Detachments of the Royal Northwest Mounted Police have been dispatched to the scene and it is confidently expected that order will be restored in a short time.

Victoria, B. C.—Satisfactory progress is being made in the opening of the new No. 3 Mine of the Merritt Collieries, Ltd. Two slopes have been driven as well as two levels. Thomas Rowbottom is in charge of the work.

The Canadian Western Fuel Co. is continuing the development of the Wakesiah mine. This work was pressed forward for some months and then stopped. Its resumption is taken to indicate the company's intention to put the mine on a producing basis as soon as possible.

Suquash, V. I.—The Pacific Coast Coal Mines, Ltd., has pumped the water out of its old mine at Suquash, Vancouver Island. This property has been idle since the year 1914. With a ready market and good prices, it is likely that the company purposes making it productive without delay. This mine is situated in what is known as the Suquash Coal Field of the Island, approximately 170 miles north of Nanaimo, B. C. Comparatively little active development has taken place in that section.

Halifax, N. S.—Representatives of the Nova Scotia Steel and Coal Co. and the Dominion Coal Co. are pressing their claims upon the Provincial Legislature with regard to enabling each company to obtain access to submarine coal deposits, hitherto inaccessible to the owner except through the property of its competitor. The companies having failed to get together and come to an understanding, as requested by the Provincial Government, it is announced that legislation will shortly be introduced to compel the companies to exchange coal areas on fair terms. While this would not affect the Dominion Coal Co. to any great extent, as it has ample reserves of unworked coal adjacent to its present workings, it would be most advantageous to the Nova Scotia Co. whose present workings are nearly exhausted and whose reserves would then be rendered accessible.

Winnipeg, Man.—Official records show that a total of nearly 600,000 tons of hard and soft coal came into Winnipeg between June 1 and Mar. 1, of which about 360,000 tons was shipped from the western mines. W. P. Brereton, city engineer, stated that "western coals have done splendid work at the city's high pressure plant, where most of the city's municipal purchases have been used." Archibald Blackie, city chemist, says that the analysis gave the best record for any soft coal the city has had, most of the samples examined for the city under guarantee orders showing the western coal to be higher in B.t.u. values than the standard required. The percentage of ash was also lower than required by the guarantee.

Victoria, B. C.—In placing coal mines in British Columbia under the income tax law for purposes of taxation, the Government has been guided by the recommendation of a taxation board, which was appointed two years ago for the purpose of investigating the present provincial methods of obtaining revenue and making any suggestions considered wise for the removal of inequalities and the better distribution of the burden. The board's report, which was laid before the Provincial Legislature during its last session, gives considerable attention to the taxation of mining but, for the most part, its comments are directed to the situation in respect of metalliferous mining. Among its proposals, however, was that which was adopted—namely, the bringing of the collieries under either the 10c. per ton royalty or the income tax law, the Government to collect whichever method yielded the greater revenue.

Personals

John L. Briton, of McAlester, Okla., was elected vice president of District 21, United Mine Workers of America, in a special election recently held in the district.

Major D. B. Wentz, president of the Wentz Companies, has returned from France and is expected to visit the anthracite collieries of the company in the near future.

J. B. Neale, production manager during the war for the Fuel Administration, has been summoned by the President and will sail for Paris at an early date. No details of the import of his mission are available.

I. D. Thomas, of Hazleton, Penn., on Apr. 30 was appointed superintendent of the East Bear Ridge mines near Frackville, Schuylkill County. He was formerly manager of the Harleigh Brookwood Coal Co. at Harleigh.

William Crooks, who has been connected with the Tennessee Coal, Iron and Railroad Co., has assumed the position of superintendent of the Montevallo Mining Co. at Aldrich, Ala., taking the place left vacant by the recent resignation of **T. W. Lloyd.**

H. B. Payne, House Building, Pittsburgh, Penn., has been appointed district factory representative for bituminous fields of Pennsylvania and all of West Virginia by the Atlas Car and Manufacturing Co., of Cleveland, Ohio, handling the Atlas line of storage-battery locomotives.

J. B. Crankshaw, former manager of the Cranberry Creek and Alliance Coal Companies, accompanied by Mrs. Crankshaw, has sailed for his former home in London, England. Mr. Crankshaw will be associated with his father in an important English engineering company.

Edwin Ludlow, for the past ten years vice president of the Lehigh Coal and Navigation Co. has resigned, effective July 1. **W. G. Whildin**, a Lansford man, who has been a life-long employee, will succeed him. **J. P. Warriner** will continue as manager of the Cranberry Creek and Alliance Coal Companies.

W. P. Engleman, of New York City, has been retained as chief engineer of the Domestic Coke Corporation of Fairmont, W. Va. Mr. Engleman, during the war, was in the service of the Government as a coke and byproduct expert. He has resigned his Government position and has established his headquarters in Fairmont.

F. J. Dawson has been appointed assistant to the general manager of the Raleigh Coal and Coke Co., Huntington, W. Va., his appointment being effective May 10. Mr. Dawson has been general inspector and consulting engineer for all the smokeless fuel operations in the state. He is by profession a civil and mining engineer, his experience having taken him to England, Scotland, Wales, Mexico and Canada.

Charles F. Colbert, Jr., of Brownsville, Penn., for the past eight years sales manager, and recently also assistant general manager of the W. Harry Brown coal and coke interests, and who since the sale of these properties to the Pittsburgh Steel Co. has been looking after the closing up of the transfer of the properties, has severed his connection with these properties and taken an interest in and the position of general manager of the Pioneer Coal and Coke Co., a recently organized brokerage concern with offices in the Henry W. Oliver Building, Pittsburgh, Penn. He will sell his property in Brownsville and move to Pittsburgh.

Obituary

Robert Lake, well known throughout Michigan, Ohio and Indiana as a coal merchant, having served as president of the Tri-state Coal Association, died in Jackson, Mich., on Apr. 29.

Coming Meetings

American Wholesale Coal Association will meet on June 3 at Cleveland, Ohio. Secretary, L. Romanski, Chicago, Ill.

Illinois Mining Institute will hold its annual meeting May 22, 23 and 24. Secretary, Martin Bolt, Springfield, Ill.

National Coal Association will meet May 21, 22 and 23, at Congress Hotel, Chicago, Ill. Secretary, J. D. A. Morrow, Washington, D. C.

Illinois and Wisconsin Retail Coal Dealers' Association will meet at Hotel Nelson, Rockford, Ill., June 4 and 5. Secretary, I. L. Runyan, Chicago, Ill.

International Railway Fuel Association will hold its annual meeting May 19-22 at the Hotel Sherman, Chicago, Ill. Secretary, J. G. Crawford, Chicago, Ill.

Retail Coal Dealers' Association of Texas will hold its annual meeting on May 19 and 20 at Fort Worth, Tex. Secretary, C. R. Goldman, Dallas, Tex.

Central Pennsylvania Producers' Association will hold its annual meeting May 15 at Chamber of Commerce Building, Altoona, Penn. Secretary, Charles O'Neill, Altoona, Penn.

Southwestern Interstate Coal Operators' Association will hold its annual meeting June 10 in the Keith and Perry Building, Kansas City, Mo. Secretary, C. N. Fish, Leavenworth, Kan.

American Society of Civil Engineers will hold its forty-ninth annual convention in St. Paul and Minneapolis, Minn., June 17 to 20. Secretary, C. W. Hunt, 33 West 39th St., New York City.

Mine Inspectors' Institute of the United States of America will hold its annual meeting July 8 to 11 at Indianapolis, Ind., subject to ratification of executive committee. Secretary, J. W. Paul, Pittsburgh, Penn.

National Retail Coal Merchants' Association will hold its annual convention at Buffalo, N. Y., May 14-16, with headquarters at Lafayette Hotel. Secretary-Manager, E. B. Gordon, 1727 Pennsylvania Ave., Washington, D. C.

Kentucky Mining Institute expects to hold its annual meeting this year on May 30 and 31 at Lexington, Ky. Secretary, C. W. Strickland, Huntington, W. Va.

American Institute of Mining and Metallurgical Engineers will hold its fall meeting Sept. 22 to 26 in Chicago, Ill. Chairman Chicago meeting, Carl Scholz, 547 West Jackson Boulevard, Chicago, Ill.

American Society of Mechanical Engineers will hold its spring meeting at the Hotel Statler, Detroit, Mich., June 16 to 19. Secretary, Calvin W. Rice, 29 West 39th Street, New York City.

Trade Catalogs

New Book of E. M. Synchronous Motors. Electric Machinery Co., Minneapolis, Minn. Bulletin 501. Pp. 42; 8½ x 11 in.; illustrated. Describes briefly and simply the construction, characteristics and the applications of the synchronous motor.

The Nixon Ratchet Mining Drill. The Bonney-Shanks Co., Chattanooga, Tenn. Catalog. Pp., 8; 6 x 9 in.; illustrated. Describes in detail the manufacture and operation of a practical ratchet drill for driving entries and airways, taking top and bottom, and mining hard coal.

Fifty Years of a Successful Industry. The Yale & Towne Manufacturing Co. Souvenir Booklet. Pp. 76; 5½ x 8 in.; illustrated. Commemorative of the completion of 50 years of activity by the corporation. Is of interest as illustrative of the origin and development of one of the well-known American industries.

"Over 1000 Scoop Conveyors." Portable Machinery Co., Passaic, N. J. Folder Pp. 20; 6x9 in.; illustrated. Shows the various uses of the scoop conveyor and describes clearly the labor, time and money-saving features of the machine in storing, reclaiming, loading and unloading loose materials.

Reducing Ash-Disposal Costs. American Steam Conveyor Corporation, Chicago, Ill. Booklet. Pp. 12; 8½ x 11 in.; illustrated. Of interest to engineers and power plant executives will be the diagram and description of an ash conveyor that paid for itself in eighteen months. Diagrams and photographs of actual installations are used to liven the booklet.

Lidgerwood Coal-Handling Cableways. Lidgerwood Manufacturing Co., New York, N. Y. Bulletin 34. Pp. 10, 9 x 12 in., illustrated. Covers a cableway for coal-storage purposes. It is claimed that with the aid of the device described and illustrated in the bulletin, coal can be successfully stored where the ground available could hardly be utilized with any other method.

Industrial News

Pittsburgh, Penn.—Gellatly & Co. and the Ohio Brass Co. announce that they are now located in Suite 2205-06 Oliver Building.

Indianapolis, Ind.—Dean Bros. Steam Pump Works have opened a New York City office at 141 Broadway. H. Meachem has been appointed district sales manager.

Whitesburg, Ky.—The Caudill Coal Co., at Caudill, Ky., has changed its name to the Solon Coal Co. Williamsburg and Whitley City interests control the company.

Chicago, Ill.—On May 1 the local office of the Ohio Brass Co., of Mansfield, Ohio, was moved from 508 Fisher Building to 1217 Fisher Building, 343 South Dearborn St. The telephone number has been changed to Harrison 4343.

Hartford, Conn.—The Terry Steam Turbine Co. announces the appointment of R. L. Thomsen as sales manager. Previous to his appointment, Mr. Thomsen was manager of the Marine Department for the Griscom-Russell Co.

Cincinnati, Ohio—The Pocahontas Coal Sales Co. and the Glen Alum Fuel Co. announce that they have removed their western office, in charge of John R. Miller, from 1405 to 1207 Fisher Building. The telephone number is Harrison 5414.

New York, N. Y.—Greene, Tweede & Co., 109 Duane St., manufacturers of Palmetto and other packings, have issued a new catalog which in effect is a guide book to the use of packings. It contains much of value to those who use and buy packings, and will be sent free of charge upon request.

Hazard, Ky.—It is reported that the Thornton Creek branch of the Louisville & Nashville R.R. will be extended into the Headwaters division of the section, tapping additional coal and timber districts which have been waiting on rail connections.

Cleveland, Ohio—Drusus H. Nichols and John C. Moore, formerly managing director and assistant director of the Allied Publicity Bureau, announce the organization of the Nichols-Moore Co., general advertising agents, to be located at 11705 Detroit Ave., Cleveland.

Wilmington, N. C.—The Cement Products Co., manufacturer of the "Sanisep" sewerage disposal systems, with main offices at Wilmington, N. C., has opened a branch sales office at 39 Cortlandt St., New York, which is in charge of J. F. Harris, vice president of the company.

Pittsburgh, Penn.—The Pittsburgh Mining Machinery Co., with offices in the First National Bank Building, has recently completed extensive improvements at its factory for rebuilding and repairing mining machines, locomotives, motors, etc. The new shops are at Magnolia and Cantril Sts., North Side.

Jersey City, N. J.—The Joseph Dixon Crucible Co., manufacturers of silica-graphite paint, crucibles, graphite greases and graphite lubricants, have announced the removal of their Philadelphia sales office from 1020 Arch St., to Rooms 801 and 802 of the Finance Building, South Penn Square, Philadelphia, Penn.

Charleston, W. Va.—The Malleable Coal Co. is understood to be arranging plans for the construction of a large coal tipple at its coal-mining properties, and the building of two additional miles of railroad line. It is said that the company is planning for the development of new coal-mining properties in addition to its present works. Samuel Butler is manager.

Indianapolis, Ind.—It is reported that the Neal Gravel Co., Indianapolis, Ind., plans to double the capacity of its plant at Attica, which will necessitate the purchase of engines, boilers, crushers, screeners and gravel-removing equipment, possibly a new steam shovel. This is to be the largest plant of the four owned and operated by the company. It also owns two or three coal mines.

Baltimore, Md.—The Black & Decker Manufacturing Co., builders of portable electric tools, electric air compressors and special machinery, has established a New York office at Room 2920, Equitable Building. The office will be in charge of G. R. Lundane, who will supervise the distribution of the company's products in New York city and surrounding territory, including the State of Connecticut.

Buffalo, N. Y.—The Copper Coal Co., of Brockwayville, Penn., has been incorporated in this state under the same name, with W. C. Quinn, president of the parent company, and George B. Burd and A. C. Hynd, of Buffalo, incorporators. Capital stock is $200,000. The idea is to sell the coal, which comes from the Argentine mine in Butler Co., Penn., through this market and possibly open an office here.

Frankfort, Ky.—The State Railroad Commission has been advised of the completion of the 10-mile coal-carrying railroad of the Black Mountain R.R. from Huline, Bell County, Kentucky, to the Louisville & Nashville junction in Harlan County. Offices are in Pineville, and the line will be placed in operation as soon as necessary eqiupment arrives. This will open up shipping for several new mines.

Toledo, Ohio—D. H. Goodwillie, service director, will receive bids until June 3 for installing coal-handling equipment consisting of (a) one track hopper coal crusher and elevator and conveying machinery, (b) one suspended steel coal bunker with supports, (c) one traveling weigh hopper, all to be erected complete at the Broadway Pumping Station. H. C. McClure, Valentine Building, Toledo, Ohio, City Engineer.

Cinncinnati, Ohio—The City of Covington, across the river from Cincinnati, has passed an ordinance that will eliminate the temporary coal merchant. The ordinance provides a license of $500 for a temporary merchant. The coal men claim this will be an equal protection for other merchants as well as themselves. The new ordinance will make it unprofitable for the individual dealer to enter the coal business for a few months during the winter season.

Fairmont, W. Va.—Directors of the Consolidation Coal Co., at a meeting in Baltimore recently, elected Frank R. Lyon, of Fairmont, a vice president and placed him in charge of all operations of the company. Brooks Fleming, Jr., of Fairmont, was made assistant to the president and will likely be Mr. Lyon's assistant in the company's operations, which embraces numerous mines in the States of Maryland, West Virginia, Kentucky and Pennsylvania. For six years Mr. Lyons has been general manager of the company.

Seattle, Wash.—To investigate terminal facilities and improvements in transportation necessary to handle the output of the navy coal lands at Cook Inlet, Alaska, Captain Sumner, E. W. Kittelle and Capt. L. E. Gregory, U. S. N., are on their way to join a party of scientists in Alaska who will handle a part of the investigation work. The navy is planning to bring Alaska coal into use, and the facilities needed at the Matanuska fields, which will be investigated, and the expense of installing transportation and terminal works, will be covered in the report to be submitted to guide the making of appropriations for the purpose. The party will be absent about six weeks and will work from Anchorage as a base.

Jefferson City, Mo.—Missouri now has a workmen's compensation law. The bill as amended and passed by the Senate was passed by the House Thursday, May 1, by a vote of 125 to 4. It is to be administered by a bi-partisan commission of four, one member of which shall represent the employers and one the employees. The commissioners will be paid $4000 a year each. The bill becomes effective Nov. 1. It provides for medical aid for the first eight weeks at a cost of not to exceed $200. Compensation is to be on the basis of 66⅔ per cent. of wages, computed on the annual average, the maximum to be $15 per week and the minimum $6 per week. Temporary total disability is not to exceed 400 weeks. For temporary partial disability the provision is two-thirds of the wage loss, not exceeding 200 weeks. For permanent total disability the compensation is to be two-thirds wages for 240 weeks and thereafter 40 per cent. of wages for life. The burial benefit is $100 in every case and total dependents are to receive two-thirds of wages for 300 weeks. All insurance for employees is to be procured from private companies. Employers and employees may elect whether to come under the law's provisions.

Anthracite Industry Busy, While Bituminous Market Is Still Stagnant—Better Conditions In Soft Coal Looked for Soon—Some Price Cutting Reported—Scarcity of Egg Coal

IT IS interesting to note the contrast presented by the anthracite and bituminous branches of the coal industry at the present time. In the hard-coal regions activity is everywhere in evidence, while in the sections where bituminous coal is mined many operations are barely working. The reason for this difference will readily be appreciated when it is understood that anthracite coal is used principally by domestic consumers, while bituminous coal is consumed by the industries. Of the 90 million tons of anthracite produced yearly, probably 70 million tons is burned for domestic purposes; the domestic consumption of bituminous coal, on the other hand—70 million tons — is negligible when compared to the large annual output.

However, better days are coming for the soft-coal operators, as increased activity is discernible in industry in general. Once the Victory Loan is successfully closed and out of the way, and the political turmoil in Europe quiets down, plants the country over can begin to extend their operations and count on the necessary banking assistance to enable them to do so. When the present uncertainties besetting shipping, price regulation and public utilities are removed, it will mean a renewal of prosperity; and a renewal of prosperity means an augmented demand for fuel. The two are inseparable.

Still, it must be recorded with regret that though an improvement is observed in soft-coal conditions from week to week, the change is barely perceptible. There is quiet buying here and there, but the tonnages are not large enough to exert any material effect on prices. There is plenty of spot coal available, and thus steam-coal users see no necessity at this time for haste in the closing of contracts for their future requirements. Railroad buying, in the main, is still shrouded in mystery, though it has been made public that the Pennsylvania lines east of Pittsburgh have contracted for a large tonnage of run-of-mine at the former Government price.

In the anxiety to dispose of coal, some of the Middle West operators are reported to have released their output at comparatively low prices, and the same has been said of operators in the Eastern fields. This tendency to recede from the announced intention of curtailing production rather than selling coal at a loss is not true of the industry as a unit. In fact, prices are being adhered to firmly, and the output of only 7,362,000 net tons of bituminous coal during the week ended April 26 is proof conclusive that the rate of production is still far behind the rate of consumption.

If plans of the Government materialize, much of the stagnation in the bituminous coal industry will be eliminated by the export of a large volume of coal. The necessary ships have been promised by July, and the soft-coal operators, through the National Coal Association, have signified their willingness to coöperate in every way possible.

So great has been the demand for the domestic sizes of anthracite that already the mines are unable to ship the necessary tonnages. The call from consumers for prompt delivery of coal that will not be burned until next fall is reflected in a growing shortage of egg coal. Many of the mines have sufficient orders on their books to carry them through the month of July, and even the steam sizes of anthracite are being called for in increasing volume. The prices of these coals have tightened considerably. During the week ended April 26 the anthracite mines produced 1,401,000 net tons of hard coal.

WEEKLY COAL PRODUCTION

Bituminous coal production during the week ended Apr. 26 is estimated at 7,362,000 net tons, and is a slight falling off compared with the output of the week of Apr. 19, estimated at 7,413,000 net tons. During the same week of 1918 the operators of the country produced 11,720,000 net tons. The daily average per working day during the current week is estimated at 1,227,000 net tons, as against 1,235,000 net tons during the week preceding and 1,358,000 net tons for the calendar year to date. For the period of Jan. 1 to Apr. 26, 1919, the production of bituminous coal is estimated at 135,759,000 net tons, and falls 42,313,000 net tons, or 24 per cent., below the output of the same period of 1918, estimated at 178,072,000 net tons.

The production of anthracite in the United States during the week ended Apr. 26 is estimated at 1,401,000 net tons, as compared with 1,568,000 net tons for the week ended Apr. 19, and 1,870,000 net tons during the corresponding week of last year. The daily average per working day during the week ended Apr. 26 is estimated at 234,000 net tons, as compared with 237,000 net tons, the daily average for the calendar year to date and 312,000 net tons, the daily average for the same period of 1918. For the calendar year to date, production of anthracite is estimated at 23,662,000 net tons for the corresponding period of 1918.

Shipments of bituminous coal from the tidewater harbors to all points during the week ended Apr. 26 are estimated at 453,074 net tons, as compared with 405,117 net tons during the week preceding, and 873,630 net tons during the same week of last year. During the current week improvement occurred at all harbors with the exception of Philadelphia. The New England shipments of bituminous coal by tidewater during the week of Apr. 26 amounted to 102,789 net tons, as compared with 79,491 net tons during the week preceding. Tonnage was loaded at Baltimore for the first time since the week ended Mar. 29 and amounted to 3478 net tons.

Beehive coke production in the United States during the week ended Apr. 26 is estimated at 261,767, net tons, as compared with 294,848 net tons during the week ended Apr. 19, and 655,698 net tons during the week of Apr. 27, 1918. The current week's production, the lowest recorded in recent years, shows, when compared with the preceding year's production, the tremendous pressure which was brought to bear at that time to make available the amount of coke which was necessary for war purposes. During the current week, production fell off in all states, with the exception of those west of the Mississippi. Pennsylvania production continues on the downward grade, and is today but 40 per cent. of that recorded during the week of Apr. 27, 1918.

With the opening of the lake season, bituminous coal figures on dumpings at the lower lake ports are once more available, and beginning with this issue, will be a regular feature of the weekly report. During the week ended Apr. 19 the tonnage loaded amounted to 288,524 net tons, and was approximately 50 per cent in excess of the tonnage loaded during the same week of last year. For the season to date, the tonnage loaded amounted to 561,235 net tons, as compared with 288,186 net tons during the same period of 1918.

Atlantic Seaboard

BOSTON

A dull featureless market. Apparently no decision yet on railroad requirements for this territory. Operators in need of May and June orders and concessions made to get them. No change in outlook for contracts. Hampton Roads factors still struggle with only hand-to-mouth business available. Slight improvement noticed inland. Margin between spot prices and those for deferred delivery, especially where rehandling is involved. Anthracite shipments slowing up. Egg in short supply. Coal for New England railroads likely to be factor in slow movement of domestic sizes. Retail prices advanced in Boston.

Bituminous—The market drags along with no significant change. There is quiet buying here and there, but the tonnages are not large enough to have any effect on prices. Buyers are aware that spot business is what is particularly desired by the shippers, while all-rail or at tidewater, and many of them are temporizing by arranging only for May or June delivery, leaving until later in the season their decision as to making contracts. There has seemed no inducement thus far to close such contracts on the quotations available, except in the case of certain specialties. Steam-users who have the run of the market and can buy from a range of coals see no reason for haste in closing for their requirements.

It was supposed that by May certain doubtful features would be settled, but railroad fuel and season rates of freight on

barges and steamers from Hampton Roads are both undetermined, except in a limited sense.

Instead of the long-awaited spurt in demand it develops that operators are much in need of orders for May and June delivery. This is particularly true of those producers whose coals are less favorably regarded, although there is distinctly a strong selling effort in behalf of the highest grades from the Somerset and Cambria districts. In most cases concessions of 10c.@25c. have been made to secure spot business, and it is this sign of weakness that gives buyers the impression there is plenty of time for securing next season's supply.

As to contract quotations, there is no apparent change. Practically no concessions are reported, for as yet neither shipper nor consumer seems able as yet to sense what the situation will be next fall and winter.

The Pocahontas and New River shippers still have hard going in New England. Seldom are there any sales reported. One of the street-railway systems is receiving bids this present week, and on that portion of the tonnage to be taken at plants directly on tidewater there is much interest to see the result. Only scattering business seems to be available for the Hampton Roads shippers and their tonnage is extremely light for this market. Most of the business that could be closed easily was underwritten early in the season before the $2.75 per net ton f.o.b. mine basis went into effect, and on the latter figure only the most loyal of customers have been induced to make season arrangements. For the bulk of their tonnage inland the Hampton Roads distributors are obliged to rely upon quality and years of service to offset the heavy differential in favor of the all-rail coals, and it is a notable fact that there is now observed some improvement in the demand from this source.

There is still a pronounced margin between present prices for spot shipment on the Southern coals and quotations for extended delivery. For the latter $7.90 is the current figure per gross ton on cars Boston, while May deliveries have been offered rather freely on the basis of $7.20@7.35. There are still a number of West Virginia shippers who are offering standard Pocahontas and New River at $2.35 per net ton at the mines. Accumulations are the order of the day at the Virginia terminals, and with the exception of low grades from Pennsylvania there is today no class of coals on which the market is so druggy as the high-grade smokeless varieties from the Pocahontas and New River districts.

Bituminous prices current at wholesale are about as follows, f.o.b. mines and at loading ports, per gross or net tons as designated:

	Clearfields	Cambrias and Somersets
F.o.b. mines, net tons	$2.15@$2.75	$2.80@$3.25
Philadelphia, gross tons	4.20@ 4.90	5.00@ 5.30
New York, gross tons	4.50@ 5.25	5.35@ 5.70
Alongside Boston (water coal), gross tons	6.10@ 6.85	6.90@ 7.55

Georges Creek is quoted at $3.20 f.o.b. mines per net ton.

Pocahontas and New River are unchanged at $4.69@5.14 f.o.b. Norfolk and Newport News, Va., per gross ton, according to the shipper, for spot or contract. F.o.b. Boston the present gross ton range would be $7.20@7.65. It is understood that factors are still offering contracts on cars Boston for inland delivery at $7.90 per gross ton.

Anthracite—Since the last week in April shipments of domestic sizes have slowed up materially. Retailers who have stirred up the public to put in coal now find themselves unable to get cargoes forward in sufficient volume. All-rail there has also been a noticeable slackening in the tonnage of domestic sizes. The demand from the public for prompt deliveries now of coal that will not be used until next fall is reflected in the shortage of egg at most of the loading ports.

One of the ominous features of the current situation is the large tonnage which it is understood the Railroad Administration has ordered carried in Philadelphia & Reading barges to supply fuel for New England railroads at Portland, Maine, and points east. If carried through this will seriously curtail the space available to move domestic sizes in transportation that is normally the largest single channel of supply for tidewater New England. And this is done at a time when eighty or ninety steamers of the emergency fleet type are lying idle with no authority being exercised to put them into service. Something is wrong somewhere, and unless steps are taken to correct this particular situation there will be another anxious for the anthracite-consuming public.

On May 1 the Boston retail dealers advanced the price of broken, egg, stove and chestnut from $11, sidewalk delivery, to $11.50. Part of this advance is due to the situation at wholesale, but most of the 50c. increase is due to the recent wage agreement with teamsters and chauffeurs.

NEW YORK

Anthracite demand active, with some operators sold six weeks ahead. All sizes, particularly stove and egg, wanted. Canada sends many orders while the West is looking for quick shipments. The bituminous market slows down with prices showing a slight falling off. Buyers look for cheaper coals and hesitate to make purchases.

Anthracite—The long expected activity in the anthracite market is here, and both producers and dealers find themselves well supplied with orders. Many of the former, especially the so-called Independents, have orders sufficient to keep their operations going at full speed for several weeks to come. It was said in some quarters that some of the smaller operations have plenty of orders for domestic coals to keep them busy until the early part of July; in fact, it was said that some had sent word to dealers handling their product not to accept any more orders at present.

The larger companies are also crowded with orders and their operations are kept humming, most of the mines being reported as working nearly full time.

The trade expects an unusually busy summer as most cellars are far short of next winter's fuel supply, the consumers having delayed placing their orders in the expectation of a reduction instead of an advance in the price.

There is a heavy and an increasing call from Canada and the West, and coupled with it is a cry for quicker shipments. Consumers in Canada and the West are just as anxious to fill their bins as are the consumers here.

So far as the local market goes the heavier call is for stove and egg, but the other sizes do not lag far behind. Salesmen, however, have no difficulty in moving any of the other sizes, since dealers are willing to take any size in order to get what they want in the larger coals. Along the line the trade is active. Demand is heavy and the dealers are filling their bins.

Pea coal does not move so quickly as the larger sizes, but there is no anxiety regarding it. Whatever uneasiness existed last week regarding quotations has about disappeared, and reports of any slight concessions being made now are few and far between.

The steam coal situation has tightened considerably. Demand is good and there is comparatively little surplus coal to be seen at Tidewater. Quotations are firm, but slight concessions were heard on certain grades of buckwheat and barley.

Retail dealers report considerable activity. Consumers are now anxious to get their winter supply in before the summer vacations begin and are urging deliveries.

Current quotations, white ash, per gross ton, at the mine and f.o.b. tidewater at the lower ports, are as follows:

	Mine	Company Circular
Broken	$6.05	$7.90
Egg	5.95	7.80
Stove	6.20	8.05
Chestnut	6.30	8.15
Pea	4.90	6.65
Buckwheat	3.40	5.15
Rice	2.75	4.50
Barley	2.25	4.00

Bituminous—Conditions in the bituminous market are quiet and are reflected in quotations for the various grades of coal, which in the majority of cases show a decline from last week. Business is dull here and shippers, do what they will, are unable to convince buyers that the present is the time to buy.

Many buyers continue to cling to the opinion that they will be able to get coal at lower prices rather than pay higher prices next fall, and for that reason are holding back their orders. However, there are many who believe the turning point in the situation is not far distant. With it may come a complete reversal in present market conditions and a hustle to get coal. The mines are working scarcely better than half time, and the workers are not taking kindly to this program.

In this harbor the movement of coal since the end of the harbor strike has been a disappointment. It was expected that consumers would want to replenish their stocks and buying would continue to be heavy for several weeks to come. Many buyers after partly filling their bins curtailed their deliveries with the result that boat movement is slow and some shippers have had difficulty in getting rid of loaded boats unless they make concessions.

During the past week there has been a falling off in buying for commercial purposes, but bunker demand has remained brisk. Contract coals are moving rapidly, which enables shippers to keep their stocks at the docks down to a minimum.

While there has been a slight change in current quotations for spot coal for the various grades, shippers have not been forced to dispose of their stocks at low figures. As usual much depends upon supply and demand.

There have been many inquiries for coal for export, but no actual closings of contracts have been reported.

Dumpings of bituminous coal here for the week ended May 3 were 5955 cars, as compared with 5420 cars the previous week. During April there were 20,708 cars dumped as compared with 11,516 cars in March, 23,668 cars in February and 23,769 cars in January.

Current quotations for the various grades of bituminous, for spot shipment and on contract, follow:

	Spot	Contract
South Forks	$2.90 to $3.25	$2.95 to $3.50
Cambria County (good grades)	2.75 to 2.95	2.95 to 3.25
Clearfield County (good grades)	2.50 to 2.75	2.80 to 2.95
Reynoldsville	2.50 to 2.75	2.75 to 2.95
Quemahoming	2.65 to 2.85	2.95 to 3.10
Somerset County (best grades)	2.65 to 2.85	2.95 to 3.10
Somerset County (poorer grades)	2.00 to 2.35	2.50 to 2.75
Western Maryland	2.25 to 2.75	2.50 to 2.75
Fairmont	2.00 to 2.25	2.35 to 2.50
Latrobe	2.10 to 2.25	2.25 to 2.40
Greensburg	2.25 to 2.35	2.35 to 2.60
Westmoreland ¾ in.	2.60 to 2.75	2.60 to 2.75
Westmoreland run-of-mine	2.35 to 2.60	2.35 to 2.65

PHILADELPHIA

Strong demand for family sizes of anthracite. Business booked long time in advance. Heavy call for egg, making loss of broken tonnage less important. Pea improves. Price cutters increase their rates. Stove orders impossible to fill. Successful advertising campaign. Steam sizes show slight improvement. Bituminous dull and without feature. Little spot coal.

Anthracite—There is an intense demand for all the domestic sizes. All companies are jammed with orders, and those concerns who are willing to accept business for weeks ahead report heavy tonnages for shipment right up to July. The shippers are surprised at the amount of business for egg being received from the local trade. Except in the suburbs, the Philadelphia dealers formerly ordered a small tonnage of this size; but now the orders are out of all proportion to the production. This is particularly gratifying to the operators, for they have lost quite a lot of strictly commercial tonnage due to the turning of many gas companies to coke, which can now be purchased at a much lower relative price.

Stove size is in a hopeless state so far as the producers are able to fill orders for it. Every dealer is insistently calling for this size. At the offices of the larger shippers it is reported that sufficient orders for stove have been received in the last week or two to absorb the entire production for several months. Many yards are entirely bare of it, and no promises are being made as to when they can be stocked. Chestnut, too, is active, but a greater tonnage of this size seems to be coming here. Pea continues to be the size in least demand, but the improvement in this size has been so noticeable that promises of immediate shipment are no longer being made. The companies who had been compelled to send some of this size to storage yards are now able to send their full production directly into the market.

As anticipated, several of the price cutters who have always made pea coal their special point of attack have advanced their rates on this as well as the other sizes. The lowest figure at which pea coal can now be purchased at retail is $8.50, which is 50c. less than the dealers generally are charging.

The steam trade is slow to respond and appears to be something of a puzzle to all anthracite men. The big companies continue to stock while the smaller operators who are compelled to move their coal are

cutting prices and hoping for changed conditions. They report that some of their trade has gone over to bituminous; others over-bought and are now consuming their surplus stock. Yet it can be said there is actually some improvement in the steam sizes. Buckwheat is in much better demand and good improvement has been shown in the demand for rice. Barley is still hopeless, and no one really expects that it will improve for many weeks or even months.

No one can be found who is willing to venture a decided opinion on buckwheat, but it is apparent to some that the $3.40 price is hurting it. Some of the largest contracts carrying that price are still in the hands of consumers unsigned. In the meantime sales are reported around $2.85, with small lots at $3. As heretofore, rice is stronger than buckwheat, but is being offered at from $2.50 to $2.60. For barley a fair price is $1.50, and shippers are glad to get it.

The prices per gross ton for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$5 95	$7 80	Buckwheat	$3.40	$4.45
Egg	5 95	7 80	Rice	2.75	3.65
Stove	6 20	8 05	Boiler	2 50	3 50
Nut	6 30	8 15	Barley	2.25	3 15
Pea	4 90	6 50			

Bituminous—The trade continues quiet with practically no improvement during the last six weeks or more. Despite this colorless state of affairs shippers remain fairly optimistic that the turn in the road will soon be in sight. As it now stands, no one is willing to produce any more coal than is absolutely necessary to fill orders in hand. Most of the production continues to be aplied on contracts, and even such agreements as have been signed are not taking the full amount. Under such limited production there is of course little spot market.

All houses continue to receive numerous inquiries for prices on contracts, many being from the same consumers who have been asking figures for weeks past. They are simply sounding the market. While all shippers of consequence have received the proposition of the railroad authorities to supply fuel on the basis of a $2.40 to $2.50 price, it is not thought it has been accepted by many. The following are the prices which have ruled lately:

Georges Creek Big Vein	$2.90 @ $3.00
South Fork Miller Vein	2.90 @ 3.00
Clearfield (ordinary)	2.75 @ 2.90
Somerset (ordinary)	2.55 @ 2.70
Fairmont lump (ordinary)	2.40 @ 2.50
Fairmont mine-run	2.15 @ 2.25
Fairmont slack	1.90 @ 2.00

BALTIMORE

Increased activity in contracts follows some cutting on particular grades of bituminous. Wide range of quotations on both contract and spot coals of like quality. Hard-coal men here continue busy with deliveries. Exports look healthy.

Bituminous—There are undoubted signs of increasing activity in the contract market. For some weeks the trade heard of a number of inquiries on contracts, but few closings of importance were noted following the quotations of prices that held pretty well to the old Government maximum figures, even on the less desirable fuels. Now, however, quite a few consumers who want specialized coal have stopped purchasing in the open market, even at an advantage, and are closing at or near the old maximum. In addition there has been some decided cutting in contract quotations on fair to good coals in many instances, and this has stimulated buying.

Even on contracts on similar grades of coal, however, there is at times a considerable latitude of prices, and on some pretty good coals offerings were noted all the way from a mine basis of $2.50 to $2.95 to the trade. The spot market was spotty the past week, sales of best coals at tide being noted in a range of from $2.40 to $2.95 mine basis to the trade, of good coals not of special grading at from $2.20 to $2.80, and on less desirable coals at from $2.10 to $2.50, showing at times an overlap of prices on coals of decidedly different quality.

The export movement continues encouraging, and inquiries and orders are such that only the lack of bottoms prevents a considerable spurt in the movement. For the week ending Apr. 26 the Custom House reports total loadings on foreign account of 19,690 tons, including 1456 tons used by the carriers for bunker purposes.

Anthracite—The hard-coal dealers here continue busy making deliveries for May at the low price schedule of the year, the April cut having been maintained by the retailers for the month of May, at least. Some of the dealers are still delivering on orders placed the first half of April, not having received all the coal they ordered from mine connections. Wherever possible the trade is delivering promptly in order to keep yard forces moving at maximum and to get as much coal as possible from the mine connections. Chestnut still remains rather scarce here. Pea coal is the most liberal in supply.

Lake Markets

PITTSBURGH

Pennsylvania R. R. pays full price. Trade much encouraged. Contracts beyond Sept. 1 not popular. Production at about 50 per cent.

The Pennsylvania R.R. lines, east of Pittsburgh, has closed a contract with the Pittsburgh Coal Co. for 1200 tons of coal daily to the end of the coal year, at $2.35 for mine-run, the former Government price. The news came as a surprise to some in the trade, although not to those who have been strongest in their views as to the future of coal values and who had given due weight to the recent stiffening among producers. Earlier in the year the attempt to secure full Government prices was a half-hearted sort of affair, but in the past few weeks the leading operators have gone at the matter in a way that showed they really meant it; and for a fortnight past many operators have refused to contract for coal at the $2.35 price for deliveries running longer than to Sept. 1. However weak and uncertain the Pittsburgh district coal situation has seemed to be since the signing of the armistice, one fact stands out prominently, that for several weeks past it has been growing stronger.

The whole Pittsburgh district is feeling elated over the situation as now presented, but it has some interesting questions to answer. For instance, how gracefully can the operators continue their contention that the railroads and the general public should pay precisely the same price, when the Pennsylvania R. R. has accepted the $2.35 price? Also the contention of Pittsburgh operators that they were not given as fair a price, under Government control, as certain other districts, should perhaps make them view with equanimity the acceptance of lower than Government prices by other districts.

Production in the district continues at about 50 per cent. of capacity, stocks still being in evidence, while consumption, at least by the steel industry, continues to decrease and lake shipments do not amount to much in point of tonnage. There continues to be business, of small total tonnage, placed at various special cut prices, this not affecting the attitude of large producers or having any influence upon contract prices, which are well maintained, and with some operators refusing contracts for the full period to Apr. 1 next. We repeat last week's market quotations. Byproduct coal, largely nominal, mine-run, $2.35; high-grade gas coal, slack, $2.10@2.20; mine-run, $2.35; ¾-in., $2.50@2.60; 1¼-in., $2.60@2.70; steam, slack, $1.90@2; mine-run, $2@2.35; all net ton at mine, Pittsburgh district.

BUFFALO

Bituminous still slow. Anthracite moving fast. Some sizes scarce.

Bituminous—The market is still weak. Slack did not rally after it dropped off on the opening of the lake trade. Other grades hold pretty well, but it is only by efforts on the part of mine owners that any sort of profitable prices are maintained. This is partly because business is starting at a slow rate and partly because consumers refuse to accept the advice of the shippers and stock up against a sudden advance. It is the idea of the jobbers that consumption is still in excess of buying.

The Buffalo bituminous trade is so dependent on the Canadian movement that it is now especially slow, for Canada is not industrially as active as we are. Besides, the practice of shipping coal into Canada when it cannot be sold here always spoils that market when there is a surplus. The best to be said of the market is that the operators have held up production in a wonderful way against the small demand, thus showing that there is no excess profit to trade on.

Bituminous prices remain as before, with Allegheny Valley weaker than Pittsburgh, at $4.65 for Allegheny Valley sizes, $4.45 for Pittsburgh and No. 8 lump, $4.20 for same mine-run, and $3.80 for all slack, per net ton, f.o.b. Buffalo.

Anthracite—The demand has been heavy of late, on account of the advance in price this month. Some days the supply has given out, much as it used to during the shortage period. Some of the lake shippers have been unable to get any for loading vessels, but they are not anxious, for the upper-lake ports are not ordering any as yet. This is shown by the slackness of lake freights. They opened at 42½c. to the head of Lake Superior and 50c. to Milwaukee and South Chicago, but shippers have cut the rates so that a new adjustment is likely to take place soon.

Lake shipments for the week were 119,200 net tons, of which 32,800 tons cleared for Chicago, 29,700 tons for Duluth-Superior, 22,800 tons for Milwaukee, 10,500 tons for Marquette, 9500 tons for Sheboygan, 7500 tons for Fort William and 6400 tons for Hancock.

The general advance of anthracite has put up local prices 10c. a ton horizontally as follows.

	F.o.b. Cars Gross Ton	At Curb Net Ton
Grate	$8.65	$10.35
Egg	8.55	10.30
Stove	8.80	10.20
Chestnut	8.90	10.60
Pea	7.10	9.15
Buckwheat	5.80	7.85

With 25c. additional for loading to lake vessels.

CLEVELAND

Prices in the Cleveland coal market are rather spotty, with a leaning toward strength. Slack probably should be excepted, for No. 8 operators are virtually buried under surpluses. A great deal of business is being repressed because of uncertainty at Washington on the Peek-Hines controversy, and this is expected to come out once a decision is reached.

Bituminous—Operators believe considerbusiness that has been held back for weeks and months will be placed shortly, many steam-coal users having stated they would come into the market about May 15. The price disagreement at Washington will be settled soon, is the general belief, and a settlement will be followed by a marked stiffening in demand. Iron and steel and allied plants—the largest single class consumer of coal in northern Ohio—now are operating at from 30 to 40 per cent. of normal. The United States Steel Corporation is reported holding up shipments. But stabilization of prices will directly affect steam coal favorably, operators say, and the industry will buy again.

Meanwhile, slack coal is piling up at the mines in southern and eastern Ohio and the quotations have weakened accordingly. As low as $1.45 is reported for No. 8 slack by Cleveland consumers. On No. 6 slack, $1.60 is the lowest said to have been offered. For lake shipment, $1.60 has been quoted on No. 8 slack. No. 8¾-in. lump for the head of the lakes seems to have settled at $2.35 to $2.45, compared with $2.80 last season. Massillon lump prices have been advanced 15c., making the net ton delivered in Cleveland price $7.15 to $7.25. Pocahontas prices have remained unchanged, as have these of anthracite, but the tendency all the time is upward. Considerable domestic Pocahontas and anthracite is being taken.

Some mines in the No. 8 district are reported operating close to 100 per cent., while others, whose output is not going so largely to the lakes, are as low as one day a week. The railroads now are taking less fuel, reflecting poor business. Car supply everywhere is ample. Operators are unanimous in declaring bituminous coal will be scarcer and higher as the year wears on, and are campaigning actively to make sales, especially in the domestic trade.

Lake Trade—Chartering at Lake Erie ports is quite active, with the car dumpers handling all the way from 1600 to 1900 cars a day, probably averaging about 450,000 tons a week for the present. Both tonnage and cargoes are plentiful, and the feeling that it will be wise to crowd up as much coal as possible early in the season still persists.

Prices of coal per net ton delivered in Cleveland are:

Anthracite:	
Egg	$10.85 to 10.95
Chestnut	11.15 to 11.25
Grate	10.95
Stove	11.05 to 11.15
Pocahontas:	
Forked	8.50 to 8.75
Lump	7.78 to 8.01
Mine-run	7.20

Domestic bituminous:	
West Virginia splint	7.05 to 7.15
No. 8 Pittsburgh	6.10 to 6.35
Massillon lump	7.15 to 7.25
Steam coal:	
No. 6 slack	4.30 to 4.40
No. 8 slack	4.70 to 4.85
Youghiogheny	4.90 to 5.10
No. 8 ¾-in. lump	5.35 to 5.50
No. 6 mine-run	4.40 to 4.50
No. 8 mine-run	4.70 to 4.85

DETROIT

Buying demand continues light in the bituminous branch of the Detroit market. Prices are somewhat unsettled.

Bituminous—Only a small volume of business is being handled in the bituminous section of the Detroit market, according to jobbers, who also report that prices denote a rather unsettled condition. Consumers of steam coal are not buying freely, and their orders are described as few and scattering, covering only small tonnages. Many of the larger consumers are still deterred from action by the abnormal size of reserves. There seems a disposition on the part of a considerable number to remain out of the market until the present reserves have been largely cleared away, the purpose bing to get rid of as much as possible of the stock purchased last season, in which is much coal of low grade and unsatisfactory power.

Efforts to stimulate business by shading prices are imputed to some of the dealers who have been credited with being the most earnest advocates of maintaining price stability. Sales have not been increased materially by the lower prices, some of the jobbers say. Large consumers, they explain, would prefer to pay the prices fixed by the Fuel Administration, if by doing so they could feel assured that competitors would not be accorded a price reduction that would constitute an advantage.

On a long-ton basis, quotations at the mine are reported as being approximately $2.50 a ton on Hocking lump with West Virginia gas and splint lump 15c. higher and Pocahontas about $2.75. Mine-run from the Hocking and other leading Ohio districts is offered at $2, and from West Virginia at $2.25. Ohio slack ranges around $1.50, with the West Virginia product about 50c. higher. West Virginia splint and gas three-quarter-inch lump is quoted at $2.50.

Anthracite—Most of the leading retail dealers seem to be quite well supplied with anthracite. Though the movement has not been heavy, the unusual weather conditions have assisted in conserving the supply. Domestic consumers are being urged to buy next winter's fuel now.

Lake Trade—Despite the fact that there has apparently been only a moderately large movement of lake coal, preliminary reports indicate that shipments from Lake Erie ports to May 1, will exceed 1,000,000 tons, surpassing shipments of 860,797 tons in the similar period of 1918.

COLUMBUS

A slight improvement in the steam trade is reported in Ohio territory. Reserve stocks are being used up and some of the larger consumers are now in the market. Uncertainty as to price is still holding up contracting to a large degree.

The steam trade is showing slightly more activity than has been exhibited during the past few weeks. Buying on the part of certain manufacturing concerns is more active as reserve stocks have been used up in some instances. Contracting, however, is still held up because of uncertainty as to prices, and little is expected until the price question is settled.

Railroad business is still up in the air, so to speak. While some short-time agreements have been made, still the larger contracts are being held in abeyance until prices are adjusted. Large steam users are also waiting on the railroad fuel matter. Reserve stocks are still rather large, and consequently purchasers are biding their time. Rubber factories have large reserve stocks, and the same is true of many iron and steel plants. There is considerable steam tonnage being bought off the open market at reduced figures, but prices are not demoralized to any great extent.

The domestic trade is quiet, as little demand is reported except for the fancy grades. Pocahontas and West Virginia splints are moving well, and prices are generally above the last Government levels. Retail stocks are fairly good and most of the dealers are loath to increase them. Retail prices are fairly well maintained, and the larger dealers especially are holding firmly. The lake trade is slowly opening. May 1 was the date set for the official opening of navigation, and some vessels were loaded at that date ready for movement to the Northwest. But dockmen are slow in making contracts because of price uncertainty. The lake trade is not expected to be under full sway before June 1. A large tonnage is being carried over on the upper lake docks.

CINCINNATI

Steady improvement evident in coal market conditions.

Generally speaking, the coal situation in Cincinnati has shown a steady improvement, and the business transacted during the past week augurs well for the immediate future. The large coal dealers have expressed themselves as being satisfied with the existing conditions, and the continued flow of inquiries is taken as a sign that the consumer is no longer waiting for prices to drop, but is contemplating the placing of orders. The large industrial firms have shown a willingness to make contracts for steam grades, which is in itself a good omen as this kind of buying has been quiet here recently. The demand for domestic grades is comparatively steady. Prices are remaining firm with no immediate prospects of serious fluctuation.

LOUISVILLE

Markets stronger, with good demand. Many producers raising prices on domestic, and feeling that they have sold too much coal at less than it is worth.

There has been a strong demand for better grades of domestic coal during the past few days, and many of the operators of eastern Kentucky who were quoting prices of $2.85 are now quoting a minimum of $3. Prices given out to jobbers and retailers a few weeks ago, and for April, May and June delivery, were based on regular monthly shipments of at least ten cars. Buyers in many instances were uncertain over this point, and figured that prices were set for the three months.

The demand for mine-run and general lines of steam coal has been better. Railroads have been buying freely, but have been unable to secure much good engine coal on contract at much less than $2.35 per ton for eastern Kentucky. Industrial consumption is picking up as even large stockers are running low. Byproducts plants are not buying much, as they loaded up strongly some months ago, are still fairly well stocked and not operating at capacity. The demand for the steel and iron industries is not strong.

Retailers are buying a fair volume of coal for stocking purposes, and report a slight improvement in local demand. However, not much stocking is expected on the part of the domestic consumer until late in May.

Egg sizes are back to prewar differentials of about 25 per cent. under block coal, and that is where the grade should be according to many operators, who never figured that egg should sell for block prices. General quotations, short tons, are as follows:

	Eastern Kentucky	Western Kentucky
Block	$3.00@$3.25	$2.60
Egg	2.60@ 2.85	2.60
Run-of-mine	2.40	2.35
Nut and slack	2 00	2.05

The fact that the better grades of eastern Kentucky and West Virginia, as well as smokeless coal, can be secured this year during the early spring and summer is expected to encourage buying on the part of better grade consumers who held off last year in hopes of eventually being able to secure high grades.

Enough river coal is arriving to take care of the river handlers, there being only three or four companies along the river who are making any effort to handle barge coal. These concerns are now securing very fair shipments.

BIRMINGHAM

Market conditions without change, steam trade being dull. Domestic demand keeps pace with the output. Commercial production on about the same basis as past few weeks. Mines of furnace companies either closed down entirely or operated on about 50 per cent. schedule.

As far as sales are concerned, there is no improvement in the local market over a week ago, though basic conditions of the trade are considered as stable and more promising. Consumers are rapidly using up their reserve supply and will be obliged to buy coal in the near future to supply the needs of industry. The output of steam coal is being absorbed daily and there is no accumulation, while prices are being maintained firmly on Government schedule in effect Jan. 31.

Domestic coal is moving as fast as it is mined, and there is demand for more than is to be had at this time. Yards are stocking slowly, not being able to secure the tonnage that they desire on account of the restricted amount of domestic coal coming from the steam-domestic operations.

Collieries throughout the district, outside of domestic mines and those employing convict labor, are running on about half time. Some of the largest mines of the furnace companies have been closed down and will remain idle pending improvement in the iron market.

Coke

CONNELLSVILLE

Spot furnace coke market stiffer. Adjustment values approximately unchanged. Production continues to decline.

The spot furnace coke market is distinctly stiffer. As to the general market, this is of little direct consequence, for the spot market has been a narrow affair for weeks, represented by small tonnage that a few operators had to dispose of, while there was scarcely any demand from furnaces as the furnaces were well supplied by contract deliveries. The operators have been endeavoring to adjust production precisely to requirements so that there would not be any spot coke to offer, but furnaces have been blowing out at such a pace, and so suddenly, that this has been difficult. Now the operators seem to be catching up. Their production has certainly decreased at a rapid rate. One week ago and two weeks ago there was spot furnace coke to be had at $3.60, and it was thought $3.50 might possibly be done, while the best grade would bring only $3.75. In the past few days the cheapest coke available has been $3.65, and $3.75 has been paid in several instances.

Adjustments for May shipments on contract are not favorably affected by the stiffening in the spot market, except that they reduce the ammunition of furnaces seeking a lower price than was arranged for April deliveries. One operator refused to go below $4, as desired by the furnace, and the contract has been canceled. Adjustments have probably been made, or will be made, at $4, with perhaps an occasional adjustment at a slightly higher figure.

Foundry coke is in about the same position as formerly, there being a fair demand, but in tonnages much smaller than the foundries involved usually take. The market may be quoted at $3.65@3.75 for spot furnace, $4@4.25 on contract adjustments for furnace and $4.25@6 for foundry, depending on brand, per net ton at ovens.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended Apr. 26 at 135,360 tons, a decrease of 13,465 tons.

Buffalo—The demand continues light, with prices not always uniform. Quotations run from $7.25 to $7.60 for 72-hour foundry, $6.60 to $7 for 48-hour furnace, and $6 to $6.10 for off grades. Breeze and other reject coke are still unsalable. The lake movement of iron ore sets in slowly. As a rule the furnaces are not receiving any, for the regular sales have not been made yet. A little has come in on carrying contracts that held over from last season. The lake fleet depends in the main on grain for down cargoes, hoping for ore on the next trip.

Middle Western

GENERAL REVIEW

Coal market on the mend, and mining conditions showing great improvement. Railroad situation still affects Middle West.

The coal situation throughout the Middle West continues to show a slight improvement over last week. While this improvement is small, as usual, it is encouraging to note that within the last six weeks the market has been on the mend, rather than on the decline.

Reports from the Franklin and Harrisburg districts of Illinois are especially gratifying, both from the standpoint of improvement on current shipments and on contract. The buying public is showing an increased tendency to cover their coal requirements by contract, although unfortunately some of these contracts do not call for shipment until later in the season. No matter which way you look at it, however, a contract means that a certain

amount of coal is taken from the market for the year, and if the number of contracts is large enough, their influence is bound to be felt sooner or later.

Roughly speaking, the mines in Southern Illinois showed a decided improvement. Next came the mines in the Central district, which just about held their own. The scattered coal-producing properties throughout the rest of the state showed a little decrease in the tonnage produced and sold, but this is only natural, considering the dull times we are now experiencing. The situation in Indiana is not quite so good as that in Illinois. Even the mines in the Indiana Fourth Vein district slipped back a little rather than improved. This decrease in tonnage in the Indiana fields is so small that it is practically negligible.

The railroad situation continues dull in the extreme. The only reports available show that some of the roads bought little coal from mines in the Springfield district. No railroad coal was sold in Indiana last week. While the mines in the Middle West are idle, the gentlemen in charge of the purchase of coal for the railroads down at Washington continue to dilly-dally and delay matters to an extent which is proving decidedly disadvantageous to the coal industry in the Middle West. There is no denying the fact that there would be a tremendous improvement, both in the coal market and in operating conditions, if the proper authorities at Washington would make up their minds to tackle the railroad fuel question in the right way and settle it at an early date. In the meantime, labor is growing restive under the delays, and some operations report losing a large number of their men to other industries.

The bulletin of the National Coal Association reports that there was an increase for the week of 1468 cars for the producing fields of Indiana and Illinois. Inasmuch as the number of cars produced the week before last was 6668, this increase of practically 1500 cars is especially gratifying. The operators appear to be confirmed optimists, and they are looking forward to a time, within the next four to six weeks, when conditions will be much better than they are now.

CHICAGO

Steam market improves while domestic situation is unchanged. Pocahontas coal brings high prices.

The Chicago steam market has improved a little, as several sizable sales on the current market have been reported. Furthermore, the tendency throughout the country to contract for coal has been felt in Chicago, and a number of contracts closed have been for Chicago plants. Coal piles are getting pretty low, and this is bringing a large number of purchasing agents back into the market once more.

The domestic situation for the city continues unchanged, with a big demand for high-grade Eastern coal, and but little demand for coals produced in this territory. It is reported that Pocahontas and New River lump or egg have been sold as high as $4.25 to $4.50 per ton, f.o.b. mines. The reasons for this condition are: First—the retail dealers of Chicago feel that if they do not buy their Pocahontas coal now, they won't be able to buy it later on, on account of the export plans of the Administration. Second—the public have not taken at all kindly to the increased prices on anthracite, and therefore there is a very strong demand for high-grade substitutes, such as Pocahontas. Third—the West Virginia operators are having a hard time placing their steam sizes; in fact, their steam sizes have to be sacrificed. For this reason they are trying to break even by placing abnormally high prices on their domestic sizes.

Prices are as follows:

	F.o.b. Mines, Per Ton	Rate to Chicago
Southern Illinois Franklin, Saline and Williamson Counties, Etc.		
Prepared sizes	$2.55 to $2.75	$1.55
Mine-run	2.35 to 2.50	1.55
Screenings	1.85 to 2.20	1.55
Central Illinois—Springfield District		
Prepared sizes	$2.55 to $2.75	$1.32
Mine-run	2.35	1.32
Screenings	2.05	1.32
Northern Illinois		
Prepared sizes	$3.25	1.24
Mine-run	3.00	1.24
Screenings	2.75	1.24
INDIANA		
Clinton Fourth Vein District		
Prepared sizes	$2.65 to $2.75	1.27
Mine-run	2.35 to 2.45	1.27
Screenings	2.05 to 2.25	1.27
Knox County Field		
Prepared sizes	2.65 to 2.75	1.37
Mine-run	2.35 to 2.45	1.37
Screenings	2.05 to 2.25	1.37
West Virginia Splint		
Prepared sizes	2.50 to 2.75	2.60
Mine-run	2.25 to 2.50	2.60
New River and Pocahontas		
Prepared sizes	4.25 to 4.50	2.60
Mine-run	2.75 to 3.25	2.60
Hazard and Harlan, Ky.		
Prepared sizes	3.00 to 3.50	2.45
Mine-run	2.55 to 2.75	2.45
Nut, pea and slack	1.80 to 2.30	2.45
Cannel lump	2.75 to 3.50	2.45
Smithing coal	3.00 to 3.25	2.60

MILWAUKEE

Promulgation of the spring price schedule stimulates the coal market. Coal cargoes arriving daily by lake.

The coal market, which has been quiet pending the promulgation of the spring schedule of prices, is now on a better basis, and a steady increase in business is looked for. The new schedule, which became effective May 1, cuts anthracite grades 20c. per ton, with the exception of buckwheat, which was reduced 85c. The reductions in eastern bituminous are much heavier. Illinois and Indiana coals remain unchanged. Dealers are urging consumers to stock up early at present prices, as coal and service are at bottom figures for the season. It is expected that prices will be stiffened on hard coal as the season advances. The custom in the past has been to add 10c. per ton to anthracite each month until September, in order to stimulate ordering.

Milwaukee got an early start on coal supplies by lake this year. Eighteen cargoes were received during the month of April, the aggregate receipts being 59,535 tons of anthracite and 92,652 tons of soft coal. Last year no coal cargoes were received in April. The first day of May brought three cargoes aggregating 7300 tons of anthracite and 9600 tons of soft coal.

Following are the retail prices of coal at Milwaukee which became effective on the first of May:

For Domestic Use

Anthracite—Chestnut, $12.30; stove, $12.20; egg, $12; pea, $10.80; buckwheat, $9.75.

Bituminous—West Virginia splint, screened, $7.25; Hi-Heat, $7.25; Hocking lump, egg and nut, $7; Pittsburgh, screened, $7; Pocahontas, mine-run, $7.75; Pocahontas, egg and nut, $9.75; Cheerful Chunks (Kentucky for grates), $7.75; Smithing, $8.10.

Coke—Range, egg and nut, $11; pea, $9.75.

An extra charge of 50c. per ton if coal is carried in, and an extra charge of 25c. per ton on all deliveries in less than ton lots. No extra charge for carrying in coke, but an extra charge of 25c. per ton on orders of less than one ton.

Steam Coal

Youghiogheny—Screened, $6.10; pile run, $5.85; screenings, $5.25. Pittsburgh—Screened, $6; pile run, $5.60; screenings, $5.25. Hocking Lump—Screened, $6; pile run, $5.60; screenings, $5. West Virginia Splint—Screened, $6.25; pile run, $5.85; screenings, $5.25. Kentucky Lump—Screened, $6.75; pile run, $6.35; screenings, $5.25. Pocahontas—Mine run, $7; screenings, $5.50; Kanawha Gas—Mine-run, $5.75. Smithing, $7.10.

Illinois and Indiana—Screened, $6.50; pile run, $6.25; screenings, $6; smithing, $7.68.

ST. LOUIS

An inactive market, with everything lagging. Some few contracts being let on local business at a price below cost of production.

The local situation is not encouraging, for the reason that local wagon-load delivery contracts in St. Louis are going far below cost of production. In spite of the efforts made by the United Mine Workers to keep their operators from selling coal below cost, the fact remains that it continues to a greater extent now than at any time since the Fuel Administration removed restrictions.

The market has shown a tendency to strengthen some on screenings, but on other sizes, if anything, there has been a breaking away from the prices that were maintained some time ago. There is a little railroad tonnage moving out of these fields, but it is so slight that it makes little impression on the field as a whole. The few contracts that are being made other than railroad are light and are not taking much tonnage at this time.

In the Mt. Olive and Staunton fields prices are pretty well maintained, and while work is not plentiful the mines for the most part are getting a couple of days a week. This coal continues to move north and west and in fairly good tonnage, everything considered.

In the Carterville field of Williamson and Franklin Counties there has been a let-up in the amount of business offered, with the result that working time continues to decrease, and practically every mine in the entire district now producing commercial coal is on short time. As in other fields, screenings are in good demand, as well as the smaller sizes of nut. The railroad tonnage from this field is somewhat light, but even at that it is heavy enough to make an impression in the tonnage of certain operations, as well as to keep a large number of miners satisfied as to time.

One of the things noticeable at the present time is the failure of business to come from the south as heretofore. This coal seems to have lost out in a large section of the south to which it formerly went at this season of the year in heavy volume. This is occasioned by the fact that the larger part of this territory has been neglected during the high price period in the past year or two, and also the inroads made by the West Kentucky and Alabama coal will be hard to overcome.

There is at the present time a light tonnage of Carterville and anthracite being put into storage, but it is not noticeable. It will, however, continue to grow from now on. The same may be said of coke, both byproduct and gas.

There is no smokeless coming in and no demand for it and the same applies to Arkansas.

Denver	.99	Pacific Coast (all rail)	1.25*
Kansas City	.59		

Note—Add 3% transportation tax. Minimum carload, 80,000 lb.

COAL AGE

Volume 15 New York, May 15, 1919 Number 20

The Day of New Ideals

By Floyd W. Parsons

OLSHEVISM will not prevail in the world for the reason that it will not be successful for those who are advocating it. What a man gets by force will eventually be taken away from him by someone else who is stronger. The bitter opponent of all mobs of industrial shirkers that become active in the United States from time to time will not be the capitalist, but the American workman himself. The other day in Washington I was talking to a great labor leader, and he was emphatic in the statement that "an autocracy of labor is as bad as an autocracy of capital."

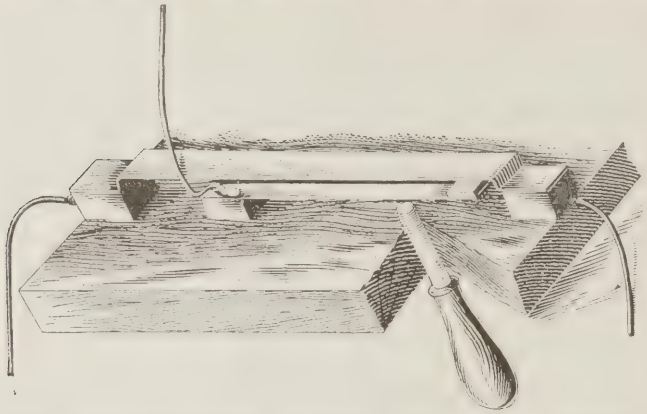
The average workingman in this country is the most intelligent employee in the world. He is fully aware that our social system is not perfect, but he knows that such alterations in our laws as are demanded by the changing times can be brought about by methods that do not include rapine, bloodshed and incendiarism. He also has learned that in this great Nation a majority of those who have reached prosperity began life in humble circumstances. Among us there are a few so-called "lucky" men who have achieved wealth without labor, but as a general rule those among us who succeed do so through intense application and never-ceasing industry.

The lessons of the war plainly indicate the commencement of a new era throughout the world. Although we are fortunate to live in a country where the new order of things will be inaugurated in a sane and peaceful fashion, this does not mean that the parties to industry can act with indifference toward the necessities of the times. Labor in America has proved to capital that it stands as a barrier between destructive radicalism and a rule of law. Employers who have not seen this and do not appreciate the fact will lose out in the coming days, because they still stand as representatives of a system in business that can no longer succeed.

There is no doubt that betterment work, profit-sharing, bonus payments and stock ownership are splendid ways to hold the interest of the worker and to share the fruits of business with him. But all of these plans fail to give the employee the thing he desires most, and that is an opportunity to fully express his individuality. No industrial scheme will ever operate with complete success unless it creates in the workman the same sort of interest that he would have if working for himself. Old ideals are no more, and old conditions will no longer be accepted without question.

The real labor problems of the future will not be so concerned about wages and hours as has been the case in the past. Large labor turnovers will be remedied with something besides dollars. High costs will more often be properly attributed to low production, and the latter will be found to result from an uninterested working force. It has been demonstrated time and again that the output of a plant can often be increased 50 per cent. by some simple adjustment that removes the cause of general unhappiness on the part of a company's employees.

On the other hand, there should be no confusing of charity and business. No self-respecting man desires to have his life ordered for him. Those corporations that will be most successful in the future will be the ones where wise managements have imbued the men with a spirit somewhat akin to the feeling that, in the past, nourished only the owners of many establishments.



The cause of the failure of radicalism in America is identical with the cause of the failure of nineteenth-century conservatism. In both cases the workman is deprived of incentive by a system that holds forth no reward and thus kills individual initiative. Of course, any employer is free to fight the present desire of workmen for recognition, but the farsighted boss today will secure for his business all the brains and energy of his men by hitching up with them and pulling in double harness. Such managements are the only ones that can survive.

IDEAS AND SUGGESTIONS

Homemade Signal-Light Switch

BY JOSEPH POWER
Ziegler, Ill.

The illustration shows a switch for signal lights that may be made readily in the average mine shop. The drawing is practically self-explanatory and needs little comment. In operation the plug is pushed in until contact is made with the copper sheet, breaking contact with the line to the red light. This extinguishes the

EASILY CONSTRUCTED SWITCH FOR SIGNAL LIGHTS

red light and lights the green one. A release or withdrawal of the wooden plug extinguishes the green light and relights the red light.

This device may be advantageously built on sections of 1-in. plank, when and in the quantity needed. With such planks a switch of this kind can usually be built in from ½ to ¾ hour each. The chief materials are copper sheets and nails.

Reinforced Concrete Used as Props in English Coal Mines

Shortage of timber in England is largely responsible for the recent introduction of reinforced-concrete props in the coal mines of that country. But for this shortage it might have been many years before this form of prop would have been regarded as established, and this despite the fact that reinforced concrete has been employed for most other forms of construction and has been extensively adopted by the collieries. The scanty use which hitherto has been made of concrete props is not due to apathy on the part of the colliery manager, says the *Engineering World,* nor yet to his failure to appreciate their possibilities. In the first place there has been a disinclination to use anything other than timber on account of the extra weight involved in handling concrete props. Then there is the question of cost, which in the pre-war days was wholly unfavorable to concrete as compared with timber. That, however, is merely a question of initial outlay and can in no sense be regarded as a fair comparison, which would only be possible by considering the maintenance costs of a given length of roadway of concrete and timber props for a certain length of time.

All other conditions being equal, there is little reason to doubt that the concrete prop would prove the better investment, especially in districts tending to bring about either dry or wet rot. Also with concrete props a better roadway can be maintained than would be the case with timber, which has an important bearing upon the matter of ventilation. An objection raised against the concrete prop is that, unlike timber, it gives no warning but collapses suddenly when the breaking strain is reached; this, however, is disputed in the event a proper reinforcing and suitable concrete is used.

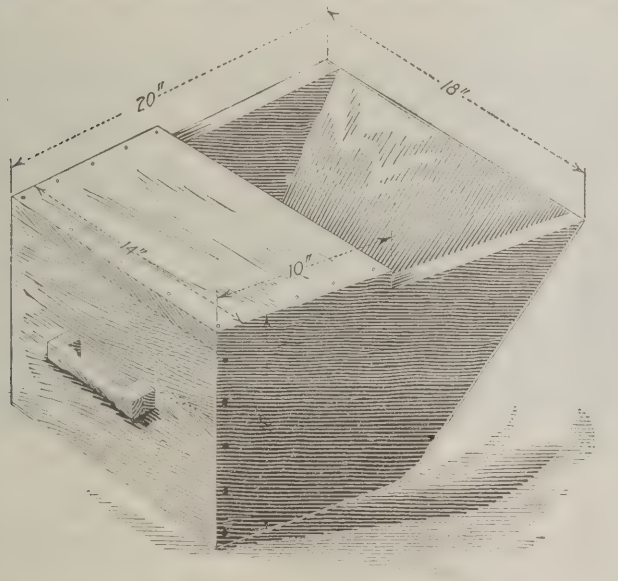
Up to this time practically all the concrete props used in England have been made at the collieries where they were installed; in some instances they have been made remarkably well considering the available facilities for their construction. In some cases, however, the reinforcement has been of the makeshift order; and owing to the method used in filling the molds, there has not been the necessary intimate relation between the concrete and the reinforcement which is an indispensable condition of success. To counteract the resulting weakness of improperly designed props, they are frequently made far heavier than necessary. As a result of numerous tests on various types of concrete props, the design has been much improved and props are now being manufactured in standard sizes and placed on the market.

New Method of Gas Detection

BY E. P. BRENNAN
Thomas, W. Va.

In mines where the ordinary flame type of safety lamp is the only means used for the detection of explosive gas, many dangerous conditions have often existed and many unaccountable accidents occurred. Especially is this so in open-light mines where the failure to detect gas is sure to lead to disaster. The firebosses and other mine officials are unable to detect deposits of methane when these are in thin layers near the roof. Very often the inability to detect gas is not due to the incompetency of firebosses or other officials, but to the construction of the lamp used in testing.

In nearly all ordinary safety lamps approved for mine use, the air containing the oxygen necessary for combustion enters either below the flame or over the glass cylinder, and so a little above the flame; and as this is at a point varying from 6 to 10 in. below the top of the lamp, there is always a possibility of thin layers of gas remaining undetected.



I have overcome this difficulty by using an ordinary bulb syringe, which is a small, soft-rubber ball with a hard-rubber tube attached. With this syringe an air sample can be secured from any desired place even though that place may be entirely inaccessible to the safety lamp. The sample is then forced slowly onto the flame of the lamp through the proper channels, and methane, if present, is detected in the usual way.

No one should experience any trouble in securing and testing a sample. The operation is very simple, as will be seen from the following description: Squeeze the soft-rubber ball tightly with one hand. This forces out the air. Then hold the nozzle of the syringe at the place where the test is to be made. Release the pressure of the hand and allow the ball to resume its normal shape. This draws in a sample of the mine air through the hard-rubber tube. Hold the tube in a downward position to retain the sample in the ball, then place the end of the tube under the intake ring of the lamp and force the sample onto the flame by squeezing the ball.—*Our Own People, a monthly publication of the Davis Coal and Coke Co.*

Water Scuttle or Bucket

By W. H. Luxton
Linton, Ind.

Efficient methods of performing any kind of work or labor ought to be encouraged so far as possible. The accompanying illustration shows a water scuttle or bucket that is so constructed as to gather thin sheets of water and do away with the present method of bailing it—namely, lifting it into a powder keg with an old coal shovel and then dumping the keg's contents

WATER SCUTTLE THAT DOES AWAY WITH THE NECESSITY OF BAILING

into a water box. The latter is a costly method as it is decidedly slow.

The sides, part of the top and the rear end of the scoop, to which the handle is attached, are made of 1 x 10-in. lumber. The bottom is of thin sheet iron or block tin, with holes punched as shown for nailing purposes. The scoop is of convenient shape to scoop up shallow water. Both hands get a suitable hold, similar to that in which a miner would utilize a shovel. One hand takes hold of the cross-piece, or cover, while the other grasps the handle.

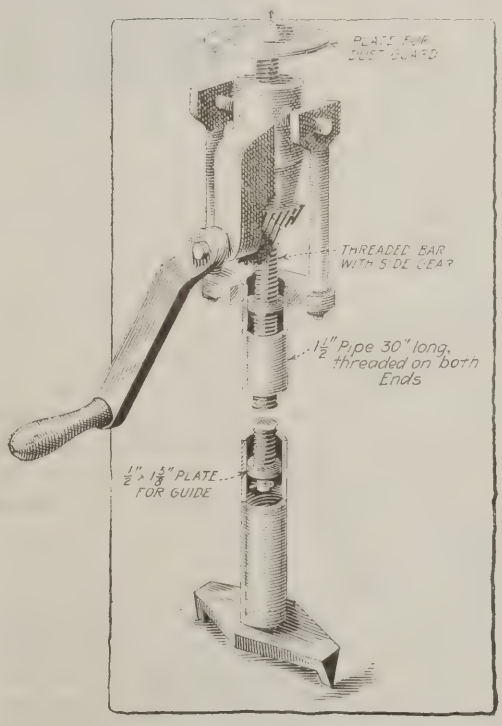
Since employees are liable to cut their hands when using powder kegs, and such cuts sometimes prove serious, safety of operation ought to be an incentive to the use of the scuttle here described. It can be constructed readily in mine shops or elsewhere at small expense.

Handy Spike Carrier

By S. D. Hainley
Osceola Mills, Penn.

In my travels from mine to mine I have noticed the different receptacles that tracklayers and daymen use for carrying spikes, nails and similar articles. Most of them employ an old dinner pail, kettle or something of the sort that can be picked up around town.

The best receptacle of this kind that I have yet seen, considering cost, durability, convenience and safety, was



SIMPLIFIES CARRYING OF SPIKES

one made out of a powder can (25-lb. keg), cut in two through the middle, with the rough edge belled down on the inside. Thus, in reaching for a spike or nail, there will be no danger of cutting the hand. Two holes are then punched—a 20d nail will do for a punch—on opposite sides, for a bail, which can be made out of an old bond or almost anything that makes the completed pail easy to handle.

Portable Mine Drill

By W. A. Jones
Sturgis, Ky.

A roof drill that has been found useful and satisfactory is shown below. The machine is simple and light, yet is strong in construction. The drill may be

SIMPLE HOMEMADE MINE DRILL

easily and quickly transported about the mine and set up rapidly where needed. Any ordinary mine blacksmith ought to be able to build this drill.

The Future of Peat as a Fuel—I

By J. B. C. Kershaw
Colwyn Bay, North Wales

SYNOPSIS—*Peat is probably more widely distributed throughout the world than were the original beds of coal-forming materials. Many attempts have been made to utilize this low-grade fuel. Although after the sods, or "turves," are air-dried they are extensively employed in certain localities for domestic purposes, the more ambitious attempts at the use of peat for power generation employ a briquetting process of some sort.*

NEXT to coal, peat is the most widely distributed naturally occurring solid fuel. In fact, if one considers only the area covered by the peat deposits of the world, without relation to their depth or thickness, it is probably true that the deposits of peat now occupy a larger area of the earth's surface than was occupied by the lower-lying coal measures in the earlier stages of geological history. The figures given hereafter enable one to form some idea of the enormous extent of the area covered by the peat bogs in all countries situated in the northern temperate zone. The occurrence of peat in temperate regions is explained only by the fact that the plant growths that produce peat require a moist but cool atmosphere and habitat for their development. This is never found nearer to the equator than 45 deg., nor does it occur within the frigid zone. Peat is found in abundance in the United States, Great Britain and Ireland, Denmark, France, Germany, Hanover, Holland, Hungary, Italy, Oldenburg, Russia, Bavaria and Sweden. As regards area and extent, the peat bogs of what were up to a few years ago the "crown lands" of Russia, are reported to contain 100,000,000 cu.ft. of excellent peat. The Swedish bogs are estimated to represent 3,000,000,000 tons, while the swamp regions of Virginia cover nearly 1000 square miles and have an average depth of 15 ft. In Germany the peat bogs cover 11,580 square miles, and in Ireland one-tenth of the surface of the whole country. The depth of the Irish bogs varies from 16 to 23 ft., but in certain cases this depth is much exceeded and some are known to have a depth of 50 ft. Finally, in the United Kingdom, which is liberally provided with coal measures, there are, according to Perkin, 6,000,000 acres of peat bog, with an average depth of 12 feet.

All the nations of the world, therefore, whose industrial activity and prosperity in the past have been based on the development of their deposits of coal, are well provided with this alternative source of heat and power.

The question of the best methods of utilizing their resources of peat is one of the highest importance for the leading manufacturing countries of the world. As their reserves of coal become exhausted, and the cost of working them increases, it will be necessary to fall back upon peat in order to be able to compete in the world's markets with countries such as Switzerland, Norway and Sweden, which possess immense water-powers capable of cheap development for industrial purposes.

This change from coal to peat is already occurring in certain European countries where coal is not plentiful or is of poor quality. And the change, no doubt, will be accelerated by the results of the recent war, which has already doubled the cost of coal mining, and consequently the price of coal, in nearly all the countries of the world.

Peat is a mass of decaying vegetable matter which under suitable natural conditions and with the lapse of time might be converted into a form of coal. The peat bogs to which reference has been made in the foregoing paragraphs may therefore be regarded as composed of a partially formed solid fuel that comes under the classification of "low-grade" fuel, owing to its high percentage of moisture.

FIG. 1. CUTTING PEAT FROM A LARGE BOG IN DUMFRIESSHIRE, SCOTLAND

If heat and great pressure were applied to this mass of decaying vegetable matter and the water were eliminated, a residue would probably remain that would possess many of the characteristics of coal. This conversion of vegetable remains into peat occurs only in swampy districts, because the water shuts off the decaying plant from the action of oxygen or air, and the decomposition that occurs is due, not to oxidation, but to internal changes which may be represented by the following chemical equation:

$$6C_6H_{10}O_5 = 7CO_2 + 3CH_4 + 14H_2O + C_{26}H_{20}O_2$$

Cellulose thus yields carbonic-acid gas, marsh gas, water and peat. The molecule of peat is therefore more complex in structure than that of cellulose. It is represented by 26 atoms of carbon with 20 of hydrogen and 2 of oxygen. Its molecular weight consequently is 364.

The moisture in peat is therefore largely due to the water evolved as a result of the chemical changes accompanying its formation. Peat fresh from the bog often contains from 80 to 90 per cent. of moisture.

FIG. 2. METHOD OF DRYING PEAT IN SCOTLAND

By air-drying, with prolonged exposure to wind and sun, this moisture content can be reduced to 20 per cent. Below this limit it is difficult if not impossible to pass by means of natural agencies, and this fact explains why peat has never come into wide use for industrial purposes, where the supplies of other forms of fuel have been both plentiful and cheap.

The high percentage of volatile matter in peat is another hindrance to its use for industrial purposes, since the heat produced by its combustion can only be economically utilized in special forms of furnaces. The low percentage of ash and absence of sulphur, on the other hand, are characteristics of the fuel which count in its favor. The disadvantages arising from the high percentage of moisture and volatile matter, however, have been largely surmounted in the latest methods of using peat for power purposes.

The following are approximate analyses made in my own laboratory, on air-dried English, Irish and Scotch peat:

	English Peat		Irish Peat		Scotch Peat	
Moisture	20.3		21.6		26.2	
Coke	27.9	Ash 1.0, Fixed carbon 26.9	21.8	Ash 2.3, Fixed carbon 19.5	24.6	Ash 2.1, Fixed carbon 22.5
Volatile	51.8		56.6		49.2	
	100.0		100.0		100.0	

The calorific value of air-dried peat varies considerably, but the average may be fixed at 7500 B.t.u. Peat briquets dried by natural agencies may be considered as possessing half the heat content of good coal.

Peat Briquets

The earliest method of peat utilization was that of slicing the brown and black peat of the bog into small oblong blocks, called "turves," and allowing these to dry in the sun and air. The turves, which in Ireland are cut 24 in. long by 6 or 7 in. square, shrink considerably on drying, and are only about half this size when ready for use. Much of the domestic fuel burned in the villages and towns of Ireland today is peat won from the bogs by hand labor and dried in this way. Figs. 1 and 2 show the system in use in Dumfriesshire, in Scotland.

Modern methods of briquetting peat, however, are based upon the use of machinery, both for cutting the peat, squeezing out the excessive moisture, and for molding the material into briquets afterward. The aim has always been to reduce the hand labor required for these operations to the lowest possible point.

Some details will now be given of the more notable and successful installations of this kind, commencing with those in use abroad, since it is in Germany and Russia that the greatest progress has been made in utilizing the peat and bogland resources of the European continent.

Germany.—The manufacture of peat fuel briquets, even before the war, was a flourishing industry in Germany, and there is no reason to believe that the industry has suffered any setback during the period of hostilities, since the scarcity of coal and rising price in all countries have favored the production of the cheaper low-grade fuel.

The peat, in the majority of the German installations, is won from the bog by portable centrifugal pump dredgers, which first cut and pulp the peat by means of rotary cutters, and then transport the pulped mass (which contains 15 times its own volume of water), to the factory, where the briquet-making machinery is installed. Here the pulp is first passed through a centrifugal machine to extract the greater part of the water, and is then transferred to a cylinder press, which operates on the principle of a paper-making machine and delivers the peat in the form of a thin sheet to the drying cylinders.

The moisture in this way is reduced to between 15 and 30 per cent. and the peat, in the form of a moist hot powder, is then fed into the briquetting machine. Here it is subjected to a pressure of 30,000 lb., and is molded into the form and shape desired for the finished briquet fuel. No binding agent is required, since the bituminous matter contained in the raw peat suffices in the majority of cases, under the combined influence of pressure and heat, to produce a clean and hard briquet, in which the percentage of moisture is between 11 and 15 per cent. and the ash from 9 to 12 per cent. The calorific value of these machine-made briquets is said to be about seven-eighths that of ordinary coal. The cost of manufacture, in Germany, before the war, was from $1.25 to $1.75 per ton. A plant to produce 50 tons per day was estimated to cost $80,000.

Peat briquets are largely used for domestic heating purposes in Germany, since they are practically smokeless. In order to prove, however, that the generation of power is quite practicable with this form of fuel, some details will be given of the electric power-generating station situated on the Wiesmoor peat bog in East Friesland, North Germany, which is run entirely with peat won from this extensive tract of bogland.

Fig. 4 shows the position of the bog, which is shaded, and the 150-mile district over which the current is distributed. The original power station marked *A* in the plan was erected in 1909, and was designed to generate 3600 hp. It has been twice enlarged and now provides considerably over 6000 hp. to the docks and harbor at Emden, and to the electric tramways that run into Wil-

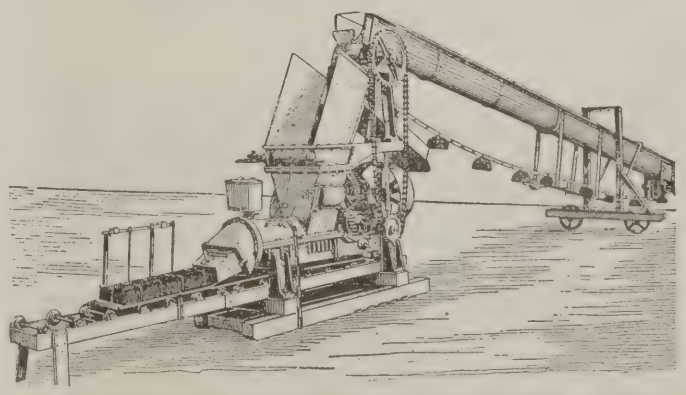


FIG. 3. GERMAN MACHINE THAT MAKES PEAT BRIQUETS

helmshaven and Oldenberg from the surrounding villages. The Ems-Yade canal is also operated with electric power, derived from the Wiesmoor generating station.

Fig. 5 shows the main transmission lines, with their length marked in kilometers. The power house, after the first enlargement, was equipped with four water-tube boilers and superheaters, and with three turbo-generators each of 1250-kw. capacity, delivering three-phase current at 6000 volts. This potential is raised in a separate transformer house to 20,000 volts for transmission purposes.

A portion of the electric power is utilized for operating the electric dredging machines, which form one of the chief features of this installation. The dredgers used at Wiesmoor were designed and built by an Oldenberg firm of engineers and are mounted upon wheels, so that they can be run on timbers or on rails along the edge of the bog. The dredgers are of the chain-bucket type, the chain being driven by an electric motor placed at the head of the bucket frame. A second motor, placed to the left, causes the whole bucket frame to travel in a horizontal direction, backward and forward, through a space of about 13 ft. The wet turf, containing 90 per cent. of water, is emptied from the buckets into a trough and is carried from this by means of a belt conveyor to an electrically operated press. It issues from this press in the form of a uniformly thick pulp, and is then, with the aid of another electrically operated conveyor, carried to the cleared and drained portion of the bogland for drying, where it is delivered in the form of a thick carpet.

In addition to the large dredgers there are many smaller turf-pulping machines at work on the Wiesmoor.

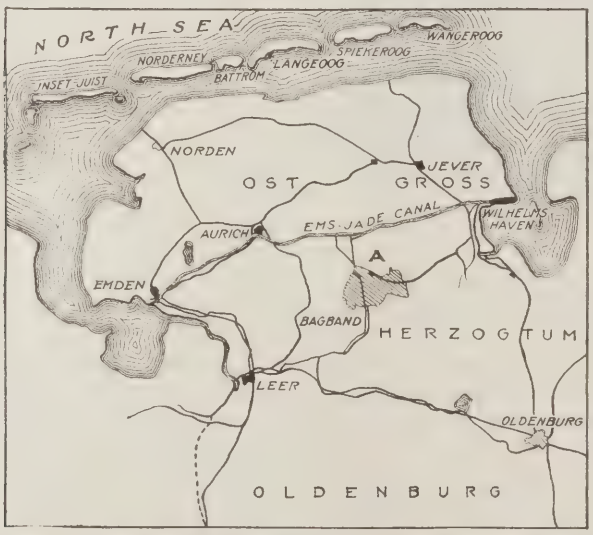

FIG. 4. WIESMOOR PEAT BOG, EAST FRIESLAND, NORTH GERMANY

Those machines are fed by hand and consist of an electrically operated bucket conveyor and a pulping and molding press that tears apart the peat fibers and then pulps them. The peat pulp issues from the press in the form of a continuous thick belt, and a workman standing by the delivery chute cuts the peat into strips. These machines are much smaller than the others, and a 12-hp. electric motor is sufficient for operating them. According to the guarantee of the manufacturing firm, one machine in a 10-hour day can produce 60,000 to 80,000 turf sods or briquets.

Fig. 3 shows a machine of this type at work and Fig. 6 a German design of drying installation with use of artificial heat.

The size of the blocks of half-dried peat when first cut into is 4 x 5 x 13 in. As soon as a dry crust has formed upon them so that they can be handled they are stacked in small heaps, where they are left exposed to the sun and air until the moisture content has been reduced to 25 or 30 per cent. and the blocks have shrunk in size to 2 x 2 x 10 in. They are then loaded in cars, which are drawn along a narrow-gage railway by a gasoline locomotive to the power house. In the summer months the output of dried peat from the dredgers and drying grounds exceeds that of the requirements of the generating station, and the surplus dried peat is therefore built up in large stacks in the open, or is stored

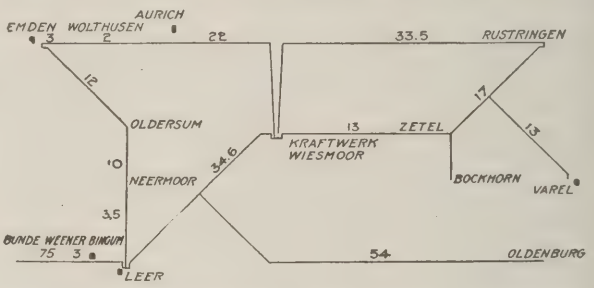

FIG. 5. TRANSMISSION LINES FROM WIESMOOR GENERATING STATION

in covered sheds. When once dried and hard the peat blocks do not readily take up additional water.

The combined dredging and briquet-molding equipment installed on the Wiesmoor can produce in the usual five summer months' operation (April to August) 30,000 to 35,000 tons of dried turf briquets. Improvement has been chiefly directed toward reducing the cost by dispensing more and more with hand labor, both in the winning of the turf and in the after process of drying and storing it until used.

As regards the methods adopted for burning the fuel after is has been dried as described above, a series of belt-conveyors carry the peat briquets to the storage bunkers, and then, after screening and weighing, to the feed hoppers attached to each boiler. The grates are inclined at an angle of 36 deg. to the horizontal, and are divided into two portions, each of 43 sq.ft. superficial area. The halves are fed alternately with briquets by raising a lever that actuates a hinged door on the fire side of the feed hopper.

Since the calorific value of the air-dried peat fuel is low, the draft requires careful regulation in order to avoid great excess of air and a low evaporative efficiency in the boilers.

A steam-raising test made soon after the Wiesmoor plant was started gave an evaporation of 3.01 lb. of water per pound of dried peat, and a boiler efficiency of 73.5 per cent. The mean calorific value of this peat was 4.824 B.t.u., or just about one-third that of good coal. Working out the cost of the fuel from these figures, taking the price of the turf briquets at $1.25 per ton, and the fuel consumption at 11.35 lb. of peat per kilowatt-hour, we find that the fuel required will cost between 0.29c. and 0.34c. This compares quite favorably with the cost of coal in the best managed large modern power stations.

Russia.—Before the war Russia was second only to Germany in the number and capacity of its installations for producing peat fuel. According to Haanel, the number of separate plants in 1910 was 1300, and the

output of machine peat amounted to over 5½ million tons annually. Many private plants existed in connection with cotton mills and other manufactures, some of which were producing nearly a quarter of a million tons of peat fuel yearly.

The method used in these Russian machine-peat plants was similar to that described above—that is, the peat was cut and pulped by a combined type of machine; it was then formed into blocks by hand labor and was finally dried by exposure to the sun and wind in the open air.

Canada. — The Canadian Government in 1909-10 erected a small experimental plant for producing machine-dug peat at Alfred, Ontario, in order to encourage the development of the peat resources of the Dominion upon sound lines. This plant was similar in design and principle to those already described as being in opera-

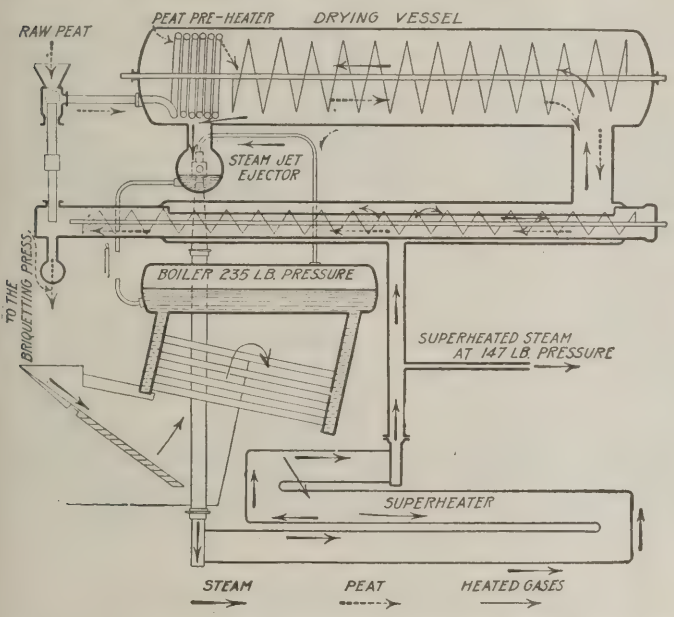

FIG. 6. DIAGRAM OF GERMAN DRYING INSTALLATION

tion in Germany and Russia, the only improvement being that a system of cables was employed to transport the pulped peat to the drying-grounds. The peat produced at this plant in the 1911 drying season had a moisture content of 16 to 20 per cent. and was employed for a series of steam-raising tests in two different types of boiler—a Babcock & Wilcox marine type of water-tube boiler and an internally-fired boiler of the locomotive type. Bulletin 17 of the Canadian Department of Mines contains a full record of these tests, while the table presented below gives a summary of the figures obtained in the six main tests:

	Water-Tube Boiler			Fire-Tube Boiler		
Test number	1	2	3	4	5	6
Net calorific value of the fuel as fired—B.t.u. per lb.	7490	7490	6990	7130	6970	7110
Peat fired per hour, lb.	476	586	569	160	214	341
Peat fired per sq.ft. of grate surface, per hour, lb.	20.5	15.5	15.0	17.7	23.8	37.9
Equivalent evaporation per hour, from and at 212 deg. F., lb.	1950	2322	2250	621	802	1054
Equivalent evaporation per hour, per sq.ft. of heating surface, lb.	2.88	3.43	3.32	2.89	3.73	4.9
Lb. of dry flue gas per lb. of peat	12.4	9.8	11.1	9.8	9.1	6.5
Temp. of flue gas leaving boiler, deg. F.	720	760	715	690	690	750
Equivalent evaporation from and at 212 deg. F. per lb. of peat as fired, lb.	4.10	3.96	3.95	3.89	3.74	3.09
Thermal efficiency of boiler furnace and grate, based on the net calorific value of fuel, per cent	53.1	51.3	54.8	52.9	52.1	42.2

These efficiencies are low when compared with those said to have been obtained at the Wiesmoor power station, but it must be remembered that peat contains a high percentage of hydrogen, and that when heated two-thirds of the combustible matter it contains is liberated in the form of hydrocarbon gases. A large combustion chamber is therefore required with secondary air admission in order to obtain good results with peat fuel. This does not appear to have been arranged for in the Canadian tests.

(To be continued)

Coal Output of United Kingdom in 1918

The output of coal from mines in the United Kingdom during the 52 weeks ended Jan. 4, 1919, is estimated to have amounted to 226,699,000 long tons, being 21,361,000 tons, or 8.6 per cent. less than in the previous year. The tonnage raised in each of the principal districts was:

District	Output, 52 Weeks Ended Jan. 5, 1918 Tons	Jan. 4, 1919 Tons	Decrease in 1918 Tons
England and Wales:			
Northumberland	10,190,000	9,843,000	347,000
Durham	31,070,000	28,397,000	2,673,000
Yorkshire	40,770,000	35,378,000	5,392,000
Lancashire, Cheshire and North Wales	24,980,000	22,518,000	2,462,000
Derby, Nottingham, and Leicester	33,220,000	29,915,000	3,305,000
Stafford, Salop, Worcester, and Warwick	19,770,000	17,624,000	2,146,000
South Wales and Monmouth	48,340,000	46,529,000	1,811,000
Rest of England	5,440,000	4,791,000	649,000
Scotland:			
The Lothians	4,900,000	4,541,000	359,000
Fife and Kinross	6,360,000	6,362,000	*a* 2,000
Rest of Scotland	22,930,000	20,713,000	2,217,000
Ireland	90,000	88,000	2,000
Total, United Kingdom	248,060,000	226,699,000	21,361,000

a Increase.

The year's production by four-week periods, contrasted with the output during the corresponding weeks of 1917, was:

Four Weeks Ended	1917 Tons	1918 Tons	Decrease in 1918 Tons
Feb. 2, 1918	20,430,000	18,830,000	1,600,000
Mar. 2	19,880,000	19,140,000	740,000
Mar. 30	19,840,000	18,760,000	1,080,000
Apr. 27	18,660,000	17,700,000	960,000
May 25	20,090,000	16,860,000	3,230,000
June 22	18,730,000	17,790,000	940,000
July 20	18,990,000	15,780,000	3,210,000
Aug. 17	17,770,000	16,040,000	1,730,000
Sept. 14	19,500,000	17,770,000	1,730,000
Oct. 12	19,160,000	17,890,000	1,270,000
Nov. 9	18,960,000	17,750,000	1,210,000
Dec. 7	19,360,000	16,740,000	2,620,000
Jan. 4, 1919	16,690,000	15,649,000	1,041,000
Total	248,060,000	226,699,000	21,361,000

Comparison between the figures for the months March to June are affected by the dates at which the Easter and Whitsuntide holidays fell in the two years. During the period ending July 20, 1918, the output was heavily affected by sickness among the workpeople.

The approximate number of persons on colliery books at all collieries, excluding those engaged in getting ironstone, fire-clay, ganister, etc., has been estimated to be as follows, taking four weekly intervals.

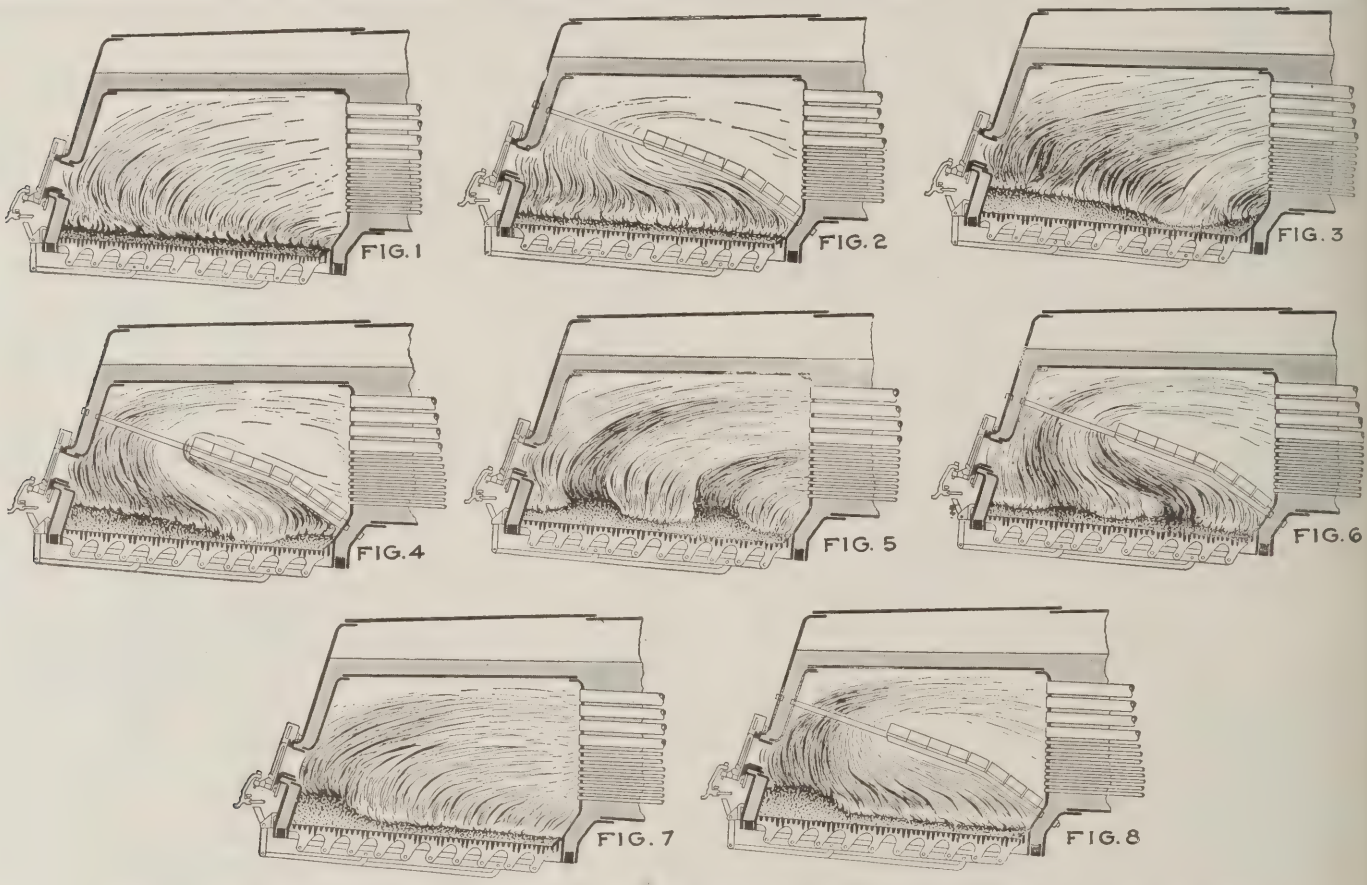
Feb. 2, 1918	985,000	Aug. 17	926,000
Mar. 2	983,000	Sept. 14	927,000
Mar. 30	980,000	Oct. 12	941,000
Apr. 27	957,000	Nov. 9	950,000
May 25	935,000	Dec. 7	959,000
June 22	926,000	Jan. 4, 1919	984,000
July 20	921,000		

The average yearly output of coal per person employed in the coal mines in the United Kingdom was 236 tons in 1918, contrasted with 252 tons in 1914. The average wages cost per ton of coal raised for the 6 months to June 30, 1918, was $2.96, against an average of $1.52 for the complete year 1914. As from June 30, 1918, an additional war wage of $0.30 per day to all persons of sixteen years and over and $0.18 per day to those under sixteen years of age was granted.

Firebox Conditions and Heat Distribution

THE United States Railroad Administration is sending out two sheets showing the conditions both good and bad that may exist in a locomotive firebox, and the distribution and utilization of heat in a locomotive. All data and illustrations are taken from the University of Illinois Experiment Station Circular No. 8, entitled "The Economical Use of Coal in Railway Locomotives." Although the data presented concern especially steam locomotives, it is equally applicable to steam plants in general, particularly those employing internally fired boilers. It is therefore here reproduced in its entirety.

The condition represented in Fig. 1 shows the admission of enough and not too much air. With the grates and draft apparatus in proper condition, a level and uniform firebed permits air to enter without undue obstruction over the entire grate surface and at the same time prevents cold air from entering through holes or thin spots.



With a light, level and bright fire most of the air supply enters the firebox through a uniform firebed. The firebed being uniform, without holes, clinkers or banks, the air enters in many small streams equally distributed over the entire grate surface. Every part of the fuel bed and of the gases just above the fuel bed has its share of the uniformly distributed and finely divided air streams which are entering through the gates.

High and uniform firebox temperatures result from a proper air supply and a good mixture, and most of the coal and gases burn before they can escape from the firebox. High firebox temperatures insure the burning of combustible gases which with lower firebox temperatures escape without giving up their heat.

When holes occur in the firebed the result is too much air in parts of the combustion chamber and not enough air in others. Holes permit too much air to enter the firebox for the amount of coal which is being burned where the holes exist. The air coming through the hole is in a comparatively solid stream, and where this air comes through there is little fuel to burn. At points where there is fuel on the grate not enough air is coming through, and the opportunity for good mixing is lost. The large volume of cold air coming through the hole cools that part of the firebox, and combustion in other parts of the firebox is retarded.

The condition represented in Figs. 1 to 8 shows the results of both not enough air and of too much air. Banks may restrict the air supply to such an extent that there is not enough air to insure combustion. Even though large quantities of air may enter through the thinner parts of the fire or through the firedoor, the combustible gases arising from the banks may not receive a sufficient supply of air before they escape from the firebox. The firebox may be receiving too much air and still not burn the coal because of the poor mixing.

Above the thinner parts of the fire there may be more air than is needed to burn the fuel with which it comes in contact. This surplus air does not assist in the combustion process, but reduces the firebox temperature and carries off heat through the stack.

FIGS. 1 TO 8. ILLUSTRATING THE GOOD AND BAD CONDITIONS THAT MAY EXIST IN THE FIREBOX OF A LOCOMOTIVE

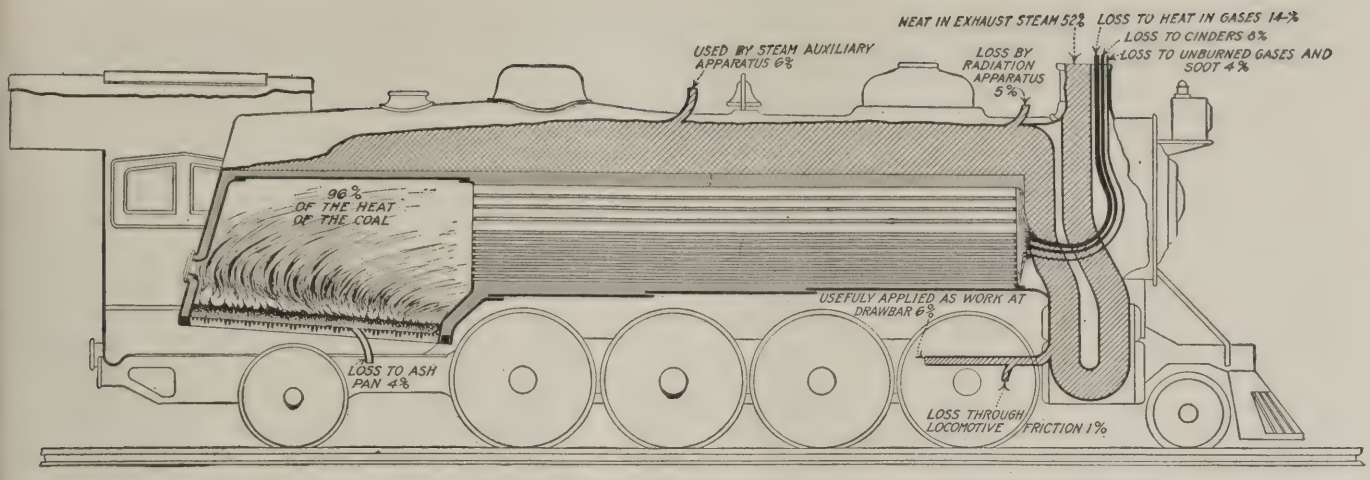


FIG. 9. UTILIZATION OF THE HEAT GENERATED IN THE LOCOMOTIVE FIREBOX

Where the coal and gases are heaviest the incoming air supply is least, and neither the incoming air nor the gases arising from the fuel are sufficiently divided into numerous and well distributed small streams to permit easy and rapid mixing. Gases arising from the fuel bed reach the flues in a very short time and mixing must be rapid.

The banks of green coal and the smoky gas arising from them tend to cool the firebox as a whole. Some parts of the fire burn much more brightly than others and the temperature throughout the firebox is not uniform. Smoke and unburned gases result from this condition.

Combustion in the firebox liberates heat from the coal. Combustion is not complete, and all the heat of the coal is not liberated. Cinders and combustible gases escape unburned from the firebox and pass out through the stack.

Much Heat Escapes with Stack Gases

Some of the heat liberated from the coal is carried out of the stack by the stack gases. Air and coal at a temperature of, say, 70 deg. F., go into the firebox; the gases which they form come out of the stack at 500 or 600 deg. F. For each ton of coal which goes into the firebox about 12 tons of air also go in and about 13 tons of gases pass out of the stack. It takes some of the heat of the ton of coal to heat these 13 tons of gases from 70 to 600 degrees.

The heat liberated in the firebox, except that which is used to heat the stack gases, passes through the firebox sheets, the boiler tubes and the superheater units to the water and steam. Some heat is lost by radiation. This comes from all parts of the locomotive which are warmer than the surrounding air. The most of the heat lost by radiation comes out of the steam.

The heat in the steam is used for auxiliary purposes, is lost as leaks or goes to the cylinders to do work. Some coal is lost to the ash pan and ash pit.

Of the heat going to the cylinders a large portion passes out the stack in the exhaust steam. This exhaust steam produces the draft necessary to force into the firebox and through the firebox, boiler and front end the 12 tons of air and the 13 tons of gases which are moved for each ton of coal fired. That portion of the heat converted into work in the cylinders moves the locomotive and its train. A portion moves the locomotive and its parts, and the remainder becomes work usefully applied in hauling tonnage.

New Byproduct Plant Erected at English Coke Works

A new battery of 35 simplex regenerative ovens has recently been erected at the Lambton Coke Works at Fence Houses in Durham, England. These regenerative ovens were decided upon to avoid the erection of another boiler plant, and many considerations entered into the arangement of the byproduct plant. There was an indirect recovery plant of 35 ovens, including a rotary scrubber, and room for only two 100,000-ft.-per-hour exhausters in the exhaust house. It was therefore undesirable to have two separate streams of gas, as there could not be a spare exhauster for each battery.

It was finally decided to have one stream of gas on the pressure side, the suctions from the two batteries uniting at the exhauster and being regulated by valves. The gas then went through a Pelouse tar extractor to the saturator and, after cooling, to the benzol scrubber, which consisted of the old rotary scrubber rebrushed, plus the former tower benzol scrubbers.

The oven walls in this plant are parallel, which is for obvious reasons a great advantage. It has been said that there were some expanding or salt-containing coals for which parallel walls were unsuitable, but this has yet to be proved. Tapered ovens are a relic of the days when, owing to uneven heating, ovens could not be pushed. Some brilliant genius then thought that by giving a 2-in. taper in 400 in. he would accomplish some highly beneficial results.

Coal Output in Taiwan in 1918

According to investigations made by the productive industries bureau of the Government General of Taiwan, the output of coal for 1918 in Taiwan will be about 700,000 tons, although it was at first estimated that there would be an output of about 1,300,000 tons because of increase in the area of coal mines. The demand for Taiwan coal is increasing in South China with Hongkong as a center. The export of coal to South China since January amounted to 247,676 tons valued at 2,424,150 yen ($1,207,000), the export during November being 22,059 tons. Judging from this, the export of coal for the whole year of 1918 will amount to about 260,000 tons, being 30,000 to 40,000 tons less than originally estimated owing to the scarcity of tonnage.—*Commerce Reports.*

How to Compass Industrial Co-operation*

By Charles P. Steinmetz†
Schenectady, N. Y.

SYNOPSIS—*The author advocates large changes in our industrial management, which he hopes will put our industries eventually in the hand of the workers; but he would do this without haste, confiscation, revolution, or ill will. This proposal is to give labor dividends based on the wages paid and on the amount of excess profits above a certain percentage, the gross returns to labor being made equal to the excess profits allotted to capital.*

THERE are two old sayings: "In unity is strength," and "a house divided against itself shall not stand." If these statements are true in anything, they are true in Mother Industry; and they are particularly true today where modern civilization in the world's war has practically become bankrupt, and when we now, as receivers, have to reorganize the world again.

Our industrial life must be coöperative if it would be successful and efficient. If industry is to take care of the world's work in such an effectual manner as to redeem our civilization from the direful effects of the last few years, it must have coöperation. But can that coöperation be obtained?

The radical labor agitator or socialist tells us there can be no peace between capital and labor. He contends that they are inherently antagonistic and must fight to a finish, because the interests of one are against the interests of the other. Yet in industrial depression the employer as well as the employed suffers. So the old-time corporation president preaches to us that the interests of capital and labor are identical; that if the individual interests are trusted to his keeping they will be taken care of.

At the same time every child sees and knows that a dollar more paid out in wages means a dollar less of profit, and that the interests of capital and labor are different—entirely opposite in some respects. We cannot get any further in solving the problem if we take an extreme view one way or the other. The interests of capital and labor are not identical, but are the same in some respects and opposite in others.

In general, in any industry, those interests which have to do with those outside the industry—with customers, etc.—are usually identical, whereas within the industry the interests of employer and employee are often opposite to each other. Thus there are relations in which the interests of capital and labor are identical and some in which they are not identical, but this is not strange. There are many other relations in our modern civilization where there are both identical interests and unidentical interests. Take buyer and seller, manufacturer and customer, landowner and renter. Their interests are, in certain ways, opposed and still we do not have warfare. Because there are some features where their interests are opposite is not reason enough to make them fight each other.

In all these relations which closely duplicate those existing between employer and employee, the conflicting conditions are not settled by warfare. On the contrary there are often—I might almost say very often—friendly relations between the manufacturer and customer. Unfortunately the historic relation between capital and labor is far different. It has been full of conflict.

Why it is necessary that employer and employees—capital and labor—cannot agree and coöperate in a similar manner? The reason is historical. In the days of small manufacture the employer and employee bore an equal standing as regards industrial power. The organization of employers, as represented by the formation of industrial corporations, meant an increased power on the side of the employer and a disadvantage to the employed. As a result, labor organizations were formed; but conditions had already become hostile.

How to bring the coöperation about, how to return to such conditions as should have remained operative, is the main problem, for it is essential that we bring about coöperation within our industry if we wish to meet the demands of the new world.

Present Differences of Long Standing

It has taken two generations of development to create the present unfortunate situation where differences are settled by fighting, and the situation is so strained that we cannot expect to secure this coöperation by merely wishing or talking about it. It is a long, slow, difficult work which will have many setbacks, and we have to remain at that work and fight zealously for it.

Adjustment must come first from the employers, but not for any moral reason. The present situation is not the fault of labor more than capital. It is merely an historical development of a situation beyond the control of man. The employer must have a broader view than his employees. We must not forget that there are still many imperfections in our civilization. Most serious is it that a large majority of men cannot enjoy such a complete education as would fit them to make the most of themselves, and heads of industry as a rule have the benefit of the broader education and must take the broader view of things. We cannot expect the same broad view of one who left school at fourteen years of age as of a man who has enjoyed a more extensive education.

That the initiative must come from capital is clearly realized. But we must remember coöperation does not mean merely spending a few dollars here and there. The work of social reconstruction is probably the most important which faces us today in the industrial field, and men must devote their time and attention to it; and those attempting to solve the problems involved must give the same high-grade service to that work as is given by those in charge of other administration. We cannot expect to see any positive results until we are really willing to approach it more seriously than in the past, giving it our time and interest, and expending in its solution the ingenuities of the same quality of men and the expenditures of a like amount of money as are de-

*Abstract of address entitled "Industrial Coöperation," delivered before the Editorial Conference of the New York Business Publishers Association.

†Consulting engineer and one of the foremost electrical experts of the present day.

voted to the accomplishment of other industrial objectives.

Coöperation implies two parties working together, not one settling the matter and telling the other, "You must do that and that and then we will coöperate." Unfortunately most of the serious efforts made in this direction have been of that character. The employer has worked out plans and then asked the employees to coöperate along those lines. Very often the plans have been good, and the whole scheme would have been satisfactory if it could have been worked out jointly; but it came as paternalism and was therefore tainted from the beginning. That is not coöperation. It is easy to say we must have coöperation; also easy to find fault. But it is not easy to make suggestions as to how it should be done and how the present strained relations between capital and labor should be overcome. Probably there is no single way to bring about true coöperation. Success in it and the methods to be followed depend largely on local conditions and existent social relations. There is no broad and single way. The old-time industrial relation made an industry the private property of the owner and recognized only capital and not labor. This relation was destroyed forever at the moment when President Roosevelt interfered in the anthracite wage dispute and thus brought both sides to terms.

THOSE WHO HAVE TRIED IT SAY IT WORKS WONDERS
(Copyright 1919, New York Tribune Inc. Reproduced by Permission.)

The other extreme is the socialistic conception that all wealth is created by labor, to whom all wealth, therefore, belongs, and that capital is a parasite on industry and receives its ability to levy a tribute on the workingman by reason of having acquired a monopoly in the means of production. But that point of view is unjustifiable. Industrial production now requires both capital and labor.

The present labor unrest arises logically from a demand for a share in the profits and management of industry. Since both labor and capital are necessary, it is right that they both have a share in the profits and a hand in the management of the industry. There are several ways of attempting to provide for this, but most of them have been unsuccessful. One way is by welfare work. This is important and useful but offensive and insulting when forced on labor in a paternalistic manner.

It is appreciated where it is done, not as welfare work, but merely as a matter of corporate self-interest. We must realize that the quality of a man's work depends on the conditions under which it is done, for on those conditions depend the self-respect and quality of the man. But welfare work will never, especially if we use that name for that class of activity, bring about coöperation. We should rather term it an Industrial Relation Department or Committee, instead of a Welfare Department. The most difficult thing in coöperation is to put yourself in another man's place and see things as he sees them.

Another method attempted for the purpose of creating a unity of purpose between capital and labor is the system of giving bonuses during times of industrial prosperity, and thus interesting the employee in the industry. To some extent this scheme is all right though it smacks somewhat of paternalism. It might work well in Germany, where people have been trained to look up to their masters as superiors, but it leaves a bad taste in the mouths of Americans. They are prone to ask, "Why not give us an increase of wages instead of a bonus?" The bonus system has also the disadvantage that the workman shares only in profit and not in management. Another attempt in the same direction is the committee system, which is claimed to have been put in successful operation in England. There are several forms of this scheme. There are the committees elected by employees which take up with employers all relations of importance both to the company and the men, and arbitrate the wages, hours, etc. Another form is the joint committee system in which half the members are elected by employees and half are appointed by the corporation. This appears to have much in its favor, but here also there are some difficulties. Labor has its own organization, and action of this kind is apt to be taken by labor unions as an attempt to supplant them and deny them recognition. Labor unions claim that they represent the employees. Facts show that in many cases they are right, because while union men may often have a minority among employees, when serious questions arise experience shows, not infrequently, that the majority of nonunion workers follow the lead of the unions rather than of the nonunion committees.

Shop committees are liable to be considered as eliminating the labor unions by establishing a rival union.

While the leaders of industry recognize the necessity for coöperation, the labor organizations thus far do not. But there is another side. Do we want the committee system? Let us assume it is successful. A board of directors acts for the one side and a labor committee or committees for the other. Is this not another alignment for warfare? Have we not in effect organized two different parties to battle with each other?

The last proposition is the wage dividend. Mother Industry requires capital and labor. Therefore both are entitled to a fair rate of wages for the work done. All

profits beyond that belong to capital and labor. These should be divided as dividends, one part being dividends on capital stock, the other being divided on labor stock as determined by the yearly wages received. This system is in operation in a number of companies, including certain electric-utilities corporations among others. It lacks, however, provision for a share in the management.

But we could carry it farther and recognize labor as equivalent to capital and give the labor stockholder the same directing power in the management as the capital stockholder. This would be revolutionary, but both would share in the profits, getting dividends, one on capital stock and the other on what may be called "labor stock."

Both could share in the management and, if the "labor shareholders" so preferred, labor-union officials could hold the proxies and thus watch over the interests of the employees. This does not set up a rival administration but brings about joint control by evolution and not by revolution. The question is, What employees should be recognized as stockholders? Should everyone, even if he joined in the company's operations only yesterday, vote today with those of longer affiliation?

There are many things that show that only those who have been with the organization for a number of years should be recognized as wage stockholders receiving dividends and taking part in the management. We could set the limit at ten years. There would not then be many such voters, and their enfranchisement would not make any radical change in industry. Every year or so the minimum could be reduced till it fell to six or even five years. This would eliminate any opposition except from the extreme socialists who refuse in any way to recognize capital. The workers might be encouraged to buy stock with their labor dividends and so eventually, receiving both capital and labor return, they would finally become predominant in the industry by a natural and desirable evolution. In fact, in the final wind-up, the only stockholders left would be the workingmen.

Thus what we look upon as revolution would be brought about by the peaceful and unopposed forces of evolution. Our society would be socialized with the good will of everybody.

Coal Operations in Newfoundland

A coal company consisting of more than 200 shars holders was organized in the early fall of 1918 to operate and develop the bituminous coal area in the district of St. George's, on the western shore of Newfoundland. By November, 1918, sufficient capital had been subscribed to commence operations, which have been continued to date. An entry has been driven in one seam a distance of 150 ft.; the level of this entry is about 135 ft. below the point where the seam outcrops. Over 250 tons of coal have been mined, and samples used in St. John's are said to have better burning qualities than any now imported. At the beginning of operations the coal seam was 4 ft. 9 in. thick and continued increasing in thickness up to 5 ft. 4 in. at the face of the entry, with every indication of further improvement as operations advance. The entry has opened up about 5000 tons of coal. By the last of May it is hoped the entry will have been advanced an additional 100 feet.

Illinois Mining Institute Meeting

The annual meeting of the Illinois Mining Institute will be held May 22, 23 and 24, on board the "Golden Eagle," which will leave St. Louis at 10:00 a.m. on Thursday, May 22, for Quincy and Keokuk. At 11 o'clock S. T. Jenkins will deliver the address of welcome, to which William Hall will respond. After lunch the afternoon session will start at 1:45 with a paper entitled "Power Transmission Methods in and Around Coal Mines," by W. S. Farnham, mining engineer of the Goodman Manufacturing Co., followed by one by Steve Gosnell on "What Constitutes a Proper and Lawful Examination of a Mine by a Mine Examiner."

At 9:30, Friday morning, J. C. Thompson, director of the Department of Mines and Minerals, will read a paper on "Should the Abandoned Workings of a Gassy Mine Be Sealed or Ventilated," followed by discussion. At 1:30 p.m. J. H. Tracey, electrical engineer of the Electric Storage Battery Co., will read a paper on "Care and Attention That Should Be Given Storage Batteries," and after discussion of this subject Martin Bolt, assistant director of the Department of Mines and Minerals, will read a paper on "What Has Been the Result of the Consolidation of All Mining Agencies in the Department of Mines and Minerals."

On Saturday, at 9:30, a business session will be held, the meeting adjourning at 11:30 on the arrival of the boat at St. Louis. Those desiring to attend the meeting should advise S. T. Jenkins, Boatmen's Bank Building, St. Louis, Mo., not later than May 20.

Convention of National Coal Association

The National Coal Association will hold its annual convention May 21, 22 and 23 at the Congress Hotel, Chicago, Ill. The opening session on Wednesday begins at 10:00 a.m., with a roll call of the association and individual members, followed by appointment of committees; address by H. H. Merrick, president of the Chicago Association of Commerce; business meeting; consideration of proposed amendments to the charter; reports of the president and general secretary. In the afternoon, at 2:30, the reports of the treasurer, finance committee, railroad relations committee, cost accounting committee, foreign trade committee, credentials committee will be read; also report of election of directors by districts and at large.

On Thursday, at 10:00 a.m., the board of directors will meet, after which the meeting will be addressed by Dr. H. A. Garfield, United States Fuel Administrator. At 2:30 p.m. the president of the association will address the convention, followed by A. F. Sheldon, president of the Sheldon School and founder of the Business Science Society, whose address will be on selling coal for a profit. The session will end with questions and discussion.

The morning session on Friday starts at 10:00, with demonstration of an open-price bureau in operation, followed by an address by H. A. Wheeler, president of the Chamber of Commerce of the United States, on "The Sherman Law." At 2:30 in the afternoon Mr. Sheldon will address the meeting on "Bolshevism and What American Business Men Should Do to Meet It," after which a little time will be given to questions and discussions, followed by report of the resolutions committee.

PANORAMIC VIEW OF EXPERIMENTAL MINE AND EXPLOSIVES STATION NEAR BRUCETON, PENNSYLVANIA

The New Pittsburgh Station of the Bureau of Mines—IV

By George W. Harris
Editorial Staff, *Coal Age*

THE Bureau of Mines each year finds an ever-increasing number of problems that require solution. For example, there is the work of the fuel section at the Pittsburgh station, which is under the charge of H. Kreisinger, fuel engineer. The situation regarding the supply and use of fuel throughout the country was most acute during the war period. There were many requests from the public for advice and for special direction in fuel problems, all of which tended to divert the energies of the fuel section from its normal activities; and in the midst of all this, the laboratories of this section were moved from the old arsenal in Pittsburgh to the new building on Forbes Street.

During most of the time this country was in the war the bureau collaborated with various Government organizations, such as the Fuel Administration among others, which required technical information about coal, mining, and allied subjects and industries. The assistance afforded by the chemical and mining sections in these matters has been referred to in previous articles. The station's fuel section took an active part in tests on fuel, boilers and so on, and work of this nature is still being carried on for the United States Shipping Board at Erie, Penn., where marine boilers are being investigated. This research includes the combustion of coal in the furnace and the absorption of heat by the boiler itself—in other words, the combustion and heat transmission processes are followed from the grate through the furnace and the boiler passes up to the stack.

This work applies to all boilers and is of special interest to those operating boiler plants in any industry. Hand-fired furnaces have been worked on up to the present time, but all types of stokers will be taken up by the bureau either in the field or in the laboratory. In this boiler work the temperature at the different passes is measured and the absorption of heat is studied at various points. In connection with this whole matter Mr. Kreisinger emphasizes the following fundamental idea: Coal in a hand-fired furnace is gasified in the fuel bed on the grate, and the vital problem is how to properly mix the combustible gases with air in order to burn them as they rise from the fuel bed. Sufficient air cannot penetrate the fuel bed to accomplish complete combustion; also, it is a misconception to think that the speed of combustion in furnaces depends on temperature. The most important fact is that the rate of combustion depends on the speed with which suffi-

FIG. 1. GROUP OF PITTSBURGH STATION SECTION CHIEFS

Left to right—R. H. Kudlich, mechanical engineer; S. P. Howell, explosives engineer; H. Kreisinger, fuel engineer; L. C. Ilsley, electrical engineer; S. B. Foley, metallurgical engineer.

cient air is mixed with the gases to burn them. The temperature in a furnace is always high enough to actually burn the gases, but the point is that there is not enough air intimately mixed with them to support complete combustion. Steam-raisers should be especially interested in the fuel section's work on marine boilers, and it is this type of boiler which is shown in Fig. 2. Referring to this illustration, an attempt is being made by the fuel engineers to introduce more air into the furnace and to mix it thoroughly with the combustible gases, first drilling holes in the furnace door; second, through holes in a bridge wall erected at the rear of the grate; and thirdly, by means of a transverse air pipe at the first baffle plate. The air pipe has nozzles along its length through which air is directed into the burning gases as indicated. This air should actually penetrate at least to the center of the gases over the fuel bed and a complete mixture be effected.

If combustion takes place in the middle of the nest of boiler tubes, the heat is mainly used to advantage only in the remaining half of the boiler. A consider-

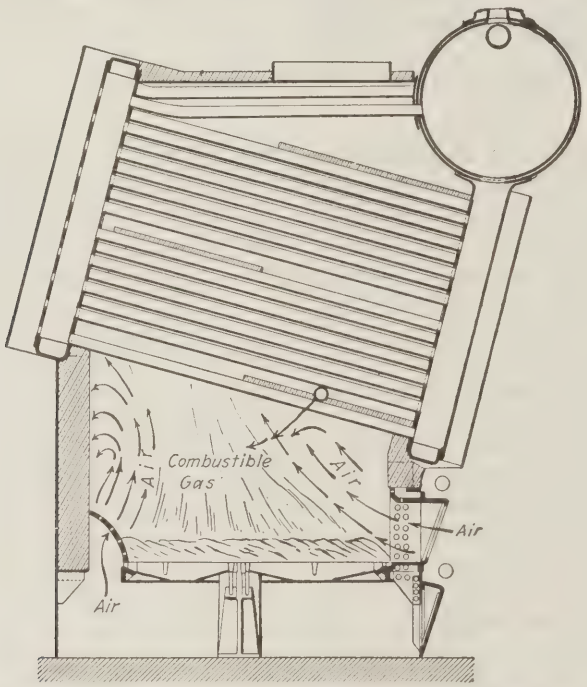

FIG. 2. SECTION OF MARINE BOILER SHOWING INTRODUCTION OF AIR

able percentage of the heat may be lost in that way. Often the flames continue through the boiler tubes into the stack, and this delayed combustion among the boiler tubes becomes quite a factor when the boiler is being driven hard. Proper admission and good mixing of air with the burning gases is a serious problem, and a great deal of information has been obtained in this connection. When the account of these investigations is published it should make most interesting reading. This work on marine boilers has been carried on in coöperation with F. W. Dean, of the Shipping Board, and the general trend has been in the direction of research of somewhat an advisory nature.

The fuel section at Pittsburgh has a large field to cover. Among various fuel activities striking progress has been made in the byproduct coking industry in the United States during the last few years, but the bureau has not been able to keep pace with advance in this field for lack of funds. Furthermore, the byproduct companies that control patents on ovens and processes in this country do not seem inclined to coöperate with the bureau, preferring rather to do their research work privately.

Mr. Kreisinger considers the saving of byproducts extremely important and believes that the byproduct coke oven has the biggest future of any of the methods of using coal. A large part of the bituminous coal should go to the byproduct plant, where the coal will be used to the greatest advantage. Here the byproducts will be saved and the coke can be burned under boilers. Black smoke coming from the coal-burning furnaces is an indication showing that we are using coal in the wrong way. That part of coal which causes the smoke escaping from the boiler stack could be much better turned into gas and liquid fuel. The heat units in gas are worth, for household purposes, eight to sixteen times as much as the same B.t.u. in coal under steam boilers. This attitude taken in regard to the proper method of using coal is from the standpoint of the fuel engineer. The chemist handles another phase of the problem, that connected with the drugs, dyes and other byproducts derived from the coal tars.

Powdered fuel offers another field for research work which the bureau will enter into energetically in the near future. Considerable progress has been made in the utilization of coal in this form commercially, and the fuel section plans to investigate processes already in use rather than to originate new methods. Those who have experienced difficulties when using powdered fuel will be assisted if they will coöperate to the extent of contributing the carfare and expenses of those sent to investigate such matters at their plants. First, the bureau will go to the plant where it will aim to locate troubles by trying out the process on a large scale. Then work on special individual problems will be carried on in the Pittsburgh laboratories and an effort will be made to solve them. Work of this kind will be started in the next few months and as much time devoted to it as is given to hand-fired problems.

Among other things, investigations will be made of what actually happens in the combustion space of a powdered-coal-burning furnace. There seem to be two main problems in firing powdered coal under stationary boilers—ash disposal and ability of the furnace to stand the temperature and effect of the slag. The furnace firebrick is affected physically by the slag deposited on it, and its chemical composition is also changed. But these problems are more or less common to steam boilers fired by any method. A study will be made of the composition of the ash and then an attempt will be made to devise a brick to stand up to the work. An endeavor will be made to lower the temperature, say to 2400 deg., and to do this by having the furnace absorb the heat close to the point where it is generated rather than by excess of air. The bureau will also take up the investigation of heating furnaces used by steel and other plants in which powdered coal is burned.

The problems just mentioned are some of those occurring to a practical man at first sight. Other investigations will go on by momentum gained in war work. Some kinds of work may not seem to be so important, but they are valuable research investigations nevertheless—for example, heat transmission in steam boilers among others. Heat-transmission apparatus will be installed in the fuels laboratory to test the efficiency of boilers under different conditions—using tubes of different diameters and lengths, for example; also, the

effect of initial temperatures, the velocity of gases and scale will be matters considered in connection with the efficiency of a boiler. Furthermore, small furnaces will be installed in the laboratory for testing the combustion of anthracite and coke, also carbon in soot. The combustion of coke is especially important to metallurgists. Some coke dissolves or is eroded rapidly in furnaces; other coke may not be quickly enough affected by heat. Tests will be made on coke of various physical make-up. While a considerable part of the fuel section's work is connected with the details of special problems, nevertheless much of its research has to do with the first principles which control the uses of coal.

A big field for research work at present is the utilization of lignite. The Government has recently appropriated $100,000 for investigations in this field, and the bureau is preparing to take the matter up intensively. Lignite in the main is used locally—in agricultural districts and in sections away from manufacturing centers. Speaking generally, 55 to 60 per cent. of the heat value of lignite is realized, whereas 65 to 70 per cent. efficiency is obtained in the case of a good coal. This difference is partly due to the moisture in lignite. A properly designed furnace should improve the efficiency. A promising future opens up for lignite when used in gas producers. Here the moisture in the lignite is not so detrimental. In general, it is necessary to fit this fuel to market conditions and put it to such use for which it possesses natural advantages. The same is as true of lignites in Texas as in the Dakotas, but in the former state the lignite deposits are within 50 miles of the coast, and may be utilized for industrial purposes.

Those investigations relating to the prevention of electrical shocks, electrical fire hazards and the initiation of mine explosions by electric sparks, flashes or electrical phenomena are conducted by the electrical section. This section is under the direction of L. C. Ilsley, electrical engineer.

The Bureau of Mines has developed a system whereby mine apparatus that meets certain requirements for safety is approved as permissible for use in gaseous mines. The electrical section has done considerable work in this connection. A number of motors for use with coal-cutting machines have been approved and several types of electric miner's safety lamps have been developed and are on the permissible list. These approved lamps are being widely used by the miner. They materially increase the safety of mining and also in many instances increase the efficiency of the workman.

This approval system is worthy of a few words in explanation: Several steps enter into or lead up to the establishment of a line of permissible equipment: First, a decided need for such approved apparatus must exist. Being assured of the need, a preliminary investigation is made of such apparatus as is then on the market or contemplated. From information thus gained an official schedule is prepared outlining conditions under which tests will be made, fees to be charged for conducting tests in conformity with the schedule, etc. These schedules are sent out to anyone interested in that particular line of equipment. This gives every manufacturer an equal opportunity, which is entirely optional on his part, of submitting equipment and having it on the Bureau of Mines permissible list.

In the past a number of manufacturers have submitted equipment to be tested under permissible schedules with a resulting improvement in equipment and greater safety to the mining public. The future of this system is assured. The calls for new lines of approved mine equipment are frequent. Such a system bearing so intimately on questions of safety can not but have a bearing on mine compensation insurance. It seems probable that insurance rates will be reduced wherever permissible apparatus is adopted. If such is the case, there will be an added incentive for purchasing approved equipment. No police power is exercised by the Bureau of Mines as to the use of approved equipment in the several states, but many operators insist upon apparatus having the permissible seal of the bureau.

The electrical section is at present occupied with the tests of equipment submitted under the different permissible schedules and in conducting preliminary investigations to obtaining data for the establishment of new schedules, chief of which are for shotfiring batteries and storage-battery locomotives. In addition to the foregoing the section is interested in rules and laws connected with installation, inspection and maintenance of electrical equipment.

In all investigations bearing on the approval of equipment an effort is made to be practical. Laboratory tests

FIG. 3. MOTOR TESTING GALLERY NO. 5

are followed up by field investigations. Also, all approvals are conditioned to satisfactory field performance. Several bulletins and technical papers have been published covering different activities of the section.

Motors for use on various mine equipment are tested in gallery No. 5, shown in Fig. 3. This testing gallery is located just outside the main building adjacent to the south end of the chemical wing, and consists of a steel shell arranged so that air and gas can be mixed in it in any proportion desired. It is surmounted by a small crane by which the lid of the gallery may be removed to allow pieces of machinery to be lowered into it. To prove the suitability of motors for use in atmospheres containing firedamp, the motor to be tested is placed in the gallery, which is then filled with an explosive mixture. It is also made certain that this gas mixture fills the case around the motor itself. The gas inside the motor is now ignited. The protecting case to the motor

is considered satisfactory provided no flames issue from it and provided the gas in the gallery outside the motor is not ignited by the explosion which takes place within the motor. Fifty or more tests are usually made for each motor investigated. In addition to this test, the apparatus is carefully inspected to see that all motor casing joints have proper flanges; also, to see that there are no through bolt holes or other openings which will permit flames to pass to the outside. It is assumed that gas will be fired in the motor case at times, and the explosion must not propagate from the motor to the surrounding atmosphere.

Interesting investigations are being conducted in the mechanical section at the Pittsburgh station by R. H. Kudlich, mechanical engineer, under the direction of the chief mechanical engineer of the bureau, O. P. Hood, with headquarters at Washington, D. C. Mr. Kudlich is investigating mechanical appliances used about mines, with special regard to safety. At present safety catches for mine cages are receiving attention, and this work will lead to the establishment of a schedule for the approval of this type of apparatus similar to the plan followed by the electrical section and to the development of really efficient safety catches. Much other mine equipment will be similarly investigated in the future. Shaft gates, overwind devices, cages and skips, hoisting ropes and other mechanical haulage devices are a few of the many things considered as problems for investigation. These all have to do with the safety of the miner and naturally have first place. But conservation of resources and elimination of waste also constitute an important part of the bureau's work. Under this latter would logically come the economic handling and preparation of coal in the mine and on the surface.

We consider our work always in a course of evolution, says S. P. Howell, explosives engineer, in charge of physical tests of explosives and blasting supplies of the bureau. Additional tests are instituted from time to time if they mean increased safety or efficiency in the use of explosives. Changes in the methods of the explosives section are made after due consideration and study of conditions, or after conferences with the users or manufacturers of explosives. The headquarters of the explosives section is at the Pittsburgh station. Here also the explosives-chemical work is done. But physical tests of commercial explosives are made at the Explosives Experiment Station built adjacent to the Experimental Mine near Bruceton. The men carrying on this work have the proper sociological benefits. An up-to-date wash and changehouse has recently been installed for both the mine and explosives station men. Also a clubhouse has been completed where single men may live and where hot lunch may be served to all employees. It is hoped that in time houses may be built at this field station for employees with families.

FIG. 4. PORTION OF ELECTRICAL LABORATORY SHOWING APPARATUS FOR TESTING EQUIPMENT

With such improvements in view, the bureau expects to acquire more land for the purpose.

The explosives testing station was built for peace purposes, but a great deal of war work was done there for the United States Engineers and the Ordnance Department. These special investigations are about finished now and peace work will start again. At this station tests are made primarily of all explosives and blasting supplies used in mining operations, and a large portion of the time is used in testing explosives to determine their permissibility for use in coal mines. An important special work recently has been the proving of the practicability of T N T for industrial purposes—but not for use in coal mines. A tremendous quantity of this explosive was accumulated in this country for war purposes. The present tendency seems to be to divert this valuable asset essentially to Government departments—that is, to have the Reclamation Service, the Alaskan Commission and other similar projects use all this explosive.

FIG. 5. BOMBPROOF FOR TESTING EXPLOSIVES

The explosives section has been doing some T N T research work, but in a way not to interrupt the regular work of this department. At present requests from manufacturers have been made for tests of about 40 explosives—so there is a quantity of work on hand. The metal-mining men especially want to know what gases are given off by explosives. This is important, for in metal mining much larger amounts of explosives are used than in coal-mining work, and the ventilation is not so good in a metal mine as in coal workings.

A good view of the new Explosives Experiment Station buildings and the plant at the Experimental Mine is given in the headpiece. The former buildings have only recently been constructed. However, the apparatus used at the old arsenal was set up here and in moving such equipment from the old site and establishing it at the new station improvements were effected in installation and operation. The various pieces of equipment are distributed in three buildings which are located about 50 ft. apart. The fourth building is an office.

The old gas and dust gallery moved from the arsenal grounds to its new location here has been described in the Aug. 25, 1917, issue of *Coal Age*, under the title, "Coal Mine Investigations—III." This gallery is a steel tube simulating a mine entry and has an internal diameter of 6 ft. 4 in. and a length of 100 ft. The new features added to it include an extension of 145 ft. consisting of a 20-ft. movable section between the old and the new parts. This gives a gallery 245 ft. long. The 100-ft. portion of this tube will be used for testing the permissibility of explosives. When the movable section is in place it will form a gallery which the Experimental Mine engineers propose to use for testing the explosibility of various coal dusts. The ballistic pendulum, large and small impact machines, pendulum friction device, Bichel gages, calorimeter and flame tests apparatus are used here the same as at the arsenal. All buildings here are constructed of hollow partition tile with stucco outside and concrete foundations and floors.

The bombproof, where the rate of detonation of explosives is determined, is constructed entirely of concrete and the greater part of it is below the surface of the ground on the hillside (see Fig. 5). The top is well reinforced with iron rods; 1-in. armor plates protect the top and sides of the interior against shots. Considerable war work has been done here. It was started in August, 1918, and is still going on.

Shortly the explosives section will carry on similar work to the war research, with permissible explosives. In making these tests the explosives are placed in tubing through which four wires pass transversly. From the bombproof the wires are carried to a Mettegong recorder in an adjacent house, as shown in Fig. 6; it registers the interval of time between the breaking of each of the four wires passing through the explosive in the bombproof. The practical value of this work lies in the fact that explosives with a high rate of detonation have a great shattering effect.

One of the most recent sections to be instituted at the Pittsburgh station was the metallurgical. This section was organized during the war and was run on a coöperative basis with the Ordnance Department. Samples of steel which went into service under the War Department passed through the metallographic laboratory at Pittsburgh. Here steel was examined under the microscope with respect to general conditions as to heat treatment and quality of metal. An intensive study from the viewpoint, both of the laboratory and the plant, was made of certain defects which occasioned the greatest trouble to ordnance manufacturers with the idea of locating their cause and finding means for prevention. Not only was steel examined here, but non-ferrous alloys as well. Out of this war work various problems have come forth in the field of iron and steel and ferrous and non-ferrous alloys to which this section is giving its attention. In this connection an instance can be cited—the investigation of ferromanganese production in the blast furnace, which started during the war, is being carried to a conclusion and will doubtless lead to excellent results.

With the reorganization of the Bureau of Mines personnel after the war, there will be quite an increase in the Pittsburgh station force. At the present time, says Mr. Lyon, there seems to be two branches of research which should be emphasized at this station in addition to the investigations already being carried out there; that is, work on fuels and in the line of ferrous metallurgy. This station being in the world's greatest coal and iron industrial center, it will be possible to make a most intimate study of both problems. All these advantages and the splendid equipment of the new building should attract to the Pittsburgh station other high-class men wishing to undertake research work and make this the greatest technical laboratory of the world.

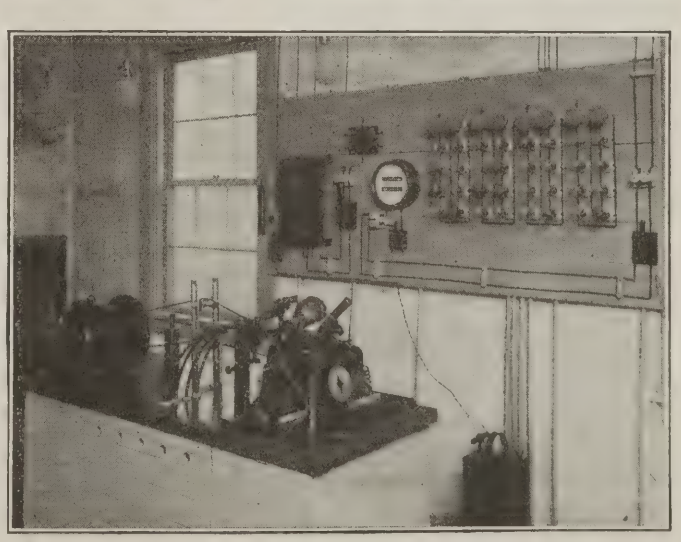

FIG. 6. METTEGONG RECORDER FOR REGISTERING TESTS

Some of the Problems That Beset the Exporting of American Coal

By far the livest matter of coal interest in Washington this week is the export problem. The fact that the plans being worked out by an interdepartmental committee have been kept as secret as possible has caused much additional speculation.

Some features of the plan, which have leaked out, are not meeting with unanimous approval from the coal industry. It is stated that the Government is more interested in supplying coal to meet a temporary demand in certain European countries than it is to pave the way to build up a permanent exporting trade in South America and elsewhere, and is anxious to obtain detailed supervision of this export trade.

Italy is said to be requesting 1,000,000 tons of American coal each month. Switzerland wants 60,000 tons a month. France wants 5,000,000 tons to be delivered at Mediterranean ports during the next twelve months. Northern Africa will require some 2,000,000 tons during the next year. Some of the coal men are inclined to object to having their industry turned into an eleemosynary organization without some compensating advantages. This is especially the case when England is busy making five-year contracts and otherwise doing all it can to reëstablish itself in South America.

Despite the exceptions which are taken to the preliminary plans which are being worked out, there is reason to believe that a program will be arranged which will allow much of the emergency coal to move to Europe and at the same time secure for coal exporters some valuable assistance from the Government in obtaining permanent business.

Some predict that before many years practically all of the coal for Mediterranean ports will be brought through the Dardanelles from the Russian mines. The possibility that some of the coal producing nations of Europe may have foreseen this condition is thought by some to be the reason why they are willing now to allow themselves to be undersold in the Mediterranean by American coal.

A combination under the Webb Act is not looked upon with favor in some quarters. It is felt that the export coal business must be handled by a private corporation. Five factors enter into export coal: Production, selling, financing, transportation and docking. It is feared that the producers of export coal will not be willing to pool their outputs. Central Pennsylvania and West Virginia producers, for instance, might not be willing to pool their outputs. Various districts might be mentioned where such an agreement would be very difficult indeed to obtain. In the same way, there would be too much conflict between the existing selling organizations to allow their activities to be pooled.

The other three factors, however, can be pooled. The railroads will look after the docking in the United States but the business of exporting coal is too young to attract the capital of individual American companies into the uncertain field of dock-building in foreign countries. As a result, other docks must be obtained. In many cases, these are already in the hands of the English.

Shipping is uncertain. Therefore, it has been proposed to leave production unrestrained and selling on the other side unrestrained. At the same time, it is suggested that a few of the large corporations combine to look after financing, ocean transportation and foreign dockage. A powerful corporation of this character could make contracts with those in control of ships, which would provide for the carrying of coal in any quantity to any place. Temporary or permanent docks could be provided as needed and arrangements could be made with bankers, so that coal operators could get their money when their coal was dumped at tidewater. Under this plan, the inspection of the coal would be placed in the hands of the Bureau of Mines, thereby insuring the receipt at foreign destinations of coal conforming to Government specifications.

Uniform Bill of Lading Prescribed by the Interstate Commerce Commission

Proposals looking to a special form for bill of lading for coal shipments were dismissed by the Interstate Commerce Commission on Apr. 30, when in its bill of lading opinion, is said briefly: "We are not convinced, upon consideration of all the facts of record and the arguments made in advocacy of such bills, that they are essential. It is believed that the uniform bills prescribed will be adequate to care for any peculiar requirements of such traffic."

The opinion covering the matter of bills of lading is regarded as one of the most important ever issued by the Commission. It does not deal with the negotiability features of bills, those matters having been definitely taken care of by the so-called Pomerene Act. It discusses the fundamentals and history of the common law of the carrier's liability and its contractual exemptions from and limitations of liability, tracing the development of the law in this country down to the time when Congress, by reason of conditions that had come about and in view of the decisions of the Supreme Court sustaining the validity of contractual limitation in many important cases, found it necessary to enact legislation imposing certain specific duties upon

carriers respecting the issuance of bills of lading and making unlawful some of the exemptions and limitations of liability for which, under the common law, they had theretofore been free to contract with shippers.

The report is accompanied by forms of bills of lading which the Commission finds would be just, reasonable and lawful to be used upon the lines of all carriers subject to the act to regulate commerce.

Program of Convention of American Wholesale Coal Association

The main features of the program of the American Wholesale Coal Association's convention, which is to be held in Chicago June 3 and 4, have been decided upon. J. D. A. Morrow, vice president of the National Coal Association; James F. Callbreath, secretary of the American Mining Congress; John E. Lloyd and W. R. Coyle will discuss different phases of coöperation between different branches of industry. George Otis Smith, the Director of the United States Geological Survey, will deliver an address on "The Best Use of America's Coal." Gibbs L. Baker will speak on "The Wholesaler in Coal and His Taxes."

Government control is to come in for discussion as follows: Do the Wholesalers Want the Government to Help the Coal Trade in Any Way? by C. M. Moderwell. Subdivisions of the question will be discussed as follows: (a) To hold reserved coal land in reserve until needed—E. W. Parker. (b) To modify anti-trust laws with respect to the mining industry—E. W. Sims. (c) To help with the practical movement in conservation—Van H. Manning. (d) Do the wholesalers believe that politicians could be compensated in any way for thus serving the public purpose? That is, in exchange for help given the coal industry, is it necessary to give the politicians any power over coal; or should Government help be demanded as a right inherent in the coal industry?—L. Romanski.

Coal distribution in several of its phases is to be discussed by Gibbs L. Baker, E. M. Platt, J. V. Mayhew and D. C. Shoemaker. Railroad control is to be discussed by George H. Cushing.

A banquet will be held the night of June 3. Noah H. Swayne, F. S. Peabody and G. H. Cushing will be the speakers. The convention also will listen to the regular reports of officers and committees.

Suggests a Coal Policy for Alaska

In a report submitted to the Alaskan Engineering Commission, Andrew Christensen declares that the following must be considered in adopting a coal policy for Alaska:

1. Whether there should be any change made in the coal land leasing law of Oct. 20, 1914.
2. Whether there should be any changes made in the terms of the present lease and the leasing regulations under the law.
3. Whether or not the Government should undertake a thorough prospecting of all the leasing units in the Bering River and Matanuska coal field.
4. Whether the navy should undertake the mining of coal under the million-dollar appropriation.
5. To what extent if any should the Government undertake the mining of coal.
6. Should the Government interpose objections to the construction by private interests of railroads into the Bering River coal field.
7. If so what should be the policy of the Government with reference to furnishing the necessary transportation facilities for the Bering River coal.
8. What steps if any should be taken with reference to furnishing necessary transportation facilities for coal between Alaska and the States.

These questions are all vital to the success of the development of the coal industry in the Territory and should be given immediate and careful attention.

The Alaskan Engineering Commission itself is actively engaged in the mining of coal. Its mining work is in charge of Sumner Smith. The principal work is being conducted at Eska and at Chickaloon.

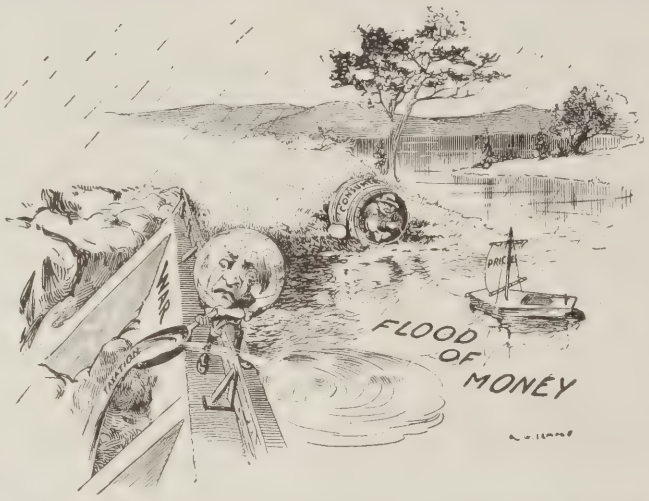
Believes Large Savings Possible in Mining and Marketing of Coal

By stopping the waste in the operation of coal mines, it is possible to cut the cost of production by 40 per cent. of what it was formerly. By avoiding waste in wholesaling, it is possible to cut the wholesaling cost 16⅔ per cent. under what it has been heretofore. The cost of retailing coal can be cut down 33⅓ per cent. These conclusions are those of George H. Cushing, secretary of the Wholesale Coal Association, who has made a careful study of the matter. To illustrate the principal waste in the retailing of coal, Mr. Cushing cites a personal incident:

"I have a friend in the retail business, and I have a house in the suburbs of Chicago. One winter I wanted to buy 20 tons of coal. I gave the order to my friend. His yard was in the south end of Evenston. I lived in the south end of Winnetka, 7½ miles away. The retailer took a $5000 truck and delivered those 20 tons of coal. In doing so, he drove his truck past the yards of 25 retailers and passed 35 public team tracks. On the day he delivered coal to me there was a delivery of coal from Winnetka to Evenston."

Regarding the anthracite situation, Mr. Cushing believes "it is going to stay down until autumn. We are going to have a shortage of anthracite next winter."

New Specification for Army Coal Will Embody Wage Scale Clause



Because the War Department specification for 2,000,000 tons of coal for Army stations for the fiscal year, beginning July 1, contained no clause as to the wage scale of miners, it has been withdrawn. A new specification is being prepared which will include a wage scale clause. It is believed that the matter was an oversight and that the War Department had no idea of not recognizing a labor situation which other Government departments thought it wise to acknowledge. The contracts being made by the Bureau of Mines for fuel for the Government coal yards contain the following clause:

It is agreed that, whenever a change in the mining rate is accomplished or followed by a change in the same direction in the day-wage scale, for every cent of increase or decrease in the mining rate there shall be an increase or decrease of two cents in the price to be paid for the coal furnished under this contract; for every cent variation in the mining rate, not accompanied or followed by a change in the day-wage scale, there shall be a change in the price of the coal equaling the change in the mining rate; and should there be a change in the day-wage scale only, or should the mining rates change in one direction and the day-wage scale change in the other, the price of the coal shall be adjusted accordingly.

EDITORIALS

Still More Media of Credit

THE war added immensely to the currency and to the credit media of the nations. The world will try to ladle out the flood by making taxation large enough to gradually extinguish the debt. How large is that flood and how small is the ladle! Surely the task will be long. Meantime we have floated a further loan and increased still further the media of credit. We are even now incurring more indebtedness by the conduct, at a loss, of our railroad affairs; for that loss will have to be met either by a further loan or from taxation revenues, in which latter case it will prevent or delay the reduction of our debt. The other nations are facing a similar condition. The people are clamoring for social reconstruction on the top of the expenditures for the war. They are like the woman who, when her husband purchased an automobile, seriously crippling his financial standing, wanted to know why he did not also build her a home. The workers are saying, "If you expended so much on the wastes of war, why can you not expend a like amount on the construction work of peace or on the lowering of prices?"

CONSUMER (in the barrel)—It keeps on raining, and the old fellow makes slow progress ladling out the flood with his saucepan. A sure guess is that the good yacht "Prices" will sail even higher before long.

Because of such reasoning the nations are increasing their debts and their instruments of credit. They have programs which will make it hopeless for them to do much more than "break even" year by year. They are to be congratulated if they do not borrow further and heavily.

Thus to the stately wall of obligations erected during the war is added the flash-board built up during this reconstruction period. Will the flood subside? The better guess is that is will rather rise day by day. The small, but much deplored, national debts that preceded the war, were, as we all remember, but little reduced year by year.

For this reason we cannot expect lower prices, but may have to look with dread lest the prices rise higher than will serve merely to stabilize business.

Company propaganda is a little new. Just as the activities of the union in creating divisive sentiment were, when new, regarded as a crime, so the activities of the operator in creating a coöperative sentiment between capital and labor and emphasizing certain economic truths are regarded as offensive and improper. Yet surely the operator is justified in saying something in his own defense.

Our New Period Needs a New Press

PLAYING a popular chord is a favorite sport of newspaper men. They quite generally learn the kind of tune that takes the public ear, and they play it, whether they approve it or not. A sample of such subservience to the public taste is afforded by the following quotation from a leading Philadelphia paper.

"Petitions are being prepared, it is understood, to ask the county commissioners to raise the coal-land assessments in Northumberland County to somewhere near the real value of the properties. It is generally agreed that the present assessment of $17,000,000 on all anthracite owned in Northumberland would be entirely too low as compared with anthracite values which have advanced with leaps and bounds since the war started. If anthracite properties are to be assessed at what they are really believed to be worth, it is said, they would go up into the $10,000,000,000 or more. But this cannot be expected and if the assessment is raised to $50,000,000 it will probably be resisted in the courts.

"T. Ellsworth Davies, Scranton, mining expert, says there are 3,803,710,965 unmined tons of anthracite coal in Northumberland. Figuring this at $4, which is $2 under the lowest market price of $6 a ton, the valuation of the coal properties, it may be seen, would look like $12,000,000,000."

But why figure the value of the coal in the ground at $4 a ton when it is only rarely worth one-eighth of that price. But if it were really worth $4 as suggested, what would the capitalized value be of $15,214,843,860, payable in equal installments for 631 years and 10 months; for the coal, if all obtainable, would take that length of time to extract at the rate of production in the year before the war. Certainly, it would be prodigiously less than $12,000,000,000. All the coal that would be mined 100 years from today would have absolutely no present value, as any actuary would promptly assure us. Another consideration presents itself: The tonnage estimate is a marvelous calculation. If memory serves us, it sets the life of the anthracite region, at least of the Northumberland field, far beyond the bounds of any other estimate.

No attempt is here made to set out the actual status of the Northumberland field. That is best left to the experts who are acquainted most intimately with its conditions. All that has been done has been to indicate broadly how fallacious is the estimate of the

newspaper correspondent. No one can excuse a misrepresentation which overlooks all the many costs and puts the value of the coal under the hill at a figure $2 below the market price.

With three times as much currency as before the world war, it is easy to imagine what will happen as soon as business moves along with assurance and speed. Just now, money is not moving; but as soon as it gets active it is quite unlikely that prices of materials and labor, especially of the depressed nonunion labor, will remain at their present level.

Essentials of Bolshevism

BY REASON of his orderly, logical and careful presentation of his subject, Dr. Steinmetz, in an address delivered before the Editorial Conference, and printed on page 904 of this issue of *Coal Age*, admirably disguised the fact that he was advocating the essentials of bolshevism, which we believe are rightly defined as the advocacy of "the ownership by the worker of the tools of production." He carefully sifted out all the elements of class hatred, for such matters can find in him no answering spirit. They are not of the essentials of bolshevism, but an excrescence which is so common that we have come to regard it as inevitable.

Mr. Steinmetz does not believe in revolution but in evolution. He does not, after the manner of bolshevists, regard the manual worker as having an exclusive right to existence. His doctrine is not unlike that held by many of the largest and best of capitalists, though they might not accompany him on so long an excursion as he has taken. The system he advances might be called "industrial democracy," but it seems to go further and is in many ways safer, for an industry is better protected when the workingmen have a financial interest in its conduct than when they have merely directive powers without any financial risk to run.

The reader will enjoy Mr. Steinmetz's remarks. They sketch amazing possibilities of coöperation. Everyone would like to believe that what he has drawn is a symbol of something which may exist sometime, somewhere in the future.

The capitalist is not by any means adverse to a just and well-ordered existence when all will work together, as do the men on a college athletic team. There is no reason why, if that spirit and quality would enter into every one, any captain of industry should fear at all the advent of the industrial democracy that is being so widely heralded. If it is only like this, he will say, it cannot come too soon.

Some of us who have been on drives for the Red Cross, the War-Work Campaign, Liberty Loan, hospitals, orphanages, churches and what not, and felt with what ardent coöperation everyone—capitalist and workingman—is ready to respond to the demands of his fellow and the community, have on our return been ready to say: "Here is material for any kind of a republic—bolshevist, socialist, anarchist or what not." But, unfortunately, we are hampered all the time by the exceptional men, those who have no social spirit and in whose hearts are found only negative qualities. We could leave our doors wide open at night without fear of 90 per cent. of the passers-by. At least that portion would leave our goods wholly unmolested. What an argument for anarchy! Unfortunately, the other 10 per cent. might rifle the premises from end to end. What an argument for bolts and bars, and laws and capitalism!

Dr. Steinmetz admits that the advances should be made tentatively, and with care. He advises us to try it first on the older hands in the factory, because that is fair and prudent. Alas, the union objects to making fish of one and fowl of another. For a precisely similar reason, the union leaders are opposed to service pensions because they bind certain men to the corporation and make their interests inimical to the other men in the employ of the same corporation. Still, service pensions exist, though it is known that they do create this friction and prevent changes of employment and also cause discrimination between employees. In every scheme some faults may be found, and any scheme succeeds only if all parties approach it in the right spirit. All schemes must fail if their accomplishment is ventured in a spirit of suspicion and anger.

Unfortunately for Dr. Steinmetz's suggestion, those factories and mines that are moving along smoothly do not feel keen for so radical an innovation, even in small doses, while those business institutions that are alive with dissention are poor places in which to try it. In small concerns the difficulties are not trying enough for the owner to act, for there is always a better accord between employer and employed; and in large concerns the risks to be run are considerable, for the brotherhood feeling is hard to develop. Facts like these make experiments in bolshevism less likely than might be wished and somewhat hopeless if tried.

Industrial democracy and its associated schemes like political democracy demand not merely a new system, but a new people—men who understand economics and business, men who are open to improvements and changes, and will adapt themselves to them; an educated, coöperating and idealistic body of men. The qualities can be acquired, let that not be for a moment doubted. Democracy is a breeder of the qualities it needs for its perpetuation. It gives the strength and judgment required for its own consummation. We must move slowly upward toward a new day, whatever that day may be—a day when we shall be free as air and restrained only by our moral consciousness—anarchy—a day when we shall be regulated by the mind of the mass in every action we perform—socialism—a day of the new capitalism when every worker will own the machinery and direct his own employment—bolshevism—a day when we shall help direct our employment but not own the machinery of our trade—industrial democracy.

All the new isms are so strange and uncertain. No wonder some of us cling to capitalism with its dynamic urging toward maximum production and effort, and with its checks on unproductive operation. It is frankly based on what can hardly be called a virtue—self service—but its operation has been modified again and again by considerations of a nobler nature.

Steinmetz makes us think, and think kindly, and thoughts of this kind never are amiss. A kindly thought is in itself a revolution.

Proclaiming loudly the prevalence of graft, dishonesty and self-seeking, the advocates of industrial democracy, bolshevism, socialism and anarchy demand a new order which can only be successful if the crimes enumerated are banished from the human race and a reign of public spirit and self-sacrifice replaces ambition. Eras of trial must pass before we can hope for that consummation.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

While the labor situation seems marked only by trivial and local strikes and strike threats, and appears just now to be developing no new underlying policy, it must not be forgotten that the advocacy of the shorter day and shorter week and nationalization of mines is still proceeding. Because these aspirations do not, at the moment, cause strikes is no reason why they should not be viewed with apprehension and met by argument.

Some mine workers probably will say there should be no argument. They want both shorter time and Government ownership and they will have both or know why. They may be borne with, and with patience. The same position was at one time taken by the reactionary capitalist. "It is my capital," we have all heard him say. "They may take the job or leave it." "It is my labor," the workingman responds. "They may use it as I say or leave it." But no one can afford such an uncompromising stand. We, none of us, have the right to demand compliance to a new regulation without granting the party thus inconvenienced a parley and definite consideration. No one can lay down the law and say, "I have said so and that settles it." Neither labor nor capital must be arrogant, or the world in general which must be served by both will stand by neither, but by its own interests and rights.

ENTER THE CONSUMER, MASTER OF US ALL

If certain laboring men propose to act the drone, or profiteer, or restrict production, or oppose development, the great master, the consumer, will not brook that attitude. Only a consumer who, himself, in his employment, is already demanding equal ease, equal profiteering, equal restriction of product and is similarly opposing development will stand side by side with the laboring men in question.

We must all be citizens of a common country, working for one another, not conspiring against one another by unions and combinations to make each other pay more or receive less, unless, indeed, we happen to be victims of a real injustice, which cannot otherwise be righted.

But there are incidental items of news to record and discuss, and it is well to turn to them, as illustrating the progress of labor adjustment. On May 2, Charles P. Neill handed down a decision under which 200 contract miners of the Lehigh & Wilkes-Barre Coal Co. will receive much back pay for work done since 1917. The men had urged that they should be paid for the removal of rock in the robbing of pillars. Pillar work is, of course, less onerous than advance work. Everyone is looking for pillars to draw, and it is therefore quite the ordinary practice to let out such work without any of the compensations granted for solid mining. The company contended that when the agreement was made to compensate the men for taking rock from chambers, pillar robbing was not included.

NEILL MAKES ONE RULE FOR ROOM AND RIB WORK

However, the umpire decided that the miners in pillar work were entitled to the same allowances as men working in places which were more difficult to mine. The decision, not being before us, it may be presumed that it was based on the fact that express provision against the application to pillar work was not contained in the rate sheet.

On May 5 the umpire delivered another important decision to the effect that contract miners who were taken off their regular work for an emergency job should be paid the rate called for in their scale if the pay for the other job is less. In this mine, when two miners were pulled out to do emergency work, one was regarded as a miner and paid miner's wages and the other as a laborer and paid laborer's wages.

The umpire, however, made an altogether different ruling about those men who were called upon to perform laborers' duties in clearing away rock which fell in their own chambers. The contract miners of the Harwood Coal Co., whose scale was $3.30 per day, were paid only $2.68 for laborer's work and sought the difference; but this was denied them by the umpire. It may be pointed out that the work in question naturally fell to them. They were not chosen for the work by the company, and it was clearly one they were doing on their own behoof.

UMPIRE NOT A SHIELD FOR INCOMPETENT MEN

Mine workers cannot be expected to be reinstated in their jobs if the operators can show that they were discharged for incompetency, ruled Charles P. Neill, on May 8, in dismissing the complaint of Henry C. Singley against the Evans Colliery Co., of Beaver Meadow. Singley claimed he was promised $100 a month, but did not get the extra war allowance. The company proved that it had placed Singley in another position to that originally provided for him because he lacked experience for the job for which he had been hired, that he was finally dismissed, although paid his $100 wages while working in a subordinate capacity.

At the Drifton mine of the Lehigh Valley Coal Co. the miners have resumed work, the men being willing to leave the adjustment of the dispute to the officials and the company. On May 7 the Mount Jessup Coal Co.'s employees, to the number of 400, went on strike, leaving only the company men at work. The men claimed that their wages are being reduced, especially the wages of the contract miners. The committee denies that it has any inclination to the notions of the Bolshevists or Industrial Workers of the World. It declares, however, that whereas the wage formerly averaged $6 to $7 per day, with the reduction only $4.76 per day is earned. Torquato Natale and Giovanni Liberante are members of the miners' committee. The colliery affected lies in the storm center of the anthracite region—northern Lackawanna County.

Three hundred employees of the Racket Brook Coal Co. declared a strike on May 7 because the company refused to reinstate a motorman and brakeman who had been discharged.

FRANCOIS MINERS WANT NO RED FLAGS AROUND

Every now and again we see glimpses of the real saneness at heart of the West Virginia mine workers. Their strikes have been bitter, and the violence connected with them has, at times, aroused public apprehension. But the men are true-blue Americans, and revolutionary bolshevism and socialism with their red flags do not meet with any response from them. This was demonstrated on May 1 when some foreigners raised a red flag over their home near the Norwood plant of the Francois Coal Co., near Clarksburg, W. Va.

Patriotic miners were assembling at the company's tipple ready to march on the home of the Socialists when officers arrived and forced the foreigners to surrender the flag, which was torn to shreds. A few soldiers kept watch to see that no other red flags were raised during the day. A recent act of the legislature makes it unlawful for any person to display a red flag or even to have it in his or her possession.

For several days during the first part of May, traffic on the Kanawha River was suspended as a result of the strike among the boatmen. The shipment of coal in barges from a number of points along the Kanawha River was

consequently suspended. The boatmen went on strike because their wages were reduced a matter of $30 a month.

In our issue of Apr. 17, p. 720, appeared an article entitled "Should Binder Figure in Coal Thickness?" In it was described the difficulty in the Elkins field as to whether in arranging payment under the scale the thickness of the binder, which is not coal, should be regarded for the purposes of measurement, as if it really were coal. That difficulty still arouses opposition between the contending parties. The miners regard the binder as part of the coal, while the operators declare that the 5 ft. is for clean coal excluding binder. No agreement has so far been reached.

In Missouri, according to William H. Lewis, who is the State Labor Commissioner, there are approximately 40,000 men out of work. He adds that a large portion of these men belong to the mining industry. That, however, by no means necessarily means coal mining exclusively, for the coal mining industry is supplemented by the mining of lead and zinc. In Illinois, it is reported, 20,000 miners are out of work and 70,000 others are working only two days a week.

Labor Leader Found Guilty of Embezzlement

Emmet Moore, who had been entrusted with the funds of the local union of the Macon (Mo.) mine workers, admitted at his trial that he was short $5000 as was exhibited when the auditors went over his books. The case was tried before Judge Drain in the circuit court. Mr. Moore asked the court to allow him a few weeks to work in the mine, so that he could lay up enough money to take care of his wife and two children while serving his time.

Judge Drain allowed him until June to work in this manner, when a penitentiary term of probably five years will be passed on him. Moore has the sympathy of the men from whom he embezzled the money, as he comes of a family which now holds and will retain their respect.

The strike of the 6000 mine workers of the Central Coal and Coke Co. was settled on Apr. 26. Mr. Taylor announced that the trouble was an outgrowth of a change in the time for operating the cutting machines. Because of certain technical difficulties, the company contended that the cutting-machine force should start two hours later than the loading shift. The miners agreed that if both shifts started simultaneously, as they demanded, they would guarantee that the technical difficulty would be removed. It was so agreed.

Mr. Taylor remarks: "Dr. H. A. Garfield sent John L. Lewis, vice president of the United Mine Workers of America, here to confer with Alexander Howat, president of District No. 14 (Kansas), and John Wilkinson, president of District No. 21 (Oklahoma, Arkansas and Texas). He arrived here Tuesday (Apr. 22). I, as representing the Central Coal and Coke Co., entered the conference yesterday (Apr. 25) and this morning we reached an agreement. I submitted the understanding by long-distance telephone to Doctor Garfield, and he approved it, and in consequence the miners will return to work Monday morning (Apr. 28)."

Claim That Safety Powder Is a Handicap

But another strike is threatened in Oklahoma as a result of a dispute about the wage scale in the Hartshorne district. It is claimed that the "safety powder" used in some of the mines will not permit the men to produce as much coal as black powder. In some instances where safety powder is used the operators have raised the wage scale to make up for the decreased output per man. In the Hartshorne district no allowance is made for this. Secretary Eugene Ross is said to have remarked that the strike would not be called until President John Wilkinson, who is on a speaking tour, returns and fully investigates the grievances.

In our issue of May 1, p. 723, is recorded a mysterious strike in the Linton (Ind.) district, which resulted in the calling out of the militia and the declaration of martial law. It appears that into Linton were introduced some eight strike-breaking telephone girls to operate the switchboards of the Linton Telephone Exchange. The local Central Labor Union was believed to be taking steps to deport the girls.

A company of militia was brought to Linton from Terre Haute to take charge of the situation. Under orders of Governor Goodrich the town was given over into the charge and control of the military authorities.

When several hundred coal miners remained away from work on Apr. 29 Federal officials, fearing trouble, ordered another company of militia from Bloomington. Later the Evansville militia was ordered to aid the Terre Haute, Bloomington and Sullivan companies. Adjutant-General Smith also sent orders to Rockville for the mobilization of the militia at that place.

Some persons declared to General Smith that the miners had obtained a supply of rifles and ammunition and also had secreted whiskey which for martial weapons acts as a sure primer. This information made the officials anxious to have sufficient force on hand to insure order.

The Western Coal Operators' Association, by W. F. McNeill, their secretary, submitted a petition before the Federal Industrial Commission of Canada requesting an impartial board to deal effectively with the coal industry in the Western provinces of the Dominion. The operators backed up the secretary by the testimony of John Shanks, manager of the Brazeau Collieries; Jesse Gouge, coal operator of Drumheller, and W. S. Henderson, another operator of the same field. Mr. Henderson was quite willing to see nationalization of mines rather than an extension of the present chaotic condition, blaming the large foreign element for the frequent labor disturbances. The operators testified at length to the excellent accommodations afforded the mine workers—a long story requiring separate treatment, which will later be accorded it.

On Apr. 29 seven coal-owning peers of Great Britain began their testimony before the Government commission, Robert Smillie, president of the Miners' Federation, being the interlocutor. The commission is considering the question of nationalization of the mines and the large holdings of the coal land, the property of these peers, will be under inquiry. Among the peers are the Dukes of Hamilton and Northumberland, the Marquis of Londonderry, the Earl of Durham and Baron Dynevor.

Object to Any Wage Decrease

The men of the Clinton, Ind., field recently assembled in mass meeting and showed clearly their intention to back up the officials of their district and the international officials in the stand those officers intend to make against a reduction in wage. They believe an attempt may be made to reduce wages when the joint convention meets at the close of the war.

At the meeting Edward Stewart, the president of District No. 11, Secretary Mitch and Legal Counsel Harold Henderson of Terre Haute addressed the large crowd present, Board Member Jack Grange presiding.

President Stewart explained that many big users of coal are not stocking fuel as in the past, because they hope to buy cheaper coal after peace comes. These big coal users seem to expect that the operators will make an effort to reduce labor prices which were raised during the war to keep up with the high cost of living. But the mine workers announced during the war that they would not stand for any reduction, and they are sure that there is now no division in sentiment relative to that resolve. What they already have they are fully determined to keep.

Secretary Mitch declared that radicalism is much more justifiable in Russia than in the United States or Great Britain for laboring men are organized in these countries and can through these unions and the ballot protect their interests. He declared he did not believe many of the stories about the Russian bolshevists and thought a little radicalism did good, but he urged the laboring men of America to seek advancement of their living conditions by orderly, but persistent, progress.

Henderson declared that the legal department cost the mine worker only 10c. a month and was well justified because it resulted in better settlements. He urged the mine workers to refuse to sign any compensation papers unless so directed by the mine inspector, coroner or grand jury.

Over the Hills to the Poor House

In three months the United States Railroad Administration has accumulated a deficit of $192,000,000, which is equal to $768,000,000 a year—about three-quarters of a billion dollars. This is more than the United States Government expended during 1916 for all lines of its work, excluding the postal service.

To put it another way, the loss in running the railroads is more than the whole cost of running the United States Government before the United States entered the war. If the Government took over all industries and they were no more unfortunate than the railroads, the loss would be about 12 billions of dollars a year.

DISCUSSION BY READERS

EDITED BY JAMES T. BEARD

Firebossess as State Officials

Letter No. 4—Regarding the suggestion of Robert A. Marshall, *Coal Age*, Mar. 20, p 544, that the firebosses in a mine should be employed by the state, permit me to say that such a proposition must always be considered in connection with the state mining laws. It is reasonable to think that, whatever changes are to be made in the function of any official, such changes must conform with the requirements of the law, which may need to be amended in that respect.

Accepting the mining law of a state as unalterable, however, and as representing the standard of perfection required for the safe and efficient operation of the mines, the fulfillment of its requirements by a fireboss or other mine official will depend on his faithfulness and efficiency, which, in my opinion, will not be affected in any way, whatever the source of the official's authority.

Firebosses appointed by the state and firebosses appointed by mine operators are firebosses still, and are charged with whatever duties regarding the safety of the mine the law may require. A faithful and efficient fireboss will perform those duties with equal sincerity of purpose whether he is employed by the company or the state.

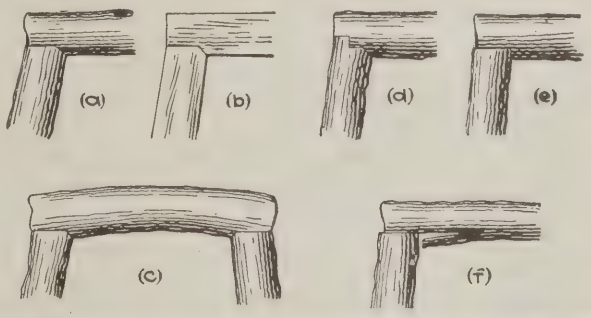
EMPLOYMENT BY THE STATE NOT PRACTICABLE

In the opinion of many firebosses, no doubt, their work could be more effectively performed if they were enabled to act under the authority of the state. But, the fact is overlooked that, under the prevailing operation of mines by private ownership, such a division of authority is impracticable. The fact is also overlooked that, if employed by the state, the function of firebossing would practically cease, as that official would then be acting virtually as an assistant to the mine inspector.

It appears to me that the employment of firebosses by the state would call for a similar employment, by the state, of all mine managers (foremen) and overmen (assistant foremen). This would mean, practically, the placing of our mines under state control.

By the present system, a fireboss is the "competent person" appointed by his employer, the mine operator, to carry out certain requirements of the mining law. Both the employer and the fireboss are then directly responsible to the state for the proper discharge of the latter's duties. The fireboss is simply a mine official acting under the authority of the state law and assisting the management in complying with the law.

On the other hand, as a state official, the fireboss would be the "competent person" appointed by the state to see that the requirements of the law were fulfilled in the operation of the mine. The state and the fireboss would then be directly responsible for the safe operation of the mine.



In conclusion, let me say that my contention is that the position of any mine official cannot be considered intelligently apart from the mining law under which he is acting, and I hold with Mr. Marshall's opinion that a fireboss should not be considered in any other capacity than that of a mine examiner.

Ladysmith, B. C., Canada. W. WESNEDGE.

Safety in Mine Timbering

Letter No. 1—I was much interested in the short article of Joseph R. Thomas, illustrating the right and wrong method of timbering in mines, *Coal Age*, Feb. 20, p. 349. I quite agree with Mr. Thomas that wrong methods of timbering have been the cause of many mine accidents resulting in great loss of life. On this account, there is growing need of more experience in the proper method of notching the collars and framing the legs to fit these notches in a timber set.

Referring to the illustration giving the right and wrong methods of notching timbers, in Mr. Thomas' article, permit me to say that I cannot agree with him that his Fig. 1, page 349, is a proper form of notch, as it does not give opportunity to develop the full strength of the timbers. In the accompanying figure, I have

RIGHT AND WRONG METHODS OF NOTCHING TIMBERS

shown the proper form of this notch, which gives a full bearing of the collar on the top of the leg. I like to call this a "slope" or "Welch" notch. The same notch is employed whether the timbers are round or unhewn as at *A*, or square or sawed timbers are used, as shown at *B*.

When it is possible to obtain a curved timber, the arched form of collar shown at *C* will give a greater strength than where a straight collar must be used. Here also I have shown the same form of slope notch just described.

Formerly, some timbermen employed the double notch shown at *D*. This, however, is not as strong as the slope notch, as the collar or crossbeam has to be hewed deeper to fit the second notch. The idea was to give a little greater resistance to side pressure, by providing a second notch.

The square notch shown at *E* is a wrong method of framing the timbers of a set. This form of notch is very apt to result in splitting the collar as shown at *F*. The slope notch first mentioned not only gives greater strength, but acts to prevent the splitting of the collar. To my notion, also, the slope notch is easiest

made and takes less time. In notching timbers, care must be taken to give a true bearing on the top of the leg, in order to develop the full strength of the set.

Terre Haute, Ind. JESSE HAMILTON.

Roof Conditions in Longwall Work

Letter No. 1—I am glad to respond to the invitation to answer further the inquiry of "Sandrock," which appeared in *Coal Age*, Mar. 27, p. 591, and presented the proposition of working a 3-ft. 4-in. coal seam, by longwall. The seam is described as being underlaid with 3 ft. of fireclay, while the roof consisted of 9 in. of hard sandrock overlaid with 3 ft. of soapstone, above which was more sandrock. I wish to give a little of my own experience and offer a few suggestions.

In 1906, I was superintending a mine in Derbyshire, England. The seam was known as the "High Hazel Coal," and the conditions were such as to be practically identical with those mentioned in this inquiry. From the experience gained in that field, I have no hesitation in recommending the use of the longwall system of mining in the present case.

The work should be carried forward in 300-ft. sections, separated by roadways. Each section formed a conveyor face and was kept a few feet in advance of the

SECTION OF LONGWALL CONVEYOR FACE

face next succeeding, so that the entire longwall face represented a series of steps, as I have indicated in the accompanying figure.

In driving the roads, the plan should be to take up the 3 ft. of fireclay underlying the coal and use it in the packs. Also, the roof should be ripped and the 9 in. of hard sandrock taken down and used for building the roadside packwalls, this being splendid material for that purpose. Taking up the 3 ft. of fireclay bottom will not only prevent the heaving of the roadways should the fireclay become wet, but the tracks will thus be lowered a sufficient distance under the loading platform of the conveyor to enable the coal to be loaded at once into the cars standing beneath the platform.

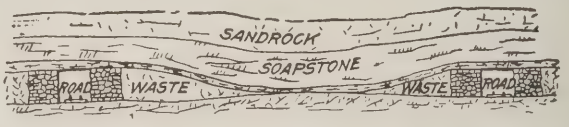
Allow me to suggest, here, that it is a good plan to drive a 20-ft. roadway, at the end of each conveyor face. This will allow ample space for building a good packwall on one side of the track and leaving an air-course behind the packwall, between it and the rib of the next section.

PRECAUTIONS IN TIMBERING A LONGWALL FACE

In order to obtain the best results in controlling the settlement of the roof, there should always be three rows of good props or posts set staggered behind the conveyor, or between it and the waste, as shown in the figure. If the floor is soft, these posts should be set on footboards. No timber should be permitted to remain standing in the waste when the back row of props is moved forward. In no case should the foot of a post be sunk in the fireclay, as that will always make trouble if the fireclay is soft. Should the condition of the soapstone roof be such as to require cogs, these should be built on a bed of slack 10 or 12 in. in thickness, the purpose being to insure the easy removal of the cog timbers as the face advances.

A "Sylvester post-puller," having a long chain, is ideal for this work, as the men doing the job are then well protected from roof falls. If the roof hangs for a considerable time after the back timbers have been withdrawn I would suggest making a good fall, back in the waste, about the middle of the face. For this purpose, it may be necessary to place one or more good shots in the roof.

In the foregoing I have taken it for granted that there is no seam of coal to be worked above the one mentioned. Should that not be the case, however, and it is necessary to provide for the future working of an overlying seam, I would drive a pair of roadways on 42-ft. centers. This plan should also be followed where there is danger of unsteady work, as at the present time.



In the working of the High Hazel Coal, at Derbyshire, we tried a section by driving roadways on 42-ft. centers and building 12-ft. packs on each side of the roadway and ripping the top, instead of lifting bottom as I have suggested here. In that case, the fireclay left in the bottom heaved so badly that the roadways were completely blocked, at intervals of two or three weeks.

Our experience has proved that taking up the fireclay bottom eliminated the danger of the heaving of the floor of the roadway, and the best results were obtained by driving a single roadway at the end of each section or longwall conveyor face. When this bottom was taken up, the water naturally drained from the fireclay in the waste, and there was no heaving to cause any trouble. In the present case, if the plan I have suggested is adopted and superintended by a good man experienced in longwall work, I am convinced that it would be successful. ANDREW ORR BAIN.

McKeesport, Penn.

Letter No. 2—Referring to the proposition presented in the inquiry of "Sandrock," *Coal Age*, Mar. 27, p. 591, allow me to illustrate clearly the condition that is set up in the overlying strata, in longwall work that is properly conducted—a condition that serves to protect the roadways and prevent them from being closed by the settlement of the superincumbent strata on the roadpacks. The closing of the roads is one of the common difficulties encountered in this system of mining.

In order to make my meaning clear, I have drawn the sketch shown in the accompanying figure, which repre-

CROSS-SECTION A SHORT DISTANCE BACK FROM FACE

sents a vertical cross-section taken at right angles to the roadways approaching the face, but sufficiently far back from the face to show the final settlement of the roof on the packs.

It will be observed, as shown in the figure, that as the roof settles down solid on the packs, which must be well built, there is formed a kind of locking action of the roof strata. When this settlement has gone so far that the packs are squeezed into a thoroughly solid mass having almost the solidity of the rock itself, the roadside packs begin to feel the strain. But, at this

point, the locking action of the strata that I have mentioned causes the arching of the strata over the roadways, which protects them from being crushed by the great weight of the overburden.

In the present case, the 9 in. of hard sandrock overlaid with only 3 ft. of soapstone and then more sandrock makes a roof that will be hard to break as it settles on the packs. Certainly, as *Coal Age* has already stated in its reply to this inquiry, it is far better that there should be no break, but that the roof should settle gradually down on the waste. If the packs are well built, however, they will act to cushion the superincumbent weight and cause a gradual settlement, which will generally prevent a sudden break that would not only disturb the roadways but cause other trouble and delay the work.

Danger of Break Occurring in a Longwall Roof

Of course, there would be no objection to a break occurring in the roof, at a great distance back in the waste, where it would not affect the roadways or conditions at the face. However, should this occur, there must be plenty of strong wood chocks to prevent the break from extending to the roadways and the working face.

Stout timbers should be used as posts, the length of a post, in feet, not exceeding its diameter in inches. In other words, the diameter of the post should not be less than one-twelfth of its length.

Where the roof conditions were such that I had reason to fear that a break would occur to damage the workings unless something was done to bring down the roof in the waste, my plan was to drill holes in the roof, at or near the working face, long before such holes had to be shot. The holes should be charged and shot, only when they have receded a sufficient distance back of the timbers, in the waste.

The shooting of these holes would cause a roof fall in that area, which would relieve the pressure on the roadpacks. In closing, however, let me say that such an attempt to break the roof in the waste should never be made if it can be reasonably avoided, as will appear from the evident condition of the roadways and roadpacks. The latter will show when the strain on them is too great, and it is then that it will be necessary to break the roof by some means such as I have mentioned.

W. H. Luxton.

Linton, Ind.

Perils in Reconstruction

Letter No. 7—Speaking of the perils in the work of reconstruction following the great war, these do not appear to me as great as many seem to think. To my mind, they are overbalanced by the opportunities that are now offered to the average citizen in this country. These opportunities were never greater than at the present time.

The presence of such a large number of foreign-born citizens in America is one of the best testimonials to the fact that these appreciate the opportunities offered them. They have come here, primarily, to better themselves, and have found wages, living conditions and opportunities for their improvement so good that they have sent work back home and others have followed them across the great pond.

Because a few young Americans are profligate of their opportunities, live beyond their means and fail to accumulate money or property is no proof that the opportunity to do this is not present. America is, in some degree, a land of wasted opportunities, but these are here and within reach of all who will help themselves. I am glad to say that a large majority of persons living here do accumulate wealth and enjoy the blessings of life and the prosperity that this country offers in greater abundance every year.

Different Types of American Citizens

Let me attempt, briefly, to classify men in three types, respecting the use they make of their opportunities: First, there is the man who enjoys the average degree of health, both of himself and his family. Every young couple who are thus blessed with health can, with reasonable care and industry, quickly save enough to own their own home and accumulate other assets such as Liberty Bonds and stocks in paying investments. If their choice lies in that direction, they can, besides, soon own and enjoy the luxury of an automobile, without indulging in the doubtful experiment of buying it on the installment plan.

A second type of individual is represented by the lavish spender, who is blessed with the same good health and to whom the same opportunities are open of accumulating wealth. Instead, however, of adopting the pay-as-you-go plan, in respect to personal and family expenses, and laying by their small savings until they are able to purchase what they desire without burdening themselves with discouraging debts, this young couple become impatient. At 25 or 30 years of age, they want the same luxuries that their parents were able to enjoy only at the age of 45 or 50. With this class, homes are bought and heavily mortgaged; automobiles are purchased on the installment plan; and these pleasure seekers continue to struggle along under heavy burdens that eat up their small income as fast as it appears. The result is that they become discouraged and their chances for future happiness and contentment are sadly marred.

The Handicap of Ill Health

Finally, there is the third type represented by the man who must struggle along under the incubus of ill-health, either of himself or his family, or both. Truly, this type needs our sympathy. Their small savings are swept away by the expense of doctors' bills, hospital charges, medicines, and other necessities. We can hardly say that the same opportunities for the accumulation of wealth and property are open to this class of unfortunates.

I might mention a fourth type, which, however, is rare. It is represented by the individual who, though not particularly characterized as industrious or saving in his habits, is obviously lucky. Everything seems to turn into money in his hands, not so much because of his ability; it seems to be pure luck or chance. There are, of course, a few far-sighted and exceptionally good business men who manage to accumulate wealth in a few years that other hard working, industrious people are unable to save in a lifetime. It is these exceptional cases of lucky ventures and business ability that give rise to the complaints so often heard of "unequal opportunities."

In striking a general average, the unfortunate, struggling class that I have mentioned are offset by the fortunate and lucky type. But, certainly, the average man and family in America fare well; and it is only a

minor percentage of men who fail to accumulate a reasonable competency whereby they are able to maintain a higher grade of living than is generally possible in other lands.

Let me suggest that young people, and especially young couples, both American-born and foreign-born, starting in life, will do well to think seriously of the opportunities that are before them. All right-minded native and foreign-born citizens alike, I believe, do appreciate these opportunities to a marked degree and refuse to be led by the attempts to malign and underestimate the best country on earth. America is not without her faults, but they are far outweighed by her many virtues. Let us, then, look at the brighter side and cooperate with Uncle Sam to make this country what it ought to be, the chief among the nations.

Clinton, Ind. FOREIGN-BORN CITIZEN.

Letter No. 8—Concerning the future of America, many people are under the impression that, as soon as peace is assured, there will be an exodus of labor from this country that will affect the mining of coal more than any other industry. In this connection, kindly allow me to recite, briefly, a few interviews I have had recently with prominent foreigners in this locality.

On each occasion, I would put the matter squarely before the person, by asking a direct question, the answer to which would reveal the man's attitude in respect to his choice between this country and his homeland. Following are a few of these interviews:

Now that the war is over, if a suitable government were to be established in your own country, the same as that in the United States, would you go back there to spend the remainder of your days?

To this question the common reply was as follows:

I have three, four, five or six children born in this country. They have not only learned the English language, which they speak, but are getting an education here that they could not get if they were to be taken back to where I was born. They would not have, there, the same opportunities that they have here in America.

INHERITANCES OF FOREIGNERS UNCERTAIN

Again, talking with others concerning the land or property that they were likely to fall heir to in the old country, I would ask:

Have you given any serious consideration to the question of going back and taking possession of this property that will be yours?

In answer to this question, the man would invariably reply:

It is true that my father had a large farm before the war, but everything may now be gone. The place is undoubtedly run down; it would require lots of money to start all over again and maybe it would never pay after all. No, we would rather stay in America, because we know that the money we have been able to save here would be largely spent in going back and starting life over again in the old country and, in so doing, we would be deprived of many pleasures that we now enjoy.

Again, speaking of the wage question, I would often ask:

Supposing that your country would offer you wages more than what you receive in this country, and gave you good assurances and inducements to return home, and these assurances appeared good to you, then what?

After some hesitation, the answer would come about as follows:

Well, you see it is like this: The wages and inducements to return might appeal to me and some others; but the most of us would conclude that there are other things to look at and consider. For instance, our children are born here in America. They are growing up and have become attached to this place. Whenever we mention to them anything about going back to the old country, for the purpose of testing their feelings in the matter, they say, "You can go if you will, but we are Americans and will stay here where we were born."

ATTITUDE OF THE FOREIGN-BORN TOWARD BOLSHEVISM

In addition to these personal interviews with many of our foreigners, let me cite further a conversation I overheard between a few foreigners only the other day. They were discussing the form of government proposed by the Bolsheviki element. One of the speakers said with emphasis:

There is no need for such a form of government, as long as wages remain within reason and men can work every day so that they can provide their families with the necessities of life. If capitalists in this country realize, which a good many of them do, that all the working man wants is an honest living, things are bound to move along smoothly. But, once they begin to increase their profits and squeeze the working man, they will sow the seeds of discontent and the two elements will be at loggerheads and strikes and lockouts will follow, which will give Bolshevism a start."

The war has revolutionized the world and capital and labor have coöperated on the same level to win the victory that is ours today. Both of these elements have been brought closer together at terrible costs. If they coöperate now as they did in the war, there will come the time that both will go hand in hand to accomplish whatever they undertake.

As far as the coal-mining industry is concerned, wages appear satisfactory to the majority of the men; but should the attempt be made to lower wages, without a reasonable reduction in the cost of living, we would face a dangerous situation. There are intelligent foreigners who are able to influence and sway their fellow countrymen. It is when these, who are more intelligent, feel rightly that they are hard pressed that the greatest danger arises in respect to labor and its relation to capital. Common sense and feeling for others must prevail in order to secure coöperation and prosperity. LEWIS R. THOMAS.

Edwardsville, Penn.

Efficiency of Mine Officials

Letter No. 9—Since this discussion was started by William Gorman, *Coal Age*, Jan. 16, p. 159, I have been wondering how much of the good advice offered in these letters mine officials will take to themselves. Every mine official from the president down is efficient in his own estimation, and only in the eyes of the close observer is their inefficiency apparent.

While this is a general rule, there are, of course, notable exceptions. Wonder has been expressed that any mine management should select a barber, a store clerk, an accountant or other trade worker to fill a responsible position in the operation of the mine, and mistakes have been made, undoubtedly, at times, in this direction.

It is a trying ordeal for a mine foreman to feel that his boss, the superintendent, is a man with whom he cannot discuss mine matters on a broad practical basis, because of the latter's lack of experience in coal mining. I recall one instance where a clerk was taken from

a store and placed in charge of three mines, as superintendent. On receiving an order for certain supplies for one of the mines, the new superintendent called up the foreman and demanded to know what he was going to do with "cap-pieces." The foreman's explanation of their use in the mine left the superintendent still in doubt as to whether the foreman was not putting one over on him as a joke.

A mine superintendent must know the mining business from A to Z and be able to decide the class of equipment that is best fitted for the conditions with which he has to contend. Most mining men will agree that mine equipment and supplies are the chief factors in producing cheap coal. The proper location of the surface plant, distribution of power, arrangement of tipple and hoisting and haulage systems adopted are other important factors. But *cars, oh, cars!* It is truly disheartening when one thinks of the numberless types of mine cars in use, many of which are ill-adapted to the conditions existing in the mine where they are to be used.

Inspection by an Efficient Superintendent

Perhaps nothing will be more instructive, in this connection, than to follow one efficient superintendent about, on the occasion of his first tour of inspection after taking charge of a mine. Early Monday morning finds him entering the engine room. His cordial greeting is followed by a few direct inquiries, and the engineer explains that "No. 3 boiler was cut out yesterday and found to be so thickly coated with scale as to require much hard work before it can be fired again."

The superintendent remarked that the cost-sheet had informed him of the trouble, and, walking into the boiler room, he at once secured a sample of the scale for analysis. This done, he continued, "Now, John, can you suggest any other trouble here?" The answer came quick, "Yes, our coal is the 'road cleanings,' a mixture of fine coal, bone, slate, sand and clay. We are charged with good coal, but that is what we get, and the cinders that form make it necessary to clean the fires too often to get even fair results."

The superintendent then asked to see the flues, and John opened the door exposing the ends of the boiler tubes and the flues to view. These were found to be thickly coated with soot. In reply to an inquiry, John said the practice was to clean the flues once every two weeks; but promised, hereafter, to clean them twice a week. Further inspection showed steam escaping from leaky pipe joints and valves. In the generator room, sparks were flying from the commutators and the voltmeter indicated from 150 to 175, instead of 250 volts, of all of which the superintendent made mental note and, after a little private talk with the engineer, left the place and proceeded to the tipple.

A Trip Through the Mine

The first thing that caught the superintendent's eye at the shaft head was the wasteful manner of oiling the mine cars as they came out of the mine. Two boys stood, one on each side of the track, and as the cars passed they squirted oil at the car wheels. The rails and timbers were literally smeared with oil. He did not linger here, however; but, calling for a lamp and empty cage, was lowered to the shaft bottom where he found the foreman waiting for him. His greeting was, "Hello, James, how are you? You said something about poor ventilation and I want to see what is the matter."

Passing through a door at the shaft bottom, on the way to the air shaft, the superintendent noticed that the door was poorly hung and that it swung the wrong way so that it leaked much air. Further on, passing up the main airway, stoppings were observed that were poorly built and also leaked air. Breakthroughs were small and obstructed with loose coal, and tool boxes often stood in them. Canvas curtains were used to deflect the air, instead of doors. The result was that, practically no air reached the face.

But ventilation was not the only thing that interested this observant superintendent, on his first tour of the mine. Waste of supplies and material was evident everywhere. Rails, props, ties, boards, canvas, spikes and nails were scattered here and there along the entry. Reaching a place where the men were drawing pillars, rails were seen partly buried under a fall of rock.

At another place, workmen were busy tearing up rails, leaving the spikes where they were drawn. James explained that they would go back later and pick them up; but the superintendent's suspicions were now fully aroused and he pushed on, going further into this place that had been abandoned. Here he found curved rails, parts of switches, timbers, track ties and spikes, all of which should have been gathered up and used again. In another place, a keg of spikes was found, three-quarters full, standing by the track. James explained that it was the custom to set a keg of spikes around, in that way, where they would be handy.

The Young Foreman Given Another Chance

The foreman, James, was a young man. It was his first position as mine foreman and he had been there but six months. In view of these facts, the superintendent decided to talk matters over with him and give him another chance, believing that he would be able to make him a good foreman. Before leaving the mine, therefore, he took James into his confidence, told him his plan and instructed him to rebuild his doors and stoppings, clean up his airways and remove all obstructions from breakthroughs, besides gathering up all waste material that was scattered about the mine.

One feature that was characteristic of this superintendent was his fairness. He treated all men alike, but referred all their complaints to the foreman. He would not tolerate a news carrier. His foreman was the man on the job. In my opinion, a superintendent's success depends on organization. While he must have a system, it should not be an ironclad rule, not to be broken. Neither should it be too flexible. He must have a complete working plan extending from his office throughout the plant to the trapper boy.

We have all heard of the "white-collar" efficient superintendent. I know one of that type that produced cheap coal for a short time, coming on the job when there was a full supply and plenty of everything needful in stock. During his two years of office, he required little new material. He ran the mine so short of supplies that his foreman was obliged to take rails from one part of the mine for use in other sections where they were needed at once. Tracklayers would spend half a day at a time running through old works with a spikebar and bucket, hunting enough spikes to lay a switch, and spikes were frequently drawn from the main track to help out. These are facts gleaned from my own experience, in charge of mines.

Osceola Mills, Penn. S. D. Hainley.

INQUIRIES OF GENERAL INTEREST

ANSWERED BY JAMES T. BEARD

Working an Old Mine

I am writing to ask for some information and advice in regard to one of the old mines still working in this vicinity. The situation is about as follows:

The coal in this mine is 5½ ft. thick and very soft, so that it is easy to roll off the ribs on the butt entries. Overlying the coal is a tender stone, which varies from 1 in. to 6 ft. in thickness, in different parts of the mine. The roof strata above this stone may vary from 10 ft. to 100 ft. in thickness, while the entire overburden reaching to the surface has an average depth of 1500 feet.

The mine has been opened on an eight-entry system, from which cross-entries were driven to the right and left and butt headings turned off these, parallel to the main heading. This is an old mine and the distance from the entrance to the main butt headings, now working, is about 7 miles, while the distance measured across the mine, from the face of the crossheadings on one side, to the same on the other side of the main entries is about 5 miles.

From time to time, there has been considerable trouble due to the development of a squeeze in the workings. I would like to ask what would be a fair thickness of the barrier pillars that should be left between the butt headings and the main-line entries, for their protection? Also, what thickness of room pillars should be left when driving the rooms off the butt headings? Again, is there any way of stopping the progress of a squeeze that has already started, besides pushing the extraction of coal in that section of the mine where the weight is coming?

In the advance workings of this mine there have developed a few small gas feeders, and I want to ask if there is any danger of an explosion occurring on this account. How much air should be kept in circulation in abandoned workings generating a little gas.

Benham, Ky. STRAWBOSS.

One can form only a general idea of the situation in this mine, from the description given, which would seem to warrant the assumption, however, that there is some danger present that would call for the need of much practical experience and the exercise of good judgment in all future operations. The circulation of air, in every part of the mine, should be sufficient to keep all the working places, roads and travelingways free of gas. Each section should have its own ventilating current or air split.

All abandoned areas must be ventilated thoroughly or sealed with substantial air-tight stoppings. The thickness of barrier pillars flanking the main headings should not be less than 100 ft. Where rooms are driven 6 or 7 yd. wide, under the conditions mentioned, the thickness of the room pillars should not be less than 40 ft., making the room centers about 60 ft. The work should be in charge of an experienced foreman and examined frequently by competent firebosses.

When a squeeze has developed and gained much headway in a mine no amount of timbering can stay its progress, under 1500 ft. of cover. The only remedy to apply is the rapid extraction of pillars and the drawing of all timber that is still standing in adjoining and abandoned areas, so as to cause a good fall of roof. A few shots placed in the roof at chosen points will often prove effective in producing the desired result.

Gangway Driven in a Basin

Kindly give me a little information in regard to the best method of drawing pillars under the following conditions. The main gangway of our mine is driven in the basin of the seam, which pitches north and south, on each side of the gangway, the inclination being from 35 to 45 deg. Rooms have been driven to the pitch on each side of this gangway and extended to the outcrop or drift, which is composed of stones and clay.

Our problem is how to recover every pound of pillar coal possible and use as little timber as will make the work safe. The width of the pillars varies from 15 to 18 ft. and the length from 100 to 135 ft. The thickness of the coal varies from 10 to 16 ft. At times, the coal works very free and, again, it is quite hard. We have used almost too many props and double timbers on the roads, and yet have not been entirely successful in supporting the roof. What we desire is to get the opinion of *Coal Age* and its readers in regard to the best means to employ to recover the largest amount of coal in drawing back the pillars. LUZERNE.

————, Penn.

This inquiry is a fair sample of many that come to *Coal Age*, from correspondents expecting to receive some helpful suggestion or advice, but omitting to give the most essential data affecting the proposition. As a rule, these incomplete inquiries are ignored or sent back with a request for more information that would enable an intelligent answer to be given. We present this proposition, however, just as it has come to us, believing that this will do more to show the need of correspondents stating all the conditions surrounding the case when asking for help.

Before any answer can be given to this inquiry, it must be known what is the depth of cover and character of the strata, overlying the seam, nature of the floor, width of rooms, etc. The inquiry should be accompanied with a sketch showing both the plan of the workings and a cross-section taken at right angles to the gangway.

It is not necessary to state, here, that the mining of coal in a seam varying from 10 to 16 ft. in height and pitching from 35 to 45 deg. is attended with danger, and will require the utmost of skill and experience to insure safety and avoid accidents. We shall be glad to receive any suggestions or information that our practical readers feel disposed to give, in respect to drawing pillars on steep pitches. It will be necessary, however, to assume conditions conforming to mining practice.

EXAMINATION QUESTIONS

ANSWERED BY JAMES T. BEARD

Bituminous (Penn.) Mine Foremen's Examination, Apr. 8-10, 1919

(Selected Questions)

Ques.—What measures would you take to secure the best possible results from a fan, the capacity of which is limited and the demands upon which are close to its capacity?

Ans.—Clean up the airways and remove all obstructions to the flow of air, by enlarging the breakthroughs and crosscuts so that they will have the same sectional area as the airways. Wherever possible, shorten the course of air travel and split the air current wherever this can be done to advantage.

Ques.—In a shaft 300 ft. deep, an entry 7 ft. high and 10 ft. wide is turned off from the bottom. The shaft is full of water and overflowing. What is the pressure per square inch and the total pressure, in short tons, on the face of the entry?

Ans.—The static pressure due to a 300-ft. head of water is $300 \times 0.434 = 130.2$ lb. per sq.in. The total pressure on the face of this entry is therefore $130.2 \times 144\ (7 \times 10) \div 2000 = 656.208$ short tons.

Ques.—What dangers may arise from bituminous coal dust, in dry and dusty, nongaseous mines, and what precautions would you take to insure safety?

Ans.—The dry finely powdered dust of bituminous coal is often highly inflammable and easily ignited when suspended in the mine atmosphere. This is liable to happen when accumulations of dust are allowed to gather at the working face, particularly where the coal is blasted after being mined with machines.

To avoid the danger arising from the ignition of a cloud of dust, all fine coal and dust must be loaded out and not permitted to accumulate in the rooms. Strict regulations must be made and enforced, in regard to blasting. The safest plan is to employ shotfirers who are competent men and whose duties would be to inspect, charge and fire all holes drilled by the miners. The shotfirers should be authorized to refuse to charge and fire such holes as, in their judgment, are unsafe. The work of the shotfirer should be done after all the men have left the mine.

Ques.—In an airway 5 ft. wide at the top, 10 ft. wide at the bottom and 6 ft. high, the anemometer reads 280 ft. per min.; what is the quantity of air passing per minute?

Ans.—The average width of this airway is $\frac{1}{2}(5 + 10) = 7.5$ ft., and its sectional area $6 \times 7.5 = 45$ sq.ft. Then, assuming that the given anemometer reading has been taken in a way to obtain a fair average velocity of the air current, the quantity of air passing in this airway is $45 \times 280 = 12{,}600$ cu.ft. per min.

Ques.—What is the purpose of stoppings and what materials would you use in their construction, in nongaseous mines?

Ans.—The purpose of mine stoppings built in the crosscuts or breakthroughs, in entry pillars, is to prevent the air from short-circuiting at such points and conduct it forward to the last crosscut at the head of the entries. Stoppings are also built in entries or other passageways or airways to close off or seal such openings, in order to prevent the escape of any gases that may be generated in such places.

Stoppings in mines should be built of incombustible material, such as refuse stone or slate, brick or concrete. Temporary stoppings are often constructed of a double wall of slate, having the space between the two walls filled with sand or road dirt to prevent the leakage of air through the stoppings. When well built, this makes a good temporary stopping. The permanent stoppings on the main haulage roads, in a large mine, should be built of brick laid in cement, or concrete.

Ques.—Of two airways, intake and return, which, in your opinion, should be the larger? State fully.

Ans.—When considering ventilation alone, the answer to this question should state that the return airway should always have the larger sectional area, because of the increased volume of the return current, which has a higher temperature and contains varying quantities of gas generated in the workings. The volume of the return current is also expanded somewhat by the relief of the pressure due to the mine resistance, as this pressure is always greater on the intake than on the return airway.

However, there may be conditions to be considered, when driving the main haulage roads and airways in a mine, that would call for a larger sectional area to be provided on the haulage road, to make necessary allowance for the obstruction of the air current by reason of the presence of loaded and empty cars that are constantly being hauled out and into the mine. Also, allowance must generally be made for a safe clearance at the side of the track, on all haulage roads.

Taking these considerations into account, in a mine where haulage is performed on the return airway, there is hardly a doubt but that this airway should have the larger sectional area. This is commonly the case in nongaseous mines. In gaseous mines, it is the usual practice to make the intake airway the haulage road, and, in that case, the sectional area of this airway may require to be equal to if not greater than that of the return airway.

Ques.—What is the capacity of a double-acting plunger pump, if the plunger is 20 inches in diameter, stroke 40 inches, and revolutions per minute 25?

Ans.—The sectional area of the plunger is $0.7854 \times 20^2 = 314.16$ sq.in. Multiplying this by the length of stroke (40 in.) and dividing by the number of cubic inches in a gallon (231) gives for the plunger displacement, each stroke,

$$(314.16 \times 40) \div 231 = 54.4 \text{ gal.}$$

At a speed of 25 r.p.m., a double-acting pump makes 50 strokes per minute, and the plunger displacement is therefore $54.4 \times 50 = 2720$ gal. per min. Then allowing 85 per cent. efficiency at the water-end, the discharge of this pump is $0.85 \times 2720 = 2312$ gal. per minute.

FOREIGN MARKETS AND EXPORT NEWS

EDITED BY ALEX MOSS

Survey of the Export Coal Trade of Great Britain

[British (Government) *Board of Trade Journal*, Mar. 13, 1919.]

The British export coal trade, like all British industries, was for over four years organized entirely for war purposes. Not only was the total production of coal seriously reduced by the enlistment of large numbers of skilled miners, not only were important markets cut off by military operations, but the export trade to such markets as were still open was governed entirely by naval and military considerations. Export to France was increased and the needs of Italy were met as far as shipping facilities permitted. Large shipments of coal were made to naval strategic points. On the other hand, distant markets, like South America, were almost entirely sacrificed.

That past condition of things has now to be reversed. How far that is possible depends upon factors which can be indicated but not measured. Much depends upon the state of Europe within the next few years, upon whether it is disturbed or peaceful. Much depends, too, upon the effective competitive power of those countries, which, owing to the special circumstances of the war, and particularly owing to war prices, have been able to enter markets formerly closed to them. It is unnecessary to emphasize the importance of the coal export trade both in itself and in its relation to general commerce; in bulk it is by far the greatest of British exports, and it enables food and raw materials to be imported at cheap return freights. If it is reduced, general commerce will be proportionately hampered.

It is not the purpose of this article to provide answers to the numerous questions that arise, but to furnish some of the materials necessary for answers. In the various tables that follow, the course of the export trade during the war is shown, and the situation at the beginning is contrasted with that at the end. It will be seen not only how the trade has changed as between countries, but also as between classes of coal, and this will help the estimation of the chances of recovery. The progress of the new exporting countries is also discussed, and, finally, particulars are given of the export coal trade of Germany, the United Kingdom's greatest rival in 1913.

Production and Consumption

The British production and export of coal during the six years, 1913-1918, have been as follows (in long tons):

Year	Production Tons	Export Tons	Bunkers Tons	Left for Home Consumption Tons
1913	287,430,000	73,400,000	21,032,000	192,998,000
1914	265,664,000	59,040,000	18,536,000	188,088,000
1915	253,206,000	43,535,000	13,631,000	196,040,000
1916	256,375,000	38,352,000	12,988,000	205,035,000
1917	248,499,000	34,996,000	10,228,000	203,275,000
1918	227,987,000	31,753,000	8,756,000	187,378,000

It should be noted that coal retained for home consumption includes coal for naval and military purposes as well as coal for industrial and domestic uses. The bunkers on former merchant ships taken by the Admiralty are covered among naval purposes.

The trend of things may be shown by expressing the figures for 1914 and subsequent years in percentages of 1913:

Year	Production Per Cent.	Export Per Cent.	Bunkers Per Cent.	Home Consumption Per Cent.
1913...	100.0	100.0	100.0	100.0
1914...	92.4	80.4	88.1	97.5
1915...	88.1	59.3	64.8	101.6
1916...	89.2	52.2	61.8	106.2
1917...	86.5	47.7	48.6	105.3
1918...	79.3	43.3	41.6	97.1

Coal is also classified for export purposes according to its uses, and the particulars are as follows:

Year	Anthracite Tons	Steam Tons	Gas Tons	Household Tons	Other Sorts Tons
1913	2,976,000	53,619,000	11,528,000	1,770,000	3,507,000
1914	2,389,000	42,634,000	10,080,000	1,490,000	2,447,000
1915	2,227,000	31,151,000	7,275,000	1,041,000	1,841,000
1916	2,000,000	27,890,000	6,469,000	377,000	1,616,000
1917	1,384,000	28,322,000	3,700,000	152,000	1,438,000
1918	1,162,000	26,050,000	3,081,000	149,000	1,311,000

The particulars furnished with regard to production do not permit a comparison to be made with the kinds of coal exported except in the case of anthracite, the production of which was: In 1913, 5,195,000 tons; 1914, 4,719,000 tons; 1915, 4,712,000 tons; 1916, 4,644,000 tons; 1917, 3,799,000 tons; 1918, 3,820,000 tons. The corresponding quantities of anthracite retained for home consumption were: In 1913, 2,219,000 tons; 1914, 2,330,000 tons; 1915, 2,485,000 tons; 1916, 2,644,000 tons; 1917, 2,415,000 tons; 1918, 2,658,000 tons. Up until 1917 the home consumption of anthracite increased, and though there was a falling off in that year the consumption was still higher than in 1913. In 1918 the consumption again showed an increase and was greater than in any of the five preceding years.

Destination of Exports

Exports of coal according to destination are summarized below. (A statement given later in this article presents the figures in greater detail.) These figures do not include either coke or patent fuel exported, items that in certain cases (for example, that of France) represents a notable addition.

Exported to	1913 Tons	1914 Tons	1915 Tons	1916 Tons	1917 Tons	1918 Tons
European allies	33,995,000	28,014,000	25,863,000	25,133,000	24,931,000	22,065,000
Enemy countries	10,436,000	6,330,000	10,000	6,000	40,000	19,000
Neutrals	23,488,000	20,297,000	15,221,000	11,404,000	4,555,000	4,712,000
British possessions	5,481,000	4,399,000	2,441,000	1,809,000	5,470,000	4,957,000
Total	73,400,000	59,040,000	43,535,000	38,352,000	34,996,000	31,753,000
	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.
European allies	46.3	47.4	59.4	65.5	71.2	69.5
Enemy countries	14.2	10.7	.....	.....	0.1	0.1
Neutrals	32.0	34.4	35.0	29.8	13.0	14.8
British possessions	7.5	7.5	5.6	4.7	15.7	15.6
Total	100.0	100.0	100.0	100.0	100.0	100.0

The markets lost on account of military operations—Russia, Belgium, Roumania and the enemy countries—took, in 1913, about 18,717,000 tons; but in 1918 only 128,000 tons were sent to Russia and a small quantity to redeemed Turkish territory. Exports to Portugal fell to one-eighth and exports to Portuguese African colonies to less than one-sixth of the prewar figures. On account of submarine troubles in the Mediterranean, exports of coal to Italy were in 1915 and 1916 only about 60 per cent., and in 1917 and 1918 only 42 to 43 per cent., of the annual prewar exports. Exports to France, Algeria, French African colonies and Tunis formed only 19.7 per cent. of the total coal exports from the United Kingdom in 1913, but rose to over 55 per cent. in 1917 and 1918.

Exports to France were 37 per cent. higher in 1917 than they were in 1913, and even in 1918 they were 29 per cent. higher. The distribution of coal to Algeria and Tunis was notably affected by convoy arrangements in 1917, and the same cause explains the very large increase to French West Africa in that and the following year. The exports to France and French African possessions rose from 14,473,000 tons in 1913 to 19,269,000 tons in 1917, or a 33 per cent. increase; but quite apart from the temporary loss of French mines, the special distribution resulting from war causes will plainly not be reproduced under peace conditions. The case is different with Italy, where normal supplies were reduced through the state of war, though the need for coal had increased. France, Italy and their African possessions took 24,125,000 tons, or 32.9 per cent. of the total British exports of coal in 1913; in 1917 they took 23,410,000 tons, or 66.9 per cent.

Neutral Markets—British Possessions

Trade in 1918 with the countries which were neutral in 1915 was only about one-fifth of what it was in 1913; however, this marked some recovery from 1917, when it was a little less than one-fifth. The trade with all these countries fell off progressively during the war, as military and naval demands increased and shipping difficulties became greater. Exports to Scandinavia were in 1918 only 33 per cent. of the 1913 quantity; to Netherlands and Java, a little over 4 per cent.; to Spain and the Canary Islands, under 12 per cent.; to South America, under 9 per cent.

Exports to British possessions (including Egypt) formed 7.5 per cent. of the total exports of coal from the United Kingdom in 1913; in 1917 they were almost the same in quantity, but 15.7 per cent. of the total. Thy had, however, in 1916 fallen to 1,809,000 tons from the 1913 figure of 5,481,000 tons. The exports to Gibraltar and Malta in 1917 were nearly three times what they had been in 1913 and nearly five times the 1916 figure; exports to Egypt were in 1917 only half their 1913 total, but nearly double that of 1916. Exports to these Mediterranean destinations formed very nearly 83 per cent. of the total exports to British possessions in 1917, and were plainly determined by naval policy. Exports to Canada, West Indies and Falkland Isles also showed increases over 1913, for the same reason. On the other hand, exports to Aden fell from 181,000 tons in 1913 to 23,000 tons in 1917; to India, from 179,000 tons to 7000 tons; and to Ceylon, from 240,000 tons to 13,000 tons. In 1918 exports to India were 1350 tons; to Aden and Ceylon, nil.

This brief review of Great Britain's coal export trade may be summed up by saying that from the outbreak of the war exports were sacrificed to military and naval necessities and to the need of rendering assistance to France and Italy, and this sacrifice was coincident with a loss of nearly three-fifths of the bunkering trade (part of which, however, was made good by an increase in Admiralty requirements), and with a continuous and heavy draft on the quantity "available for home consumption" by the naval and munition authorities.

The prospects of an early recovery of the export trade in coal are affected by many considerations. Until the production of coal approaches the prewar level there will be a competition between home industry and

foreign countries for certain classes of steam coal. The demands of countries subjected to the ravages of war will depend on the rate at which their industries can be restored and their own mines can be put in full effective operation. Political considerations may also affect trade for some years to come. Neutral countries will be able to resume their demands for certain classes of coal, but their requirements in others will depend on the condition of world commerce. Certain expanded exports from the United Kingdom will certainly return to their prewar level, since the expansion depended on naval policy.

A further factor has still to be considered—the entry of the United States into markets from which it was previously practically excluded on account of the greater cost of the American coal. Despite the cessation of war conditions, that footing may still be maintained on account of the increased cost of production of coal in the United Kingdom and the greater expense of operating British ships. The most striking advances in the American coal export trade (other than that to Canada) were in European and South American markets.

The effects of the entry of the United States into the war and of the preoccupation of ships for purposes other than the coal trade are strikingly shown by the heavy decrease of United States exports to Europe in 1916-17, a decline which was accentuated in the following 12 months. Exports to Italy formed 79.2 per cent. of the trade in the two prewar years and 75.8 per cent. in the three following years taken together, although the average annual exports of the latter period were three and a half times those of the former. Comparing 1916-17 with 1912-13 and 1913-14, there does not appear to have been a very abnormal increase in the exports to Italy, and in 1917-18 they fell to 201,000 tons; but this, in turn, may have been due to war conditions.

The increase in exports to South America is more serious. The diversion of British tonnage to other routes and special needs for coal gave the United States coal exporters their opportunity, and in 1916-17 their shipments to South America were four and a half times what they were in 1912-13, while those from the United Kingdom in 1917 were only one-ninth of what they had been in 1913. On the other hand, in 1917-18, when the United States also felt the demand for shipping, exports from that country to Argentina fell to 248,000 tons and those to Brazil to 625,000 tons, while those to Uruguay rose to 109,000 tons. For those three countries together there was thus a fall of 37.4 per cent. compared with the previous year. The return of the diverted British ships to the South American trade will help to restore the balance, but it is plain that strong competition will have to be faced.

Production in South Africa and India—Germany's Trade

The output of coal in South Africa in 1913 was 7,858,000 tons; it rose to 9,775,000 tons in 1917 to meet the special demands for coaling ships at Durban and Delagoa Bay. That particular requirement for ships diverted to the Cape route has now ceased, and the South African coal will have to face the competition of the dearer but better British coal. It is worth noting that, notwithstanding this increase in output, British exports to the Cape rose from 65,000 tons in 1913 to 162,000 tons in 1917, the increase being, of course, due to naval policy; on the other hand, the trade to Mauritius, which had been 40,000 tons in 1913, fell to 1302 tons in 1917, and this trade might well be captured by the South African coal mines.

Exports of coal from British India rose from 722,000 tons in 1913-14 to 829,000 tons in 1916-17. Competition between British and Indian coal seems to threaten only in the Ceylon market. The extent to which India appears to have become self-sufficient during the last five years may also be gaged by the fact that the exports of coal from Japan to British India fell from 180,000 tons in 1913 to 29,000 tons in the first 11 months of 1918.

Chief Foreign Purchasers of British Coal

How far the import coal trade of France and Belgium may be affected by imposing on Germany an obligation to supply coal for a period until the French and Belgian mines are restored it is at present impossible to say, and what may be the effects of any such decision or of any transfer of coal fields on the ability of Germany to supply coal to the Netherlands and elsewhere is equally obscure. The disappearance of the great Russian market, even temporarily, is another enormous factor, but there appears to be no reason to suppose that in the markets where German and British coal formerly met in competition the competitive power of British coal masters will be relatively impaired in the future. The chief foreign purchasers of British coal during the past six years are tabulated at the top of this page.

Finally, the recuperative power of the German coal trade must be taken into account. In 1913 the chief exports from Germany were as follows, those from the United Kingdom being given for comparison:

Exported to	From Germany, Tons	From United Kingdom, Tons
Austria-Hungary	12,153,000	1,057,000
Netherlands	7,218,000	2,018,000
Belgium	5,728,000	2,031,000

Promises Early Relief in Tonnage Situation

Export circles were much interested in the recent statement by H. C. Hoover, Food Administrator, that after July 1 many of the ships now carrying foodstuffs to Europe could be released for export trade. In response to inquiries from its members, the American Manufacturers' Export Association took this matter up with John H. Rosseter, Director of Operations of the United States Shipping Board. Mr. Rosseter, who, it will be recalled, issued a statement several weeks ago promising adequate American shipping facilities within thirty days, again asserts that a more liberal assignment of vessels to commercial trades has not only been accomplished, but that this movement will continue with in-

creasing importance during the present month.

Mr. Rosseter's statement given to the Export Association follows:

"Due to the urgency of earliest possible shipment, it has been necessary for some months past to assign every available ship to the service of the Food Administration. As indicated some weeks since, we confidently expect to pass the peak of this requirement within the next few days. We have now practically reached that point, and during the past week have happily been able to begin a more liberal assignment of vessels to commercial trades. This movement to the support of commercial lines will continue with increasing importance during May, and it is expected that with the return of ships from Europe and new tonnage coming from builders we will be in a position during June to take good care of the commercial berths so long neglected.

"In the same way we hope to be able to provide tonnage for the movement of coal, for which there is a large and insistent foreign demand. As also to provide more tonnage for cotton, which movement has been badly congested and very poorly served during the past sixty days."

American Coal Exports in March

Exports of coal, as reported by the Department of Commerce, for March, 1919, and the figures for March, 1918, as finally revised, are as follows:

(In Tons)

	Mar., 1918	Mar., 1919
Anthracite	397,358	117,805
Bituminous	1,223,137	554,037
Exported to:		
Italy	2,473	17,197
Canada	849,282	352,883
Panama	21,959	5,290
Mexico	13,971	5,429
Cuba	170,087	38,107
Other West Indies	45,213	21,548
Argentina	25,623	8,670
Brazil	27,323	60,296
Chile	None	6,934
Uruguay	5,999	3,660
Other countries	61,207	34,023
Coke	141,213	33,749

Practically the only coal imported originates in Canada. In March, 1918, 118,003 tons were imported. In March of this year, the imports were 68,965 tons.

Important Modifications of Bunker Regulations

As a further modification of the bunker rules and regulations, the War Trade Board announced on May 2 that the issuance of trip bunker licenses to vessels of all flags has been discontinued and that time bunker licenses are now being issued to all vessels regardless of flag, valid until revoked, authorizing such vessels to secure in the United States or its possessions bunker fuel, port, sea and ship's stores in appropriate quantities, whenever said vessels are engaged or about to engage in trade to any part of the world, except Germany and Soviet Russia, unless a permit to trade with said countries is issued by the War Trade Board or by the Inter-Allied Trade Committees at Copenhagen, The Hague, Christiania, or Stockholm, or by the Allied Blockade Committee at London.

The War Trade Board also announced that the execution of Bunker Form B-4, which is an agreement required by Sec. 5 of General Rules No. 1, and Bunker Forms B 5-a and/or B 5-c, which are agreements that vessels will return to the United States, have been discontinued. Furthermore, owners and time charterers of vessels are notified that all outstanding commitments and guarantees previously made by virtue of the execution of said agreements are hereby canceled and released, and all owners and charterers are hereby relieved of any and all their obligations thereunder.

Switzerland during the third quarter of 1918 imported altogether 322,643 metric tons of coal (as against 311,570 tons in the corresponding quarter of 1917), 17,347 tons of lignite (301 tons in 1917), 211,671 tons of coke (191,842 tons in 1917), and 83,217 tons of briquets (as against 116,124 tons in 1917. The bulk of the coal (251,640 tons in 1918), lignite (17,316 tons), coke (196,392 obtained from Germany, and only comparatively small quantities of coal from France (23,915 tons) and Belgium (43,656 tons), and of briquets (83,200 tons) was tons in 1918).

Plans to Export Large Volume of American Coal

Means whereby a large volume of American coal can be exported will be found within the next few weeks, it is believed in Washington. An interdepartmental committee, brought into being by the foreign trade adviser of the State Department, soon will recommend a plan to be followed in this connection. The plan itself already has been drafted and revised carefully by a subcommittee of twenty, which includes the Government's principal coal specialists.

The plan now is ready to be placed before the main committee. It is believed, in view of the painstaking care of the subcommittee, that the plan will be approved in practically the form recommended. The subcommittee declines to discuss or give out any information regarding its recommendations, but it is understood that some opposition from the coal operators is anticipated to a portion of the plan.

The coal industry has not been consulted at this writing, but it is expected that representatives of the industry will be called in before the plan is put in final form.

The Government is in a position to exercise an important control over coal exports through its control of shipping. The operators are without official information as to the work of the interdepartmental committee, but their representatives in Washington are a unit in declaring that they are willing to coöperate in any way that will allow exporting to begin. Their aim is to eliminate the present stagnation in the industry by exporting the largest possible volume of coal. There is no tendency to quibble over details. All they want is ships. Once the tonnage is assured, there will be no delay in forming the export association, it is declared.

Foreign Freight Rates

W. W. Battle & Co.'s coal trade freight report under date of May 12, states that the Shipping Board at the present time allows American shippers to charter foreign steamers to carry coal from United States ports to ports on the East Coast of South America on rates, and that this decision may enable American shippers to regain some of the Argentine coal business, which they recently lost.

There are a number of sailing vessels offered for coals to East Coast South American ports at the Chartering Committee's maximum rates, and also a few sailers asking for transatlantic coal. An outside steamer, about 7000 tons coal capacity, was recently offered at $27.50 net form, for coals to Genoa, June loading. Freight market conditions are practicaly the same as a week ago.

The Chartering Committee's rates are as follows:

Steam—Havana, $7.50, 600 tons dis.; Cardenas or Sagua, $9, 300 tons dis.; Cienfuegos, $9, 500 tons dis.; Caibarien, $9.50, 300 tons dis.; Guantanamo, $8.50, 500 tons dis.; $9, 400 tons dis.; Manzanillo, $9.50, 300 tons dis.; Bermuda, $9.50, and Bermuda, p. c. and dis. free, 300 tons dis.; Kingston, $9.50, 400 tons dis.; St. Thomas, $10, 500 tons dis.; St. Lucia, $11, 500 tons dis.; Santiago, $8.50, 500 tons dis.; $9, 400 tons dis.; Barbados, $11, 500 tons dis.; Port of Spain, Trinidad, $11, 500 tons dis.; Curacao, $10.50, free p. c. Curacao, 500 tons discharge. Rio, $19.50 net, 1000 tons dis.; Santos, $19.50 net, 1000 tons dis., or $21 net, 600 tons dis.; Buenos Aires, $18.50 net, 1000 tons dis.; Montevideo, $19.50 net, 750 tons dis.; Pernambuco, $18.50 net, 500 tons dis. Bahia, $18.50 net. To Nitrate Range, $16.50 gross prepaid.

Coal Prices in Germany

The enormous increase in the price of coal in Germany is causing anxiety in industrial circles says Algemeen Handelsblad, of Amsterdam, Netherlands, under date of Mar. 30, 1919. The disorders in the coal industry, the increase in the cost of production due to lack of rolling material, the continued strikes and enormous wage increases granted to the miners along with shorter working hours, have made necessary another large increase of the coal prices, averaging 20 to 30 marks per metric ton. [The par value of the mark is $0.238. At the end of March, 1919, the mark was quoted in neutral markets at about 9 cents.] A comparison with the former prices will show the meaning of these figures. Lump coal, for example, cost 13.50 marks per metric ton before the war. At the beginning of September, 1918, or shortly before the revolution, the price stood at 29.40 marks, or more than double the prewar price. At the beginning of January, 1919, the price was raised to 44 marks. The present quotation is 64 marks, or nearly five times the prewar price. Coke was quoted at 17 marks in July, 1914; at 30 marks in September, 1918; at 58.85 marks in January, 1919; and is now quoted at 88.85 marks. The price of coal briquets has increased from 13.75 to 66.10 marks. If we may believe the mine owners, even these enormous price increases are hardly sufficient to cover the increase in the cost of production.

This assertion may well be true, for the State might have exercised its power of veto and refused its consent to such enormous price increases. The increase in the price of coal will naturally increase the cost of production in all other industries. Price increases have already been announced in the iron industry. The steel syndicate has not taken any steps in this direction as yet but will be compelled to follow, as both of its principal materials—coal and iron—have risen in price. An increase of steel prices will force the machinery industry and kindred branches to raise the prices of their products. The endless screw will thus be tightened still further.

An effort will doubtless be made in Germany to counteract the influence of these higher prices by increasing wages. As this process continually leads to new demands, the ability of the German exporting industries to resume competition in the markets of the world will grow less and less, notwithstanding the advantage which the exporters derive from the depreciation of the mark.

Mining Congress and Export Problems

A meeting of the committee appointed by the Committee on Export of the American Mining Congress met May 9, at 10.30 a. m. in New York City. The session was extended till 1.30 p. m., during which time Allen Walker, of the Guaranty Trust Co., submitted three or four plans that had been adopted by various industries. One of these plans seemed to the committee to be well suited to the needs of the coal industry.

Thomas F. Farrell, who has just been elected chairman of the Foreign Trade Committee of the National Coal Association, commonly known as the Committee of 27, while interested in the plan presented, was not disposed to take any action till his committee had met and declared its point of view in the matter of coöperation with the other members of the American Mining Congress' committee. However, Mr. Farrell made the statement, in the course of the meeting, that he believed a solution of the matter might be found along the lines of the plan submitted by Mr. Walker.

The National Coal Association was represented by Charles S. Allen, who filled the place of G. M. Dexter, then out of town. Mr. Allen expressed himself quite favorable to the plan. Another meeting of the committee will probably be called toward the close of this week, the Committee of 27, which was scheduled to meet May 13, having meantime, doubtless, expressed its attitude in the matter. For the prior action of the American Mining Congress, see page 867 of the issue of May 8.

Brazil's December and January Coal Imports

Vice Consul A. I. Hasskarl, of Rio de Janeiro, reports that coal imports into Brazil in December, 1918, amounted to 48,315 metric tons (1 metric ton = 2204.6 lb.) compared with 51,676 tons in December, 1917, and 38,930 tons in the corresponding month in 1916. Of these shipments, the United States supplied 32,365 tons in 1918, 51,676 tons (the total imports) in 1917, and 37,964 tons in 1916; the remainder was British coal. During January of the present year, 52,357 tons were shipped into Brazil, of which 49,323 tons came from the United States and 3034 tons from the United Kingdom. In the corresponding month in 1918, total imports amounted to 19,552 tons, all from the United States; in 1917, imports totaled 31,102 tons, 29,264 tons coming from the United States and the remainder from the United Kingdom.

COAL AND COKE NEWS

EDITED BY ALEX MOSS

Harrisburg, Penn.

On May 7, a new workmen's compensation bill, which is understood to be agreeable to all forces, was introduced by Senator Smith of Dauphin. The bill was one of four relating to injured employees which were drawn by the Attorney General. They were immediately reported from committee and read for the first time before the session was adjourned.

The compensation measure reduces the period of waiting before compensation begins, from 14 to 10 days. Another provision of the bill provides 60 per cent. of the average salary, fixed at $10 to $20, instead of the present 50 per cent. On the new percentage basis, the minimum compensation would be $6 a week and the maximum $12.

The new measure further provides that the period of free treatment be increased from 14 days to 30. In case of major and minor operations, a sum not to exceed $100 is allowed and an additional amount for hospital treatment.

Another of the bills introduced by Senator Smith provides for the creation of a Bureau of Workmen's Compensation within the Department of Labor and Industry, which leaves the bureau under the Labor Department as heretofore. There has been a movement under way for some time to create a separate department of Workmen's Compensation, but it is evident that it is not the administration's desire to do so at this time.

Another bill provides for the appointment of a Director of Rehabilitation, who shall care for maimed employees in such a way as to make them fit for other work.

The fourth of the bills would license corporations carrying their own compensation insurance. Companies carrying their own insurance would have to pay a sum equivalent to 2 per cent. of the premium paid insurance companies.

Charleston, W. Va.

All signs point to a general recovery from the slump which began the first of January in the central southern coal fields of West Virginia. Production is gradually growing larger, as demand became more pronounced during the closing days of April. The last-named month was somewhat better from the standpoint of production than was true of March. May 1 brought many additional inquiries for coal, indicating a somewhat more buoyant market. As a consequence mine owners not only felt much encouraged over the outlook, but were able in a number of instances to resume operations, thus cutting down the number of idle mines. Indeed, some fields were able to produce up to 65 and 70 per cent. of their normal output.

For several months mine owners have been encouraged with orders that enabled them to run their mines for as much as two days a week. Orders are now sufficient to keep many mines going four days a week. With increased activity in and around West Virginia mines, a labor shortage is beginning to be felt. During the period of idleness covering four months, there has been an exodus of miners from the state, and the general scarcity of labor may prevent as large a production as might be expected even when conditions reach normal again. The car question has not begun to bother operators so far to any appreciable extent, although it is learned that coal is blocked somewhat at certain forwarding junctions, especially insofar as the lake movement is concerned.

The last days of April and the first week of May saw a growth of encouraging proportions in the shipments of coal to the lakes, although the movement to the lake regions was far from being up to that usually observed this late in the year. Still, from some sections, there was five or six times as much coal being shipped to the lakes as was observed at the outset of April, but some districts were faring better in that respect than others. Heavier shipments to tidewater indicated during the first five days of April a larger volume of export business, but West Virginia operators are not optimistic as to the growth of the export trade to large proportions as long as no effort is made to supply sufficient ships. Still there was undoubtedly more export business in April than during March.

The drive made to force down the price paid for railroad fuel was still contributing somewhat to the uncertainty which has done so much to retard a quicker return to normal conditions, and the volume of railroad fuel shipments around the first of May seemed to be somewhat lighter than was true during the last half of April.

Fairmont, W. Va.

Shipments from the Fairmont field, and in fact from all parts of northern West Virginia, during the first six days of May, indicated a healthy revival in the demand for coal from the northern part of the state, both in eastern and western consuming areas, the only fly in the ointment being the low price at which some operators were selling their coal to railroads in the east. Shipments had jumped to 824 cars a day by May 2, the heaviest loading since early in January, on the Monongah division of the Baltimore & Ohio. On the same date more coal was being mined and shipped to Curtis Bay than at any time during the year, some of it for export markets. Even lake shipments continued to grow in volume. There was also apparent an increase in orders for railroad fuel, shipments on May 2 being larger than at any time since the latter part of March. Total shipments for April reached 14,101 cars, or 1586 more cars of coal than were loaded and shipped in March. As the month of May progressed, a steady decrease in the number of idle miners was discernible. Complaint is being made against the Baltimore & Ohio for withholding information as to how much coal it is buying.

George T. Watson, assistant to the president of the Consolidation Coal Co., commenting on present and future conditions in the industry, predicts that there will be an acute car shortage within the next few months unless steps are taken by the railroads to renew their equipment or unless new equipment is added. He is of the opinion that the next few months will witness unexampled activity in the coal trade.

George T. Bell, executive vice president of the northern West Virginia Operators' Association, has advised members of the association that he has learned that the present practice of railroad fuel agents asking bidders on railroad fuel to revise their bids or to submit new bids after the bids are supposed to have been closed, is admittedly followed for the express purpose of obtaining lower bids.

Du Quoin, Ill.

Current reports state that the Chicago, Burlington & Quincy R.R. is planning to increase its equipment and storage yards in Williamson and Franklin Counties in order to make more room for handling coal from Herrin, West Frankfort and Christopher. It has purchased 2500 acres of land near Cambon and intends to sink a large mine at that place and also erect a roundhouse with better water facilities to supply the locomotives in that district.

A new coöperative store has been opened in this city by the local unions of the miners employed at the Security, Paradise and Majestic mines, with J. W. Gibson as store manager. The coöperative store idea has become popular among the miners of southern Illinois, and a number of these stores have been started in an attempt to reduce the high cost of living.

Announcement has been made by State Mine Inspector Frank Rossbottom that the conference between miners' representatives, operators and school authorities, which was to be held in this city Friday, May 9, for the purpose of discussing "vocational education" for the miners, has been postponed until June 6.

PENNSYLVANIA

Anthracite

Jermyn—The large breaker of the Delaware & Hudson colliery here was closed on May 2 for an indefinite period. It was stated that mining operations will continue at the colliery and that coal will be sent to the Powderly breaker at South Carbondale. It is believed that the Jermyn breaker will be abandoned.

Lykens—Announcement was made on May 7 that the Susquehanna Collieries Co.'s offer to sell its Lykens Valley holdings rather than submit to an increased assessment had been withdrawn with the expiration of the month of April. Officials said that they would still consider an offer to sell if a purchaser turns up.

Honesdale—The Howard Coal Co. has sold its holdings in the large culm dump along the old Gravity roadbed to P. J. McDonald, of Scranton, who has been working it on the royalty basis for some time. It is estimated that there are over 100,000 tons of coal in the pile. The consideration is said to have been $50,000.

Carbondale—It is reported that the Tip Top Coal Co. has voluntarily ceased mining operations on the mine fire tract in this city, and that the breaker and other equipment is now being removed from the property. The lessee of the tract, George W. Tappan, concluded to cease operations, it is said, after the city filed the petition asking for an injunction to restrain him from further mining on the tract.

Minersville—The Pine Hill Coal Co. has started to clean out Wolf Creek in accordance with its agreement with the borough officials, and other coal companies of the region will coöperate at once. These corporations have agreed to clean out the streams, as the culm has swept over Minersville, seriously blocking sewers and drains and even backing water from the sewers back into the houses, creating a most unsanitary condition.

Hazleton—Mine Foreman Adam Lesser and his assistant, John Hurley, of the Upper Lehigh colliery, claim that they have smashed to smithereens the record of Harry Lewis, of the Primrose mines of the Lehigh Valley Coal Co., whose feat in running a slope for five years without a single fatality has been given wide publicity. In the 25 years that both men have been in charge at Upper Lehigh, that colliery has had just two fatal accidents. In that time the mines produced 2,880,000 tons of coal, or 1,440,000 tons per fatality.

Hazleton—The Hazleton and Mahanoy Division of the Lehigh Valley R.R. reports that coal tonnage traffic during April had climbed to between 65 and 70 per cent. of the volume handled during the war and severe winter rush of last year. This is about the maximum, inasmuch as the stripping and culm bank sources of supply that ran totals so high last year are now almost depleted. The railroaders are getting steady employment and the outlook for work all summer, both on the coal division and in the mines, is excellent.

Pittston—An unusual case, growing out of the sale of four acres of coal land in 1882, on which suit was started in 1911, has just been decided by Judge Fuller (Luzerne) in the suit of the executors of Theodore Strong, late of Pittston, against Abram Nesbitt, of Kingston, in which the court sustains the exceptions to the report of the referee and enters judgment for the defendant. Apart from the fact that it is over 37 years since the coal was sold and eight years since the suit was started, the proceedings reveal the value of the coal from the fact that although only $2411 was paid originally the plaintiff received $9601 in royalties. The case was highly complicated. It seems that the four acres of coal land sold under a certified road, the title of which Mr. Nesbitt had obtained through a patent from the Commonwealth, and he had what was con-

sidered a good title until the decision of the Supreme Court in 1898, when it was decided that certified roads were not exempt from the general rule that abutting property owners owned to the center of the highway. At this time Mr. Strong had leased the coal to the Delaware, Lackawanna & Western Railroad Co., but by the decision of the company itself became the owner of the coal because it owned the abutting property. Then the executors of the Strong estate brought suit to recover the money originally paid and were awarded the full amount by the referee, with interest amounting to $7612.

Pottsville—This is the richest coal city, not only in the United States, but in the whole world, according to a report made by W. C. Monroe and W. F. Sekol. These engineers stated that there is 80,000,000 tons of coal under Pottsville, in well authenticated veins, the coal being more than 200 ft. in thickness. It is premium quality, much of it being of the famous Lykens Valley red ash. There are 22 veins above the Mammoth and four veins below. More than this, Sekol and Monroe stated that Pottsville is the center of the great anthracite basin and that of the 53 billion tons of coal remaining unmined in this region, 41 billions are in this section.

Freeport—The Beal Coal Co. will build an up-to-date tipple this summer at its new mine now being opened at this place. The tipple will have a capacity of 600 tons a day.

Bituminous

Indiana—The Coal Run Mining Co. has moved its general offices from the Elwood Building, Rochester, N. Y., to the Savings and Trust Building here. Among the officials to be transferred are John O'Connor, treasurer, and L. W. Robinson, Jr., general manager.

Uniontown—There has been no noticeable improvement in work in the Connellsville coke region the past week, though a few small accumulations seem to have been disposed of at a reduced price. In the central and western Pennsylvania bituminous fields there has been considerable improvement, due partly to the Lake trade.

Brownsville—Following the strike at the mines of the Vesta Coal Co., when the men decided to return to work the mines were closed down by the company and are now idle. This company is a subsidiary of the Jones & Laughlins Steel Co.

The H. C. Frick Coke Co. has closed down the ovens at its Buffington and Footedale coke plants. It is rumored that this company will close all its operations for sixty days.

Pittsburgh—On Monday, May 5, at the annual meeting of the stockholders of the United Coal Corporation, the proposition from the J. H. Hillman Sons Co. for the mutual operation of the properties of the former company and other operations, and the change of the name of said company to the Hillman Coal and Coke Co. was acted upon favorably, the change to be effective June 1. J. H. Hillman, Jr., president of the Hecla Coal and Coke Co. and the Thompson-Connellsville Coke Co., was elected chairman of the Board of Directors, and T. W. Guthrie, president of the United Coal Corporation, was elected president. What changes, if any, will be made in the operating personnel has not yet been announced.

Waynesburg—In addition to the sales and transfers of coal land recorded on p. 885 of the May 8 issue of *Coal Age* are the following sales of coal land to the Cumberland Coal Co.: J. R. Nutt, Cleveland, Ohio, eight tracts in Whiteley township, consideration, $292,308.40. T. B. Seamans, Uniontown, one-seventh interest in six tracts in Cumberland and Monongahela townships, 562.46 acres; consideration, $62,-104.12; G. S. Harah, Uniontown, one-seventh interest in nine tracts in Cumberland and Jefferson townships, 595,716 acres; consideration, $42,456. Chalissa Roberts, one-eighth interest in a tract in Cumberland township, 24 acres; consideration, $1. Carl C. Minor, one-eighth interest in tract in Cumberland township, 59 acres; consideration, $1. Arley W. Kisinger, one-eighth interest in tract in Cumberland township, 158 acres; consideration, $13,833.21. Thomas W. Wright, one-eighth interest in a tract in Cumberland township, 9.19 acres; consideration, $1. Other transfers to the Cumberland Coal Co. include Charles H. Jordan, coal underlying a lot in Jefferson borough; consideration, $250; Susan V. Young, one-half interest in 181 acres, Greene township; consideration, $64,751.75. Irving H. Cottom, of Fayette County, has sold an undivided 25-1767th interest in 16 tracts in Richhill township to Harry A. Cottom, of Brownsville; consideration, $3000.

WEST VIRGINIA

Huntington—A loss of $50,000 was sustained by the Island Creek Coal Co. at its No. 2 plant at Holden recently, when the tipple at that mine was destroyed by fire. It is the intention of the company to rebuild the tipple without any delay. A. R. Beisel is the president of the Island Creek Company.

Whipple—The New River Coal Co. is understood to be arranging plans for the erection of new coal tipples at its properties at Whipple, Lochgelly and Summerlee. At the present time the company has a daily production of about 12,000 tons.

Bluefield—The Coalwood plant of the Carter Coal Co. is to be the scene of numerous improvements during the summer months, plans being now under consideration for the erection of a steel tipple and automatic hoist as well as for the construction of a number of dwellings for miners. The shaft at which the tipple is to be built constitutes the entrance to about 1900 acres of coal.

Macdonald—Full speed ahead are the orders at all the operations of the New River Co.—15 in all—in Fayette and Raleigh Counties, and as a result the company is getting out about 12,000 tons of coal a day. Orders on hand will make it possible to operate on a full-time basis for the next month, and by that time it is believed further orders will enable the company to keep its mines on a full-time basis indefinitely.

Charleston—A deal of as large a magnitude as has been recorded in this section in some time was that through which the General Underwriters, Inc., acquired the control of the Penn-Virginia Coal and Coke Co.'s holdings of the Black Band Fuel Co. for $100,000. The purchase includes leases for coal, oil and gas to the Paint Creek Collieries Co. and the South Penn Oil Co., 500 shares of Kanawha Central R.R. stock at the par value of $100, together with the mining equipment, etc. It is regarded as certain that under the new ownership there will be extensive development of the Black Band property in the future.

Huntington—Further impetus was given to production in the Logan field at the beginning of May through a continued increase in lake orders, the total increase being 7000 tons, the coal loaded ascending from 131,000 to 138,000 tons, bringing the ratio of production up to nearly 50 per cent., or, to be exact, 46 per cent., as against 38 per cent. for the previous week. There was a most pronounced reduction in the total production loss from 211,000 tons to 162,000 tons, or a difference of 49,000 tons. Still, as might have been expected, the "no market" loss was still running high —144,000 tons. Other sources of production loss did not amount to more than 5 per cent. That production is still far below normal is shown by the fact that at this time last year the output was at the rate of 200,000 tons a week—a difference of 62,000 tons.

Clarksburg—The Corons Coal Co., successor to the Commercial Coal and Coke Co., has purchased from Floraneus Reynolds' estate at Hepzibah a tract of approximately 100 acres adjoining the tracts of the Short Line R.R. The consideration was $20,000. Much of the land is underlaid with a fine grade of Pittsburgh coal. The company already owns considerable mineral rights in the tract in question and has a mine in operation.

INDIANA

Petersburg—Following the orders for a strike at the Muren mines, south of this city, on the Southern R.R., the Muren Coal Co. has ordered its mines closed down for three months. The Muren company has turned its contracts over to the Ayrshire Coal Co. and has closed its general store until the mine reopens for business. The miners employed by the Muren company struck following a disagreement over petty matters.

Indianapolis—An increase of 25c a ton in the price of Pocahontas shoveled lump has been announced by the Indianapolis coal dealers, making the price $8.25. According to the principal dealers, this is the only grade affected and no further changes in coal prices are likely during the remainder of the summer. At the beginning of April some dealers were charging $7.75 for Pocahontas shoveled lump and some $8. Those charging the $7.75 advanced to $8 and the added advance to $8.25 is now uniform with all the larger companies. To offset this, the summer price of coke is $9.75 a ton as compared to $12 a ton during the winter months.

ILLINOIS

Buckner—A disastrous accident in which one man was killed and three were seriously injured, happened at the Old Ben Coal Corporation mine at this place late Saturday night, May 3. John L. Devot was instantly killed and William Grean, Leslie Greyhouse and Edward Clark were the injured. The four men were ascending on the cage when the engineer seemed to lose control of the levers and hoisted the cage up into the sheave wheels. Devot fell back down the shaft, which was over 600 ft. deep, and the other three men escaped death by falling into the coal chute.

Royalton—The north mine of the Franklin Coal and Coke Co. broke its record last week when 3947 tons of coal were hoisted in eight hours. During the day 1470 pit cars were hoisted. Following the day's work the company gave a banquet to all of the employees of the mine.

Harrisburg—The O'Gara mine No. 12, which is one of the chain of mines controlled by the O'Gara Coal Co., of Chicago, has received orders to close down for an indefinite period. No reason is stated for this order.

Westwood—The U. S. Fuel Co. is planning the erection of a new modern steel tipple at its Vermillion mine at this place. It is expected that the structure will be completed before the end of the year.

Benton—The project of creating a network of electric lines in Franklin, Williamson and Saline Counties, comprising the southern Illinois coal belt, is being revived. It was checked by the war. Before the war, W. H. Schott, of New York, was instrumental in having lines built connecting Eldorado, Harrisburg and Carrier Mills. Extensions were projected to Marion, White Ash, Johnston City, West Frankfort and Benton. It is stated that the revived project will include Christopher, Herrin, Buckner, Ziegler, Royalton and Hurst, and back to Marion, completing a loop of all the principal cities in the coal belt. The lines would touch about 60 mines and would provide transportation for the miners and additional outlets for the coal.

New Douglas—The Madison County Mining Co. announces that it has struck a 7½-ft. seam of excellent coal near here. The seam is believed to be the same as that at Sorento, Ill.

Benton—The Franklin County Mine Examiners' Association has been organized for the purpose of systematizing the work of the examiners and of securing reforms in the mining industry tending to make conditions in the collieries safer to all employees.

WASHINGTON

Mendota—The Mendota Coal Co. is understood to have completed arrangements for the electrification of its local coal-mining properties. The proposed installation calls for a 100-kw. engine-driven generator, 440-volts, three-phase, and approximately 100 horsepower in motors for the operation of the hoist, fans, pumping machinery and other apparatus. The company maintains offices at Centralia, with plant at Mendota.

Foreign News

Montreal, Que., Can.—The Century Coal and Coke Co., Ltd., of Montreal; the Quebec Coal and Dock Co., of Quebec; the Toronto Coal and Dock Co., of Sault Ste. Marie; the Colborne Coal and Dock Co., of Port Colborne, and the New Ontario Dock Co., of Sault Ste. Marie, have consolidated under the name of the Century Coal Co., Ltd., of Montreal. The new corporation has an available capital of $2,500,000 and plans extensive alterations and additions to dock and storage facilities.

Personals

Thomas Simpson, of Belleville, Ill., has been elected County Mine Inspector for St. Clair County by the Board of Supervisors.

N. S. White, formerly mine foreman of No. 7 mine of the Anita Coal Mining Co., has been made superintendent of the Horatio mines of that company, at Punxsutawney, Penn.

Capt. J. A. McIntosh, who has been in the service overseas with the tank corps, has returned to his former position in the engineering department of the Ohio Brass Co., Mansfield, Ohio.

T. V. Bush, for many years in charge of the Coal Department of the Chesapeake & Ohio Railway Co., will take charge of traffic matters for the Raleigh Coal and Coke Co., of Cincinnati, Ohio, effective May 15.

C. C. Fenwick, general mine foreman for the Anaconda Copper Mining Co., Coal Department, at Sand Coulee, Mont., has severed his connections with that company to take charge of the Darby Coal Co.'s works at Darby, Mont.

James Biers has resigned as superintendent of the Horatio mines of the Anita Coal Mining Co. at Punxsutawney, Penn., to become representative for the Hulburt Oil and Grease Co. Mr. Biers' headquarters will be at Indiana, Penn.

John Vose, Sr., has resigned as mine superintendent of the Sangamon mine of the Wilcoxson Coal and Coke Co., of Chicago, Ill., after continuous service of 31 years. Mr. Vose is the oldest mine superintendent in point of service in the State of Illinois.

T. J. Dawson, formerly in charge of the Department of Mines of the Superior Pocahontas Coal Co. and the Collins-Mayo Colliery Co., is now general superintendent of the mines of the Raleigh Coal and Coke Co., of Cincinnati, Ohio. Mr. Dawson's headquarters will be at Raleigh, W. Va.

J. C. Hill, formerly of the Car Distribution Department of the Chesapeake & Ohio, at Thurmond, W. Va., and later with the Fuel Administration, at Charleston, W. Va., has recently been placed in charge of shipping at the Raleigh offices of the Raleigh Coal and Coke Co.

W. J. Culleton, superintendent of the Phillips plant of the H. C. Frick Coke Co. at Phillips, Penn., has been promoted to be superintendent of the Ronco and Leckrone plants of the same company with headquarters at Leckrone, Penn. Mr. Culleton has been at the Phillips plant for several years, and is succeeded at this mine by M. A. Burriss, of Footdale, Penn.

J. P. Brennen, president of the Thompson-Connellsville Coke Co., of Uniontown, Penn., has resigned as active head of the corporation. He has been connected with this and other coke companies for the past forty years and has been called "The dean of coke industry in the Connellsville region." Mr. Brennen has not announced his plans for the future, nor has his successor been named.

H. H. Morris, of Huntington, W. Va., has been appointed as a shippers' representative on the Central Territory coal and coke committee of the U. S. Railroad Administration, whose headquarters are in Pittsburgh. This committee fixes the rates on coal and coke from Pennsylvania, Kentucky, Virginia and West Virginia to western points. Mr. Morris heads the West Virginia Standard Coal Co. He is also heavily interested in the Kentucky Elkhorn Byproduct Co. and is a director in the Central Coal Association.

Obituary

Charles Manhart, a widely known mine operator of Galena, Kan., died recently after an activity of twenty years in the Galena mining fields.

T. Ellsworth Davies, prominent as a mining engineer and coal operator, died suddenly at his home on May 7. As a consulting engineer Mr. Davies had been in much demand, besides being the consulting engineer for the county commissioners of several of the anthracite-producing counties.

Coming Meetings

American Wholesale Coal Association will meet on June 3 at Cleveland, Ohio. Secretary, L. Romanski, Chicago, Ill.

Illinois Mining Institute will hold its annual meeting May 22, 23 and 24. Secretary, Martin Bolt, Springfield, Ill.

National Coal Association will meet May 21, 22 and 23, at Congress Hotel, Chicago, Ill. Secretary, J. D. A. Morrow, Washington, D. C.

Illinois and Wisconsin Retail Coal Dealers' Association will meet at Hotel Nelson, Rockford, Ill., June 4 and 5. Secretary, I. L. Runyan, Chicago, Ill.

International Railway Fuel Association will hold its annual meeting May 19-22 at the Hotel Sherman, Chicago, Ill. Secretary, J. G. Crawford, Chicago, Ill.

Retail Coal Dealers' Association of Texas will hold its annual meeting on May 19 and 20 at Fort Worth, Tex. Secretary, C R. Goldman, Dallas, Tex.

Southwestern Interstate Coal Operators' Association will hold its annual meeting June 10 in the Keith and Perry Building, Kansas City, Mo. Secretary, C. N. Fish, Leavenworth, Kan.

American Society of Civil Engineers will hold its forty-ninth annual convention in St. Paul and Minneapolis, Minn., June 17 to 20. Secretary, C. W. Hunt, 33 West 39th St., New York City.

Mine Inspectors' Institute of the United States of America will hold its annual meeting July 8 to 11 at Indianapolis, Ind. Secretary, J. W. Paul, Pittsburgh, Penn.

Kentucky Mining Institute expects to hold its annual meeting this year on May 30 and 31 at Lexington, Ky. Secretary, C. W. Strickland, Huntington, W. Va.

American Institute of Mining and Metallurgical Engineers will hold its fall meeting Sept. 22 to 26 in Chicago, Ill. Chairman Chicago meeting, Carl Scholz, 547 West Jackson Boulevard, Chicago, Ill.

American Society of Mechanical Engineers will hold its spring meeting at the Hotel Statler, Detroit, Mich., June 16 to 19. Secretary, Calvin W. Rice, 29 West 39th Street, New York City.

American Institute of Electrical Engineers will hold its annual convention at the Lake Placid Club, Adirondacks, N. Y., June 24 to 27. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

Industrial News

Chicago, Ill.—The Fischer & Hayes Rope and Steel Co., manufacturers of wire rope, manila rope and accessories, have moved to 741-745 West Van Buren Street.

Knoxville, Tenn.—The Coalfield Coal Co., Knoxville, plans to start work shortly on rebuilding its burned tipple and coal-handling plant. C. W. Henderson is treasurer of the company.

Nevo, Ky.—The Rose Creek Coal and Coke Co. has recently filed notice with the Secretary of State of an increase in its capitalization from $20,000 to $100,000, to provide for general business expansion.

Lexington, W. Va.—The Perkins Coal Co. has been incorporated with a capital of $25,000 to engage in the development of coal properties in the Lexington district. J. E. Strickler is the principal incorporator.

Chicago, Ill.—L. V. Este, Incorporated, industrial engineers and accountants, for a number of years located in the McCormick Building, have removed their office to the Century Building, 202 South State St.

Providence, Ky.—The Pluto Coal Co. has been incorporated with a capital of $50,000 to engage in the development of coal properties in the Providence section. W. Scroggins, Andrew Bogg and S. C. Turner are the incorporators.

Birmingham, Ala.—The Kershaw Mining Co. has been incorporated with a capital of $50,000 to engage in general coal-mining operations in Walker County. C. G. Kershaw is president and T. M. Porterfield is secretary-treasurer.

Chicago, Ill.—The American Steam Conveyor Corporation announces the appointment of N. B. Stewart as district representative in charge of the St. Louis territory. Offices have been opened at 708 Merchants-LaClede Building, St. Louis.

Nashville, Tenn.—The Nashville Retail Coal Dealers' Association has been incorporated under the general welfare laws of the State of Tennessee. Fred B. Cassetty, H. H. Perry, J. L. Hales, A. J. Lucas, H. M. Levell and A. D. Andrews are the incorporators.

Athens, Ohio—The Canaan Coal Co. has taken bids for the erection of a new one-story boiler plant at its local works, estimated to cost $10,000. The structure will be about 38 x 39 ft., and will be used for increased capacity. Morris Peterman, Rector Building, Columbia, is architect for the company.

Columbus, Ohio—James G. Young, traffic manager of the Columbus Chamber of Commerce, who was secretary of the Franklin County Coal Committee during the war, has been made a member of the Central Territory traffic committee of the U. S. Railroad Administration, with headquarters at Chicago. He will look after coal interests on the committee.

Altoona, Penn.—Two giant steel coal cars of a new design have been completed at the Pennsylvania's steel car plant. The first of the cars weighs 74,000 lb. and has a capacity of 220,000 lb.—110 tons. The second car is known as Class H26, with a weigh. of 82,000 lb. and a capacity of 210,000 lb.—105 tons. Both cars are carried on six-wheeled trucks.

Columbus, Ohio—Announcement was made of the award of Hocking Valley Ry. contracts aggregating about a quarter of a million tons as follows: Essex Coal Co., Columbus, 214,000 tons, at $1.95; Franko Coal Co., Zanesville, 25,000 tons, at $1.95; Cambridge Hocking Coal Co., Columbus, 11,000 tons, at $1.90. In all, there were 21 bids submitted for the business.

Pittsburgh, Penn.—The Pioneer Coal and Coke Co., with headquarters in Pittsburgh, has named Charles F. Colbert, Jr., of Brownsville, Penn., as its general manager. Mr. Colbert for the last eight years had been assistant general manager and sales manager of the Alicia mines of the W. Harry Brown interests. Those mines were recently sold to the Pittsburgh Steel Company.

Columbus, Ohio—Ohio's war record for coal production, recently made public by the department of investigation and statistics of the state industrial commission, shows 48,849,226 tons of coal mined in Ohio in 1918, or 6,000,000 tons more than in any previous year in the history of the state. Belmont County alone produced 12,165,253 tons, or one-fourth of the state's total production.

Okeeffe, W. Va.—The C. L. McPherson Coal Co., recently incorporated under Delaware laws, with a capital of $150,000, is arranging for the development of about 140 acres of coal properties in the vicinity of Okeeffe, to have an initial capacity of about 200 daily, to be increased ultimately to 500 tons. C. L. McPherson, North Fork, W. Va., is president; M. F. Christian is manager.

St. Louis, Mo.—In an opinion recently handed down in the United States Circuit Court of Appeals, a judgment of $600,000 has been set against the United Mine Workers of America to the Coronado County Mining Co., of Sebastian County, Arkansas, for alleged damage caused by members of the union in a strike raid on the property of the company at Jamestown, Ark., and has been conditionally upheld.

New York, N. Y.—The Wilkes-Barre Coal Co., with offices at 123rd St. and East River, makes the interesting announcement that it has taken over a large mine in West Virginia producing one of the best grades of bituminous coal, and that the output is offered to consumers in cargo lots. The company states, also, that it will deliver this coal in any quantity by auto truck to consumers in the metropolitan district. Low prices are quoted for contract or spot delivery. A company expert is available to users who desire specific information regarding burning qualities of the fuel, prices, deliveries, etc.

New York, N. Y.—Work has been started upon a building which it is planned to make the national home for all trade associations now located, or which will locate in the future, in New York City. Among the advantages which are expected from this plan are: Closer coöperation between allied industries; greater convenience for business men desiring to see several associations; special advantages for coöperative meeting rooms, and added prestige due to having a high-grade building devoted to the interests of business men, in the heart of the hotel, railroad and subway terminal districts of New York. The name of the structure will be the National Association Building. It will be ready for occupancy the latter part of next January. Further information may be obtained by addressing Willard C. Brinton, consulting engineer, 17 W. 44th St., New York City.

Chicaga, Ill.—Circuit Judge Harris, acting on the petition of the Latham Coal and Mining Co., has ordered suspension of operation of the mine and appointed Harry G. Adams, of Chicago, as receiver. E. C. Lutz, secretary of the company, reported to the court that the company was solvent, with $25,000 more assets than liabilities, but the company has lost $19,000 in the past year, the officers are liable for $13,000 in obligations and there is $19,000 due for materials and supplies. Mr. Adams, who was formerly with the Jones & Adams Coal Co., has taken charge of all property, assets, credits and collect accounts and is notifying creditors to file statements within 30 days. He will dispose of personal property not needed in the conduct of the mine and will raise money to meet the payroll. The company's bills receivable amount to $15,000. The company states that $65,000 is needed to put the business in a safe and competitive condition.

Weekly Review

Railroads Buying At Satisfactory Prices—Bituminous Industry Awaits General Business Activity—Elimination of Government Control Will Restore Confidence—Anthracite Operators Busy—Domestic Sizes in Excellent Demand

GOVERNMENT attempts at price-stabilization came to an end with the recent resignation of the Industrial Board of the Department of Commerce. The failure of the board to bring the steel producers and the Railroad Administration together had been discounted by the soft-coal industry weeks ago, for it had refused to enter into any negotiations looking to a fixed price for fuel until it received certain assurance that Director General Hines would consider himself bound by any agreement entered into.

It must be stated in all fairness, however, that, contrary to the impression that seems to be prevalent, there is no deadlock in the matter of coal purchases by the railroads. Sales are being made from day to day at prices that seem equally satisfactory to both the railroads and the operators. The price range of coal for railroad use is from $2.55 to roads in New England to less than $2 for roads radiating from Pittsburgh. Between these two extremes is a price of $2.35 for Pittsburgh district coal, while the low figure is for fuel from the Panhandle district of West Virginia.

Judging from the manner in which industry has died off since the signing of the armistice, one would incline to the belief that the major part of American business was the making of war and the manufacture of war materials. The steel industry, for example, a large consumer of coal, at the present time is demanding little fuel, as it is operating only at about 55 per cent. of capacity. Other consuming industries, however, are expanding somewhat, but what the country needs in order to bring about a new era of prosperity is the elimination of all Government control of industry. The return to private ownership of railroads and other public utilities, with the opportunity to operate them at a reasonable profit, will go far toward instilling that confidence without which we must continue to stagnate industrially.

The bituminous coal operators, therefore, are marking time, awaiting in common with others the time when our Government officials arrive at a new understanding. The din and turmoil of battle seem to have so dulled and benumbed the senses of the powers that be that they do not realize conditions have changed. During the war, the Government was the largest customer that industry had, and everything possible was done to bring about a high degree of standardization and centralization. These policies were all right then, but they are all wrong now. The demise of the price-fixing board seems to presage the return of the competitive basis of doing business, and in this direction lies progress—for coal as well as other basic materials.

Shipments of bituminous coal to the lakes have reached important proportions. Operators are rushing coal forward in anticipation of transportation troubles later in the season.

Demand for anthracte is active, and dealers are complaining that coal is not coming fast enough. The stove and egg sizes seem to be the choice of the larger number of consumers, though there is also a good inquiry for broken, chestnut and pea. Due to overproduction, the steam sizes of anthracite are selling at somewhat lower prices than have prevailed for some time, quotations being from 12 to 20 cents per ton lower on the coal produced by the so-called independent companies. The larger operators are storing their surplus of the small sizes. The total quantity of hard coal shipped from the mines in April amounted to 5,224,715 tons, against 3,938,908 tons in March and 3,871,932 tons in February.

WEEKLY COAL PRODUCTION

The production of bituminous coal in the United States during the week ended May 3 is estimated at 8,051,000 net tons and is a considerable improvement over the output of the week preceding. Compared with the same week of last year, however, the current week's production fell 3,324,000 net tons behind. For the calendar year to date, the output of bituminous coal is estimated at 143,773,000 net tons as compared with 189,447,000 net tons during the same period of 1918. The daily average production during the week ended May 3 is estimated at 1,342,000 net tons as compared with 1,356,000 net tons during the period Jan. 1 to date, and 1,787,000 net tons during the corresponding period of last year.

Production of anthracite during the week ended May 3 is placed at 1,695,000 net tons as against 1,401,000 net tons during the week ended Apr. 26 and 1,960,000 net tons during the week of May 2, 1918. For the calendar year to date the production of anthracite is estimated at 25,357,000 net tons and is approximately 25 per cent. below the output during the same period of last year, estimated at 33,134,000 net tons. The daily average per working day during the current week is estimated at 282,000 net tons as against 234,000 during the week preceding, and 239,000 net tons for the calendar year to date.

Shipments of bituminous coal from the tidewater harbors to all points during the week ended May 3 are estimated at 397,684 net tons as compared with 453,074 net tons during the week preceding. Decreases occurred during the week at all harbors with the exception of Baltimore, at which harbor the increase was slight. Loading at Hampton Roads fell behind the most—approximately 37,000 net tons, or 30 per cent.

The tidewater shipments to New England during the week ended May 3 are estimated at 84,066 net tons as against 102,789 net tons for the week ended Apr. 26. The decrease is entirely attributed to the falling off in tonnage loaded at Hampton Roads, the current week's loading amounting to but 28,122 net tons as against 56,455 net tons during the week preceding. During the same week of 1918 total tidewater shipments to New England amounted to 331,470 net tons.

Production of beehive coke in the United States during the week ended May 3 is estimated at 296,163 net tons, and is an increase of approximately 34,000 net tons or 13 per cent. over the production for the week preceding. However, production during the week ended May 3 is but 50 per cent. of the output of the corresponding week of last year. During the current week improvement occurred in production in Pennsylvania, West Virginia, Washington and Utah, while in all other states the output fell even below the output during the week ended Apr. 26. For the calendar year to date the production of beehive coke in the United States is estimated at 7,498,379 net tons as compared with 10,086,351 net tons for the same period in 1918. The daily average for the coal year to date is estimated at 70,738 net tons, while for a similar period last year it was recorded at 95,154 net tons.

Bituminous coal dumped at lower lake ports during the week ended Apr. 26 is estimated at 397,474 net tons and is slightly in excess of the tonnage dumped during the same week of last year, estimated at 370,204 net tons. For the season to date bituminous coal dumpings amount to 958,499 net tons, and is nearly 50 per cent. in excess of the tonnage dumped during the same period in last year.

BUSINESS OPINIONS

Dry Goods Economist—It is evident that business is in a stable condition. From all centers orders for goods are being received and with these orders are many statements showing that consumers are buying liberally and also that they appear well supplied with funds. The course of prices of many commodities is slightly downward, while some other goods have advanced. Where advances occurred they have, as a rule, been due to the payment of higher wages to operatives.

Marshall Field & Co.—Current wholesale distribution of dry goods is slightly less than for the corresponding week a year ago, when there were especially large shipments. More merchants are visiting the market frequently and all report excellent retail business. Orders from road salesmen are in excess of the corresponding week last year for both immediate and future delivery, particularly for fall. Collections are satisfactory.

American Wool and Cotton Reporter—The Boston wool market remains strong and active but buying in the West, or at least the Middle West, has practically ceased for the present on account of the high prices asked by the growers. In the foreign markets the prices are strong. A slightly increased demand from the mills

for cotton continues, but many in the trade do not look for particularly good business until the present feeling of unrest has disappeared. The two prominent factors in the cotton market are peace prospects and the weather.

The Iron Age—Pig iron statistics for April show that that industry is rapidly adjusting itself to the shrinkage in iron consumption. No less than 54 furnaces blew out last month, leaving 212 active as May came in, against 372 on Sept. 1 last year when the peak was reached. In April the output was 2,478,218 gross tons, or 82,607 tons a day, against 3,090,243 tons for the 31 days of March or 99,685 tons a day. Capacity active May 1 was 75,860 tons a day for 212 furnaces, against 93,165 tons a day for the 266 furnaces in blast on April 1. Production at the opening of this month, estimating charcoal iron, was at the rate of 28,000,000 tons a year. This compares with an actual output of 39,052,000 tons in 1918. Not since May, 1915, when there were the first signs of a war demand for American steel, has pig iron production been at so low a rate as today.

Atlantic Seaboard

BOSTON

Market almost featureless. Little inquiry and no change in prices. Bulk of railroad fuel not yet purchased, although one of roads has announced successful bids. Quality grades still firm. Some operators get conservative as to season commitments. Inferior grades slow. Smokeless coals unchanged. Anthracite shipments not sufficient to meet demand on retailers. Slow movement coastwise. Demand continues strong.

Bituminous—The general situation continues without material change. Competitive bidding for railroad fuel tonnage seems to have had very little effect upon current quotations, and the market is as featureless as at any time since January. The differential in favor of all-rail coals is still holding Pocahontas and New River down to a minimum tonnage, confined for the most part to territory immediately accessible to tidewater. There is quiet buying of the better grades from central Pennsylvania, and steam-users long accustomed to the smokeless grades from West Virginia are testing Cambrias and Somersets in the effort to find what they would consider to be satisfactory substitutes. For this reason there is a somewhat better demand for the coals classed as "No. 1," and whatever firmness there is in the present market can be directly attributed to this kind of inquiry.

Stocks are still large and buyers are proceeding very cautiously. It takes constant combing for the different agencies to disclose any contract buying, and spot business is even harder to get than a month ago. So frequently have concessions been made for April and May orders, that buyers expect even lower prices for June and July. It can hardly be said, therefore, that the market in New England is to any extent stabilized.

There is only scattered inquiry and for relatively small tonnages. A large number of manufacturers whose stocks are gradually being depleted are taking advantage of the dull coal market by conducting tests of the different brands of fuel oil now being vigorously pressed on this market. A tonnage which has been estimated as large as 750,000 has been already supplanted by fuel oil. The differential in cost is in favor of the latter, but undoubtedly the largest element in making the change is the continued difficulty large employers have had with labor in their boiler rooms. Oil can be used with a minimum boiler force and for this reason alone is bound to make inroads on coal the next few years. Oil distributors have comprehensive plans for storage at strategic points, and some interesting developments can be looked for. Prices of coal have known no material change the past fortnight. The high volatiles are still in very light request and aside from gas-producing grades there is almost no business for coals of that character. The Fairmont district especially is suffering from the very narrow and restricted market that prevails in this territory

Only one of the New England railroads has announced the successful bids for locomotive fuel for the period ending March 31, 1920. The Boston & Albany awarded 635,000 tons in all to several different shippers, the highest price on Pennsylvania coal being $2.55 per net ton f.o.b. mines. One block of 65,000 tons was bought at $2.15 per net ton, although this was on a coal that takes a 25c. higher rate from the mines. The only price above $2.55 was on Pocahontas, 100,000 tons at $2.75, this to be freighted by water from Norfolk and required for special use on a suburban circuit. While bids have been submitted more than once, no results have yet been announced by either the New Haven or the Boston and Maine, both of which roads have negotiations pending.

The fancy grades on the central Pennsylvania are still being firmly held at previous quotations. Buyers continue to discriminate in favor of these quality grades and it is increasingly difficult to find outlet for even the medium coals from the Clearfield region. Inferior grades continue to be offered in ample volume, but with almost no takers. A certain tonnage is being moved over the New York and Philadelphia piers, buyers being attracted by low figures, but even through this channel the demand is noticeably less than a month ago.

On Hampton Roads coals the situation is practically unchanged. There is a wide variation in price between the offerings of different shippers. Coastwise freights, whether by steamer or barge, are on the basis of $2 to Boston, and as the market stands at present the inquiry for these coals inland is very light and is confined to those consumers who insist upon smokeless and coking coals even though they must pay a high differential for their use. Inland distributors are offering contracts at prices that range from $7.60@$7.90 per gross ton on cars Providence or Boston. So far, however, selling efforts on this basis have had little result.

Current quotations on bituminous at wholesale are about as follows:

	Clearfields	Cambrias and Somersets
F.o.b. mines, net tons	$2.15@$2.75	$2.75@$3.25
F.o.b. Philadelphia, gross tons	4.27@ 4.95	5.95@ 5.50
F.o.b. New York, gross tons	4.62@ 5.29	5.29@ 5.85
F.o.b. Alongside Boston (water coal), gross tons	6.10@ 6.85	6.90@ 7.55

Georges Creek is quoted at $3.20 per net f.o.b. mines.

Pocahontas and New River are being quoted at $4.69@5.14 per gross ton f.o.b. Norfolk and Newport News, Va. Alongside Boston the same grades are being offered at a range of from $6.89@7.24, and on cars Boston and Providence at from $7.60@7.90, per gross ton.

Anthracite—Retailers throughout New England are getting increasingly anxious as the season advances. Much publicity has been given to the difficulty of getting forward coal in sufficient volume, and throughout New England the public is insisting that orders be filled promptly. This is particularly true on egg size, which manifestly will not be needed until next season; but the retail dealers in Boston, for instance, are taking all the orders that come and are trusting to deliveries later on to make good their promises. Many buyers felt at the opening of the season that domestic sizes would come forward much as in a normal year, and that the proportion shipped in April would be relatively large. That was not the case, however, and several large distributors in this market got as little as 5 per cent. of their yearly requirements. Present receipts are by no means sufficient to enable retailers to make anything like the deliveries their trade calls for. Some already have all the business they can comfortably take care of for three to four months ahead. The slow movement of anthracite barges is causing some anxiety, but distinctly there is a better feeling over the outlook now that the Reading fleet is being operated exclusively from Philadelphia. A heavy tonnage comes to this market through that channel, and anything that speeds up the loading of these barges will materially increase receipts at this end.

NEW YORK

Anthracite situation strong, with heavy demand for the domestic sizes. Some so-called Independents quoting coal at slight advances. The anthracite steam sizes quoted at slight decreases, owing to overproduction. Movement in bituminous slow and quotations show much variation. Mines have much idle time.

Anthracite—The situation remains practically unchanged. Demand is active, but the supply of coal is not so large as dealers would like to have it. Production is heavy, but producers and sales agents are endeavoring to distribute the coal impartially, and other parts of the country are just as anxious to secure fuel as is this market, hence the complaints from the local dealers that they are not receiving coal as fast as they would like to get it.

Reports from the coal fields indicate prosperity for the workers. Most of the so-called Independent operations are working full time, their owners in the majority of instances having orders booked ahead for domestic sizes to carry them into July. Practically the same is true of the larger companies, but it was said early this week that all of their operations are not working steadily.

Some wholesale dealers look for a let-up in demand during July and August, with a resumption of activity in early September, which will continue well into the winter.

The lack of supplies is reflected in the cars of anthracite dumped at the local tidewater docks during the seven-day period ended May 9, reports showing 6462 cars dumped as compared with 7022 cars the previous week, a decrease of 560 cars.

Stove and egg are in heaviest demand by the local trade, but there is a good call for broken, chestnut and pea. Orders are plentiful and dealers are heavily booked for future delivery. The product of the so-called Independent operators is being quoted in some cases at slight advances over the regular company schedule.

The anthracite steam sizes are easier than the larger coals, due to their heavy production and the approaching warm months. Quotations are from 12 to 20c. off on Independent product, the larger companies storing their surplus.

The retail situation shows much activity. Much complaint is heard of slow deliveries from the docks, many retail yards having scarcely any of the domestic sizes on hand.

It is said that the formation of another large company to take over several of the present retail yards is about completed, and that it will soon be prepared to begin deliveries.

Several of the City Departments have opened bids for fuel supplies, among them the Board of Education, which requires about 125,000 tons of anthracite and bituminous coal to heat the schoolhouses during the year. Quotations for furnishing and delivering the various sizes to the school buildings range from $10.22 to $12.05 per ton for broken; $10.22 to $12.29 for egg; $10.22 to $12.30 for stove; $8.90 to $10.47 for pea; $7.12 to $8.92 for buckwheat No. 1; $5.89 to $7.94 for buckwheat No. 3, and $7.19 to $9.10 for soft coal, according to Boroughs and places of delivery.

Current quotations, white ash, per gross ton, at the mine and f.o.b. tidewater at the lower ports, are as follows:

	Mine	Company Circular
Broken	$6.05	$7.90
Egg	5.95	7.80
Stove	6.20	8.05
Chestnut	6.30	8.15
Pea	4.90	6.65
Buckwheat	3.40	5.15
Rice	2.75	4.50
Barley	2.25	4.00

Bituminous—The local bituminous market shows little activity. Demand is slow, consumers showing no inclination to stock up. Mining is slow, reports received here being to the effect that many of the openings are idle several days a week, some because of the lack of orders and others because of the attitude of the workers, who, after a couple of days of idleness, refuse to report for work the balance of the week. This may prove to be the salvation of the industry, however, in view of the heavy tonnages thrown back on the market because of the substitution of oil for coal.

It was reported here early this week that one big concern which at one time had an estimated consumption of 500,000 tons of coal annually has now discontinued the use of coal entirely and hereafter would use oil. Similar reports are frequently heard concerning other concerns, but using smaller tonnages of coal.

The danger of a runaway market and higher prices next fall does not cause many of the large consumers to enter the buyer's market for large blocks of coal. They seem willing to take their chances in the open market in securing coal at lower prices and many of them have so far neglected to close contracts for their future supply.

The all-rail trade is in good shape and shows more activity than the tidewater. There is a heavy demand and considerable coal is being put away for future use.

Operators are being approached daily with offers of low prices for coal, but they

are in the main holding strong for prices which will cover the cost of production.

Contract coals are moving steadily, but the spot market is quiet. There is a fair tonnage handled over the local docks, but the dumpings for the week ended May 9 show a decrease from the previous week's dumpings, 5133 cars having been handled as compared with 5955 cars the previous week.

Quotations show a wide variety of prices, much depending upon the urgency of the situation. While the accompanying tabulation shows no change from last week, quotations of various shippers on certain grades for immediate shipment were in some cases slightly lower.

The quotations for the various coals at the mines, net tons, for spot delivery and contract, follow:

	Spot	Contract
South Forks	$2.90 to $3.25	$2.95 to $3.50
Cambria County (good grades)	2.75 to 2.95	2.95 to 3.25
Clearfield County (good grades)	2.50 to 2.75	2.80 to 2.95
Reynoldsville	2.50 to 2.75	2.75 to 2.95
Quemahoming	2.65 to 2.85	2.95 to 3.10
Somerset County (best grades)	2.65 to 2.85	2.95 to 3.10
Somerset County (poorer grades)	2.00 to 2.35	2.50 to 2.75
Western Maryland	2.25 to 2.75	2.50 to 2.75
Fairmont	2.00 to 2.25	2.35 to 2.50
Latrobe	2.10 to 2.25	2.25 to 2.40
Greensburg	2.25 to 2.35	2.35 to 2.60
Westmoreland ¾ in.	2.60 to 2.75	2.60 to 2.75
Westmoreland run-of-mine	2.35 to 2.60	2.35 to 2.65

PHILADELPHIA

Anthracite demand continues extra strong. Dealers grow impatient at slow deliveries. New business not being sought. Production below normal. Enough stove business for entire summer. Nut not far behind. Pea shows some signs of strength. School coal awarded. Steam sizes in fair call, but smallest sizes go to storage. Bituminous drags along. Good coals in fair demand. Little spot grade. Some improvement in contracting.

Anthracite—There is a growing tenseness of feeling at this time between the retailers and the operators. This is due on the part of the former to their strenuous efforts to obtain shipments to meet the number of orders which have been placed on their books. As a result many of the dealers are becoming unreasonable, as they are insisting upon coal all at the same time. For the moment they have apparently lost sight of the fact that the mines do not produce enough coal in April and May to allow them to fill all their orders and also stock their yards, as some dealers are trying to do. A few years ago we saw coal arrive in the city on the morning of Apr. 1 at that month's price. This was when the stocks in the storage yards were drawn upon during the last few days in March and the coal loaded and started to market on the last day. The retailers are losing sight of the changed conditions and are making miserable the lives of the selling agents.

It is, of course, no use to remind the dealers that the markets of the country lost almost 4,000,000 tons in February and March, after the spring prices were announced, simply because the retailers were afraid to stock coal at that time. Nevertheless this is a fact, and the buyers of coal are feeling the result of it now, for it is tonnage lost that cannot be made up. When the buying actually started a great amount of business was taken from the retail men with the distinct understanding that shipments would be slow, and now some of them are calling daily and demanding immediate consignments.

The result of the rush during the past few weeks has been that the operators are refusing all new business for egg, stove and nut and most salesmen have been instructed by their houses to solicit no new orders for these sizes. For the present at least there appears no hope of increasing the production at the collieries, and due to various celebrations in the region on account of returning soldiers, the tonnage to date this month has been away below normal.

Stove is by all odds in greatest demand, and if all the orders recorded are bona fide the output for all summer has been sold. Chestnut, too, is very active, but a greater amount of it continues to arrive here. Some shippers appear to be longer on egg than others, but as a whole the market is short of it, as the demand is unusual. Pea has strengthened and all the best grades are in fair demand here. There may be concessions in price by some of the smaller operators, but there is no sharp price cutting. As a matter of fact we have heard of some shippers compelling customers to take a certain quantity of pea in order to receive stove and nut. The fact that one of the heaviest buyers of this size and who was the first to announce a substantial reduction in the retail price when the break came earlier in the spring, has recently advanced his rate 75c. a ton, shows the market has improved. Others have advanced from 25c. to 50c. Yet in the face of this improvement one of the largest companies is still unable to move its entire production to market and continues to place some tonnage in the storage yards. Speaking of pea, it is also worth mentioning that the bids for fuel for the various school houses of the city, including 25,000 tons of pea, were practically all based on circular prices. Where concessions were made the differences were slight. The dealers' bids for hauling were, however, much lower than anticipated, the competition being surprisingly keen. Whereas much of the hauling was done around $2 last year bids as low as $1.40 were received this season.

The big producing companies are quite optimistic as to the future for the large sizes. Their officers say the demand is sure to carry them through June and perhaps well into July. Undoubtedly the dealers will want to go into the fall with full stocks, so will continue to buy after all their orders on hand have been filled. We know quite a few dealers who intend to stock heavily on nut coal in place of pea, and will not altogether neglect this latter size either, but will store a much reduced tonnage of it.

It is believed that there will be many days this summer when the dealers will be out of certain sizes, for the demand from other territories for fuel is also very strong. The demand for family sizes is great from all districts, and while operators have made substantial shipments they are hopelessly short of the demand.

There is a fair demand for steam coals, but buckwheat is the only size that is really active. As it now stands, the production of this size is just about absorbed and no more. Rice, which has of late shown signs of improvement, has failed to hold it this week. At this writing there is actually more of this coal than the trade is able to take, and as a consequence a good tonnage is once more being sent into storage. Naturally barley has also failed to improve, and the piles of this size in the storage yards grow and are causing much anxiety to the companies.

The loss of broken coal tonnage has been general, as many of the gas companies have gone on coke. Some producers profess that this does not embarrass them, as they would rather break this size down and get better prices as family coal. It appears that the concerns most affected are those having a coal of a fragile nature which when broken down creates a heavy percentage of the extremely smaller sizes.

The prices per gross ton for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$5.95	$7.80	Buckwheat	$3.40	$4.45
Egg	5.95	7.80	Rice	2.75	3.65
Stove	6.20	8.05	Boiler	2.50	3.50
Nut	6.30	8.15	Barley	2.25	3.15
Pea	4.90	6.50			

Bituminous—The condition of soft coal is indifferent. There are some shippers who actually claim they are sold up, while others are making but very short time. Of course, as has been the case right along, the good coals find no difficulty whatever in making a market. A large proportion of this production continues to go into the New England market on contract orders.

Some shippers also report a more satisfactory condition as to contract inquiries recently, a number of fair-sized consumers having closed for their tonnages this past week. All concerns are still receiving many inquiries and more than a usual number have seemed to actually want coal lately.

There have practically been no price changes during the past week and they rule about as follows:

Georges Creek Big Vein	$2.90 @ $3.00
South Fork Miller Vein	2.90 @ 3.00
Clearfield (ordinary)	2.75 @ 2.90
Somerset (ordinary)	2.55 @ 2.70
Fairmont lump (ordinary)	2.40 @ 2.50
Fairmont mine-run	2.15 @ 2.25
Fairmont slack	1.90 @ 2.00

BALTIMORE

Soft-coal market uneventful, Fair prices maintained on best grades with cutting on other coals. Contract-making almost dead despite possibility of coal shortage. Hard coal men fairly busy.

Bituminous—There is no snap to the market here. What trading there is, is generally on a basis of fairly good prices for the best coal, with some sharp cutting at times on the less desirable grades. The nature of these sales, at prices considerably off the lowest rates offered on contract, is such that there is no general inducement for consumers to get under cover. For that reason the purchasing in the open market is about the only sign of activity.

Coal men are beginning to point out to their clientelé that the production of soft coal at this time is so far below consumption, and the distribution of mine labor has been so wide to other industries, that when the end of summer comes there may arise a situation where it will be difficult to make contracts to assure a fuel supply.

A feature of the market here is that the jobbers are planning for a vigorous business this fall. All the old clouds of Government regulation for jobbers, even to the point of their suppression, have gone, and the mines and consumers are both turning more than ever to the middlemen to help out. Several new names are noted in the coal-brokerage business, and none are apparently disappearing. The export movement was not so heavy last week. The total loadings on foreign coal cargo carriers was but 9349 tons, largely due to light reporting of bottoms at the piers.

Anthracite—The anthracite market continues fairly active. Dealers report that they are still delivering on orders received in April as the receipts from the mines did not enable them to put out in their hauls the tonnage they could otherwise have delivered. Some large anthracite contracts are now being made, as there is no advantage in holding off as in the cheaper spot market for soft coal. The city has awarded a contract for 15,230 tons for some municipal departments, to the Chesapeake Coal Co. for a total of $158,552.

Lake Markets

PITTSBURGH

Railroads buying coal steadily. Railroad coal price stabilization plan dead. Lake shipments of gas coal heavy. Market prices unchanged.

The idea still seems to survive in some quarters that there is a deadlock, or a near deadlock, in the matter of coal purchases by the railroads. The fact is that purchases are being made from day to day, at prices that seem equally satisfactory to the railroads and to the operators who make the bids. The coal price stabilization plan of the Industrial Board was tabled long ago, until it could be seen whether the Industrial Board could bring the Railroad Administration to an indorsement of the steel prices the steel producers had quoted, and with last week's positive and final failure of the steel producers and the Railroad Administration to get together, the coal plan died a natural death. Leading Pittsburgh coal operators had already practically forgotten it.

The railroads radiating from Pittsburgh are buying Pittsburgh district coal at various prices, according to quality, the highest price being the regular $2.35, which as reported last week was done on a contract for 1200 tons a day to Apr. 1, 1920, between the Pennsylvania Lines East and the Pittsburgh Coal Co. For shorter periods the railroads would be unwilling to pay as much, thus agreeing with the belief expressed by operators that coal prices will be higher next fall and winter than this spring and summer. The lowest prices paid have been for Panhandle coal, which in some cases is understood to have gone to railroads at less than $2.

The steel industry is consuming less and less coal each week. Its average operation was 65 per cent. of capacity in April, against 77 per cent. in March, and the rate this week is hardly above 55 per cent. Some other consuming industries, however, are expanding their operations somewhat.

Lake coal shipments have now reached important proportions, and in the case of high-grade gas coal there is almost a rush to get coal forward, in anticipation of possible transportation difficulties late in the season.

Production in the Pittsburgh district continues at about 50 per cent. capacity. The market remains quotable as follows:

Byproduct coal, largely nominal, mine-run, $2.35; high-grade gas coal, slack, $2.10@2.20; mine-run, $2.35; ¾-in., $2.50@2.60; 1¼-in., $2.60@2.70; steam, slack, $1.90@2; mine-run, $2@2.35; all per net ton at mine, Pittsburgh district.

TORONTO

Rush of orders for hard coal continues. Dealers behind in deliveries. Shipments from mines light. Bituminous quiet. Industrial conditions unsettled.

There is a continued heavy demand for anthracite, consumers being anxious to lay in stocks before prices are raised. Shipments from the mines are light and supplies in the yards depleted. Dealers are considerably behind with deliveries, and new orders are only accepted subject to the price prevailing at the time of delivery. Bituminous is not much in requistion and dealers have ample stocks on hand. The industrial situation is considerably unsettled owing to extensive strikes in the metal and other trades, which have a tendency to further restrict the demand.

Quotations for short tons are as follows:

Retail:	
Anthracite, egg, stove, nut and grate	$11.50
Pea	10.00
Bituminous steam	8.25
Slack	7.25
Domestic lump	10.00
Cannel	11.50
Wholesale f.o.b. cars at destination:	
Three-quarter lump	6.00
Slack	4.75 to 5.00

BUFFALO

Small change in coal situation. Bituminous prices being cut. Anthracite in great demand. Lake shipments keep up fairly well in spite of complaints of scarcity.

Bituminous—Jobbers confess that trade does not improve, but continue their predictions of good business before long. Some of the districts, especially Ohio, are cutting slack prices. Some low figures are reported. Allegheny Valley, which was expected to be the first to reduce prices, claims that it is holding firmer than any other district. There was a shadow of car shortage, especially in grain and flour carriers, a short time ago, but that has about disappeared. Buffalo is loading 300 to 500 cars of grain a day for export. They can come back with coal, if needed, and thus relieve the open coal cars.

Bituminous prices are fairly strong, except slack, as follows: Thin-vein Allegheny Valley all grades but slack, $4.65; Pittsburgh and No. 8 lump, $4.45; same, mine run, $4.20; all slack $3.80, per net ton, f.o.b. Buffalo.

Anthracite—The heavy demand on the part of householders continues. Some days the distributors find it almost as heavy as it was during the big shortage. Egg has been especially scarce. An effort is made to keep up the lake shipments, though the local and rail demand would take it all if allowed to do so.

It looks as if the cellars will be well provided with supplies when the fall trade sets in. At the same time operators and shippers find it hard to keep up the supply.

The amount of anthracite loaded for the lakes for the week was 105,400 net tons, of which 23,700 tons cleared for Fort William, 19,500 tons for Milwaukee, 15,400 tons for Duluth and Superior, 14,100 tons for Chicago, 8500 tons for Hubbell, 7935 tons for Green Bay, 7000 tons for Waukegan, 3500 tons for Houghton, 2100 tons for Port Huron, 825 tons for the Sault.

Freight rates have been readjusted at 90c. to Port Huron, Sault, 52½-60c. to Chicago, 47½c. to Waukegan, Milwaukee, 42½c. to Duluth, Fort William, Hubbell, Portage, Marquette, Green Bay.

CLEVELAND

Virtually the only semblance of life in the local bituminous coal market is given by the lake trade. Steam-coal users are meeting spot needs only. The April movement of coal to Lake Erie ports was 30 per cent. ahead of April, 1918, but the May report may not be so favorable.

Bituminous—Coal operators here more and more are reaching the conviction that business is not being held up by the Peek-Hines controversy over steel-rail prices, but is awaiting the definite news that the Government has taken its hand off all business. The threat that Washington may at any time exercise the control within its power is said to be the underlying cause of the present dullness. Capital, naturally timid, will not bestir itself so long as the war powers of the President continue, is the statement. Whether the iron and steel industry, the largest single consumer of coal in northern Ohio, will gain anything like normal activity this summer, not to consider the fact that 1920 is a presidential year and history may be expected to repeat itself in presidential year dullness, is receiving serious consideration. The number of operators fearing subnormal conditions in the coal market for a period of at least months is growing fast. Operators are well agreed, however, that excessive production costs will serve to keep prices up regardless of slack demand.

With the lake trade taking mostly prepared sizes and very little slack, the piles of slack at eastern and southern Ohio mines become larger daily. Large buyers who have declared they would take slack again about the middle of May have made no move so far to make good their promise. Slack from $1.45 up is plentiful. Railroad fuel is moving at $2.10 and $2.15. Mine-run, which held at $2.35 during the war, now ranges as low as $1.90. The price of No. 8 ¾-in. lump for lake shipment continues to hold at $2.30 to $2.40.

Domestic consumers are showing a remarkable appetite for Pocahontas and anthracite, considering the holdover tonnage from last winter. The spur of advancing prices and the advertising campaign being carried on by the Pittsburgh Vein Operators' Association of Ohio has had a good effect upon the domestic trade, if not upon steam-coal buyers.

Lake Trade.—To May 1 Lake Erie car dumpers loaded 1,067,501 tons of bituminous coal for shipment to the upper lakes. Fuel coal handled in April amounted to 52,717 tons, making the grand total 1,120,218 tons. To May 1, 1918, the docks handled 860,797 tons of cargo coal and 30,249 tons of fuel coal, making the 1918 April total 891,046 tons. Duluth and Superior are said to have received 308,200 tons of bituminous and 78,500 tons of anthracite to May 1. Lake Erie docks are handling from 1700 to 1800 cars of bituminous a day now. Some carriers are coming down light for coal, so scarce are iron-ore cargoes. Many cargoes of coal loaded at Lake Erie ports are being held there pending an improved iron-ore market.

The following are coal prices in Cleveland, net ton delivered:

Anthracite:	
Egg	$10.85 to 10.95
Chestnut	11.15 to 11.25
Grate	10.95
Stove	11.05 to 11.15
Pocahontas:	
Forked	8.50 to 8.75
Lump	7.75 to 8.00
Mine-run	7.20
Domestic bituminous:	
West Virginia splint	7.05 to 7.15
No. 8 Pittsburgh	6.10 to 6.35
Massillon lump	7.15 to 7.25
Steam coal:	
No. 6 slack	4.30 to 4.40
No. 8 slack	4.70 to 4.85
Youghiogheny	4.90 to 5.10
No. 8 ¾-in. lump	5.35 to 5.50
No. 6 mine-run	4.40 to 4.50
No. 8 mine-run	4.70 to 4.85

DETROIT

Inactive demand and scattering sales of small size are features of the bituminous trade in the Detroit market.

Bituminous—Procrastination is seemingly the favored policy among Detroit buyers of steam or domestic coal of the bituminous type. Jobbers and wholesalers report business is unsatisfactory. The orders received are of small size and are coming in irregularly, in many instances suggesting that buyers are endeavoring to fill in temporarily, that they may be able to defer placing a larger business until a later period.

Unusually large stocks remaining in storage yards of the larger industrial plants and held by many of the retailers are said to be primarily the cause of the general indifference to bituminous coal, though among some of the buyers the unsettled general business outlook and a theory that prices may be lowered are also factors tending to delay placing orders.

Considerable of a reduction from Fuel Administration prices is apparent in quotations reported by some of the dealers as effective at the mines on short ton shipments. Splint or gas lump from West Virginia is quoted at $2.56 a ton, three-quarter lump $2.50, mine run $2.25, and slack $2, though prices are described as approximate. On Hocking lump the price is about $2.50, on mine run $2, and on slack about $1.50. Coal of good quality from other Ohio sections is said to carry about the same price. Smokeless lump and egg is scarce, and dealers are getting just about any price they place on it, while mine run of the same description brings about $2.75.

Anthracite—Domestic buyers are not coming into the market for anthracite as rapidly as dealers would desire, although warnings have been given repeatedly that prices will be higher to those who put off buying until later in the year. Most of the larger retail yards seem to have a comfortable supply of the prepared sizes, though receipts have not been of large proportions.

Lake Trade—Vessel managers are experiencing difficulty in obtaining cargoes for loading vessels for the downbound trip from the head of the lakes, with the result that a few carriers have been sent down without cargo to load coal. This, however, is regarded as unprofitable by the vessel-men. The cargo scarcity is having the effect also of delaying the start of numerous vessels which usually share in the coal trade and is the cause also of quite a number of vessels that have loaded coal being held in Lake Erie ports to await a brighter freight outlook.

COLUMBUS

There is a better feeling in the steam trade in Ohio territory. Inquiries are more numerous and some few contracts have been closed. Railroad contracts have also been announced. The domestic trade remains quiet, except for fancy grades.

The steam trade is now attracting the bulk of the attention of producers and shippers alike. While the price question is still unsettled, still there are some signs of an agreement between purchasers and sellers. Inquiries are more numerous, indicating that reserve stocks are being depleted and that purchasing agents will be in the market. Some of the larger users still have large surpluses, but in many cases it is of inferior coal and they are trying to buy some better fuel in order to mix with the poorer grades.

The demand for the small sizes is still slight, which is causing an oversupply of screenings. With the opening of the lake season that situation was not improved and, if anything, was made worse. Low prices are being asked for screenings and in some cases it has become a drag on the market. But taking it all in all, the steam trade is in slightly better shape than was the case several weeks ago and producers look for a continued improvement.

Railroad business has been booked around $1.90 and $1.95 for mine-run. A fairly large tonnage was purchased at those figures. This is expected to be a moral force to bring about general contracting as it has set price levels which are expected to maintain for some time. Some of the idle mines in the Hocking Valley and Pomeroy Bend have been opened, and this is proving an incentive to sales managers to hustle for business.

The lake trade is becoming more active, although there is no great movement as yet. Dock owners are shipping a larger part of the tonnage moving. Some lake agreements have been entered into with prices left blank, to be supplied when stabilized prices are arrived at. It is not believed that any great lake movement will develop before June 1.

Production has been slightly better in all of the producing fields of the state. This is especially true of the Hocking Valley and Pomeroy Bend fields, where the output is estimated at 40 per cent. of normal. Eastern Ohio is producing about 42 per cent. while Crooksville and Cambridge are credited with about 35 per cent. In mining sections there is a growing scarcity of labor, which is expected to become more acute as the season advances.

CINCINNATI

Market still quiet, though domestic demand is picking up. Stocks of smokeless coals running low. No contract activity.

The coal situation here is still quiet, although domestic demand increased somewhat during the past week. The trade in general, however, remains below normal. Prices were well maintained, and in some quarters the opinion prevails that prices will increase before the end of the summer season. There is a plentiful supply of bituminous coal on hand in this vicinity, but the smokeless grades are running low. In fact, the demand for smokeless coal is

much greater than the supply, and the local dealers are experiencing some little trouble in supplying the demand.

There is not much activity in contracting, dealers as well as consumers still remaining a little cautious. The local dealers are using every available means to get the consumer to buy, but so far have not been able to stir up any great amount of sales. They fear that this will result in a serious shortage when the buying begins, as it will again be a problem of transportation.

LOUISVILLE

Mines reporting fair domestic business, but dull steam demand. Retailers carrying fair stocks, but unable to develop spring stocking orders. Outlook for big fall rush at high prices.

The mines of Kentucky are operating on a fair percentage basis, but are short on orders for mine-run and nut and slack. A large part of the business has been on clean block coal. However, the retailers are rapidly loading up and are beginning to stop shipments, as they are unable to make deliveries and get rid of the surplus.

Railroads have been playing around considerably before placing contracts. The Louisville & Nashville has made most of its contracts for the season, but the Seaboard, Southern and other lines are still to be heard from.

Production in the mine sections is holding up very well, but are expecting duller movement if the retail situation does not change. Prices are firm and showing no change, although some steam coal is being quoted at under regular figures.

Quotations at mines:

	Eastern Kentucky	Western Kentucky
Block	$2.90@$3.25	$2.60
Egg	2.75@ 2.90	.....
Run-of-mine	2.35@ 2.40	2.35
Nut and slack	2.00	2.05

BIRMINGHAM

Buying of steam coal continues light, while movement to railroads has fallen off during past week. Domestic sizes about sold up through the year. Production shows a decline.

There is little inquiry or demand for steam fuel in this market, the accumulation of stocks in the hands of consumers still being sufficient to meet their restricted needs. There has also been a slump in the movment of contract coal, principally among the railroads, which are now taking about the minimum tonnage required in their agreements. Prices remain stable on basis of the Government schedules in effect as of Jan. 31, which are as follows per net ton mines:

	Mine-Run	Prepared	Screenings
Big Seam	$2.45	$2.75	$2.40
Black Creek and Cahaba	3.45	3.75	3.10
Corona, Pratt	2.85	3.05	2.45

Inquiry for domestic sizes has not slackened and there is a scarcity in this grade of fuel to meet present demand. Practically all sizes have been sold up through the remainder of the year and into the first quarter of 1919 in many instances. Prices are as follows per net ton mines:

Carbon Hill	$3.15
Corona	3.40
Big Seam	2.90
Black Creek and Cahaba	3.85@4.50
Montevallo	5.00

Operations at commercial and domestic mines are about on the same schedule as has been in effect for the past several weeks. Only a small percentage of the collieries of furnace companies are running, as iron production is at a very low ebb in this district. The Woodward Iron Co. is preparing to start up one or two stacks to supply some off-grade iron needed on contracts, which will necessitate an increased coal production from their mines.

Coke

CONNELLSVILLE

Prompt furnace coke stiffer still. Bottom about reached unless coal declines materially. Foundry coke demand improved.

The stiffening in the spot furnace coke market has continued. This represents in part the taking off the market of a few thousand tons of coke by a large coke and furnace interest which had labor trouble at its Vesta mine, and in part the closer djustment the coke operators have effected of production to contract requirements. Prompt coke, however, is still available at not above the $4 price commonly recognized in settling for May deliveries under contracts, and usually at somewhat less.

A considerable range of prices obtains on contract deliveries. Two or three contracts remain unadjusted at the old $6 Government price. The remaining contracts that had been written subject to "last Government price" were adjusted some time ago to $5, but it does not seem that further adjustments have been made. Contracts calling for monthly adjustment of price whenever Government control should be removed have been adjusted approximately as follows: February, $5; March, $4.50; April, $4.25; May, $4.

Any further decline in coke prices of any moment would depend on the coal market. If coal is maintained in the neighborhood of $2.35, furnace coke is hardly likely to go much below $4, as that price does not allow any profit for converting coal into coke.

There has been a distinct improvement in the demand for foundry coke, and particularly of the better grades. Very good grades are obtainable at $5, and it is held that it pays foundries to use such coke rather than the cokes that can be picked up at $4 and $4.25. The market is quotable as follows: Spot and prompt furnace, $3.75@4; spot and prompt foundry, $4.25@5, per net ton at ovens.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended May 3 at 133,606 tons, a decrease of 1756 tons.

Buffalo—The trade is still quiet, waiting for the iron movement to grow. It is believed that the time is not far off, but till it arrives it will not be easy to sell coke. Quotations, f.o.b. Buffalo, are $7 to $7.25 for 72-hour foundry, $6.60 for 48-hour furnace and $6.10 for off grades.

Middle Western

MILWAUKEE

The coal market continues quiet. Dealers urge consumers to buy and predict higher prices later on.

The coal market continues quiet, with only a fair demand. The announcement of the new scale of prices on May 1 elecited little comment, and it is evident that consumers fully realize that they are in for a continued period of high-priced fuel. The coal dealers have started a campaign of newspaper publicity in an endeavor to induce their customers to put in their supplies for next winter as early as possible, the prediction being advanced that prices will be higher later on. Coal cargoes are reaching port at the rate of three or four per day, the receipts from this source since the opening of navigation aggregating 113,303 tons of anthracite and 245,485 tons of bituminous. The Central Coal Co., which has not handled lake coal for several years, confining its business to Illinois rail coal, has received one cargo thus far over its dock. This company handles the fuel supply of the Chicago, Milwaukee & St. Paul Railway Co.

ST. LOUIS

An unusually quiet market with an impatiently waiting trade ready for the storage season, which it is hoped will soon open. No country demand for anything but a little anthracite, and the city steam and domestic is at a standstill.

The quietness that prevailed a few weeks ago is nothing compared to the unusual quietness that is prevalent now in the local trade. The only coal that is moving at all of domestic sizes is a little anthracite, which is going to a few dealers in the country. This is about the only thing that the country trade is calling for.

There seems to be an absolute shutdown of industrial plants outside of St. Louis, judging from the small amount of steam tonnage that is moving. The country trade never stores coal early and the result is that such coal as is moving is confined to St. Louis and one or two of the larger cities adjacent.

The steam business in St. Louis proper is at low ebb. There is so little demand that every time a buyer is in the market for a car or two of coal there are anywhere from 10 to 40 who are willing to cut the price a little under the previous price in order to get the business. The prices that were maintained a few weeks ago, which were to cover the cost of production in the Standard field, are utterly disregarded at the present time by the majority of operators. Coal is selling for far below cost of production, and how long this will continue is problematical.

The mines in the Standard field are working anywhere from one to three days a week. In the Mt. Olive field conditions are somewhat better and prices are pretty well maintained. In the Carterville field of Williamson and Franklin Counties, as well as in the Du Quoin field of Perry County, there has been some improvement the past week in the call for domestic sizes, this being mostly from points in the far north, evidently for storage purposes.

Steam sizes are in exceptionally good demand, all of the smaller sizes of nut and screenings bringing practically the top price for the better grades of coal.

The present prevailing prices per net ton f.o.b. mines are:

	Williamson and Franklin County Association:	Mt. Olive and Staunton	Standard
Lump, egg and nut.	$2.75	.....	.....
Washed Nos. 1 and 2 nut	2.85	.....	.....
Independent:			
Lump, egg and nut	2.55	$2.55	$2.00@2.25
Washed Nos. 1 and 2 nut	2.85	.....	.....
Mine-run	2.35	2.20	1.60@1.75
Screenings	2.20	2.05	1.15@1.30
3-in. lump		2.30	.....
2-in. lump		.....	1.75@1.90
2x6 egg		.....	1.85@2.00

Williamson-Franklin County rate to St. Louis is $1.07½; other rates $0.92½.

COAL AGE

Volume 15 New York, May 22, 1919 Number 21

The Coal Business of Tomorrow

By Floyd W. Parsons

WHAT is the nature of the situation we are approaching? That is the question common in the minds of all coal-mining people. Like most of our important basic industries, the coal business is caught in the cycle of a great change. Not only is this true in the social side of the industry, but it is also a fact in the physical end of the mining business.

In many famous coal regions, such as Cambria and Clearfield Counties in Pennsylvania, the original areas are practically worked out. Operating companies are now going over their acreage, taking out pillars and working low-grade thin seams. Some beds are being worked that wouldn't have been looked at five years ago. All of this means high operating costs and a lower grade of product.

Ten years ago the Freeport seam near Pittsburgh, in Allegheny County, sold for $50 per acre; recently this same coal sold for as high as $700 per acre in blocks. In southern West Virginia, no longer than a decade ago, coal leases were made on a royalty basis of 6 to 10 cents per ton; now they range from 25 to 30 cents per ton. Many great industrial companies, especially large steel corporations, are experiencing difficulty in getting a supply of the proper grades of coal. Some of them have already decided that the only solution for their fuel problem is to secure acreages of inferior coal and carefully prepare it at the mine.

We know now that the mining waste of the old days was appalling and unnecessary. But nevertheless it was in keeping with those prodigal times. The railroads are largely responsible for the conditions that existed. Coal fields were opened chiefly to get freight tonnage for the roads. These carriers also fixed the price and dictated the point where the coal should be sold, so as to reap the benefit of a long haul and a high freight rate. Is it any wonder that mining was an unprofitable industry when in reality it was a sort of subsidiary business carried on to fatten the treasuries of great transportation systems?

But that time is no more. High-grade coals are growing scarcer daily. No new fields are being discovered, and none will be. The people understand at last the value of our coal heritage. The Government, acting as the representative of the people, will see that no further reckless wastes are permitted. Higher prices, urgent industrial needs and the competition of fuel oil will necessitate the application of science to every phase of mining. The entrance of America's largest financial interests into the coal business further insures a new and greater degree of stability in the industry.

The coming decade will see greater advances in coal mining than ever before, but the progress will not be along the same lines. The tomorrow of the colliery owner will be replete with developments having to do entirely with the art of utilizing fuel, and not so much to do with the art of producing it. The problem will be to redeem all the values locked up in the coal rather than to simply mine and wastefully burn the native article. Instead of shipping all our output in bulk by rail, we will save millions of dollars worth of valuable coal products and transmit the remaining energy of the fuel by wire to the point where the power is needed. Private interests must at last give way to national economy.

If coal operators continue to be indifferent to the methods of coal consumption, the immediate future lies dark ahead. Oil from Mexico has replaced one million tons of coal in New England since the war ended. This same competitor threatens the whole coal business of the Atlantic seaboard. The Mexican oil fields are one of the prizes of the world. It is only necessary to turn a few valves to increase the output of Mexican oil 400 per cent. Gas is the perfect fuel, but it cannot be transported long distances. Oil, therefore, at present is our supreme fuel. This would not be the case if no heat were lost in burning coal. The time has come when colliery owners must lock arms with science if they intend to march to victory.

IDEAS AND SUGGESTIONS

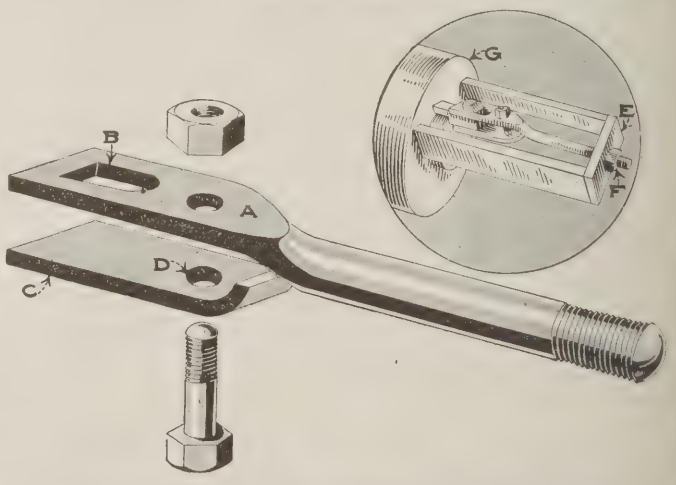
Robbing Pillars in Anthracite Mines

By Joseph R. Thomas
Assistant Mine Foreman, Plymouth, Penn.

Robbing pillars in the anthracite mines sometimes presents many difficult problems to the mine foreman and the men actually engaged in the work. An important and most difficult thing is to safeguard the lives of the workmen from falls of roof and rib. In order to eliminate these accidents as far as practicable, it requires a careful daily inspection of all working places while the men are at work. The person making the inspection gives instructions to the miners in regard to setting the necessary props and other timbers. But as the work of drawing pillars progresses it is sometimes found rather difficult to keep the workings supplied with pure fresh air. When pillars are taken out the sectional area of the opening is increased many times what it was previous to the work of robbing. Therefore, the velocity of the air is reduced so low that the smoke caused by the blasting hangs for some time before it is carried away. Furthermore, where robbing is carried on in more than one lift that is ventilated by the same split it is found increasingly difficult to maintain sufficient ventilation.

The cost of timbering in drawing pillars is so high in some seams in the anthracite region as to make robbing almost profitless to the operator. It is in these bad seams that the mine foreman is confronted with many perplexing conditions, in order to produce the coal at the lowest price per car possible. In order to do so he must be constantly on the lookout for miners who do unnecessary propping and timbering in order to make high wages. And permit me to say that it is right here that the foreman has to use his best judgment in regard to safety and cost; the foreman should be thoroughly acquainted with the nature of the roof that is to be supported, for sometimes he has to censure the miners for doing unnecessary timbering. Then the miners will come back at him and say: "The roof is bad." "Me 'fraid to work that place, me no stand lotse props." What is left for the foreman to do but to use his best judgment and try to explain to the miners the best possible way to protect their lives and at the same time reduce the number of props used daily.

It is evident that one prop or set of timbers that is properly placed may be equivalent to half a dozen that are set in a hurried and improper manner. Where props are use extensively it is sometimes found advisable, in case the roof is of a broken-up nature, to use extra long cap pieces on the props. For while the cap piece itself does not hold the roof, it offers a good warning to the miner that the weight is getting heavy on the props. And it is my opinion that where it is not necessary to support the roof in order to protect the surface plant, much of the timber employed could be recovered and used the second or third time. By adopting some means of drawing the timber and allowing the roof to fall, the weight would be decreased on the pillars and the work of robbing would be much safer for the miner and cheaper for the company. The increasing cost of timber will in time necessitate the greater use of steel and cement props for supporting roof at other points in mines than shaft bottoms and partings.



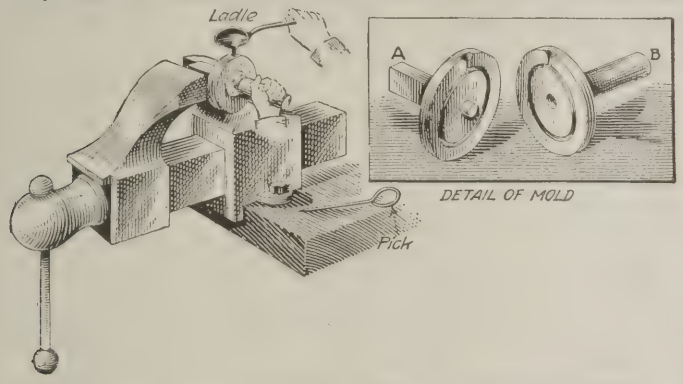
In flat or moderately inclined seams the pillars can be extracted much more easily than in seams pitching from 20 to 30 deg., other conditions being favorable. As the work of drawing pillars involves considerable expense for timber, I would like to hear what others have to say on this subject in the columns of *Coal Age*, and I would also like to know whether there is any machine or apparatus for drawing timber from worked out areas. I hope to receive the advice of others who have had considerable experience in this line of work.

[The "Sylat" post puller, made by W. Sylvester, of Parkersburg, W. Va., is used not only to pull props but also to afterward drag them away without danger to the workman.—Editor.]

Practical Key Extractor

By Charles H. Willey
Concord, N. H.

The key extractor here shown is made with a bolt of suitable size and strength for the key that is to be extracted. The illustrations give both detail and working views. To make the device calls for no great amount of skill. The bolt is heated and flattened to half thickness, and the flattened section (*A* Fig. 1) is offset a little. A hole to fit the key head is drilled and filed at



DETAIL AND WORKING VIEWS OF AN EFFICIENT KEY EXTRACTOR

B and a small strap made of flat steel, as at *C*, is also made, and holes drilled for bolting these two parts together, as at *D*. In operation the slotted part is placed over the key head with the strap on the under side, and then the two are bolted together. Suitable distance pieces and the strong back *E* are put in place, and while tightening up the nut *F*, hammer blows are struck on the hub at *G*. The key will respond to this device almost every time.

Homemade Lead Gasket Outfit

By J. L. Ball
Amsterdam, Ohio

At all mine plants where water-tube boilers are used, some arrangement should be made to have a gasket-making outfit to furnish lead gaskets for the handhole plates. Notwithstanding that some composition gaskets give good service while in use, it is impracticable to employ them more than once. Furthermore, should the feed water be of such a nature as to necessitate frequent washing out, or turbining, of the tubes, these purchased gaskets constitute quite an item of expense. On the other hand, lead gaskets give excellent satisfaction; they can be used time and time again by remelting

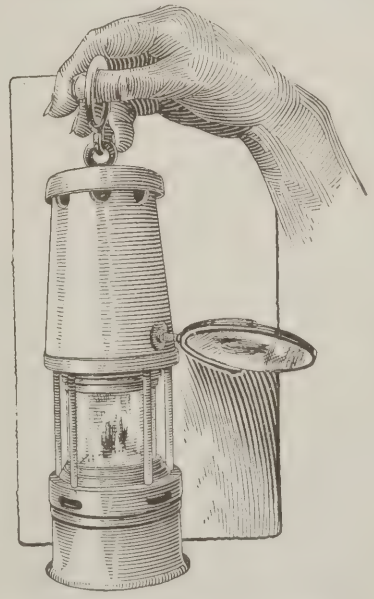
DETAILS OF A HOMEMADE LEAD GASKET OUTFIT

them and remolding; and aside from the initial expense for apparatus and lead, the cost for making them is small. With a little experience a man can mold enough gaskets during his spare time to last quite a while. Though lead deteriorates, still, if care is exercised in saving all scrap and old gaskets, it is not often necessary to use new metal.

The outfit shown has been used for several years and has been copied (with modifications to suit local conditions) by engineers at various mines and manufacturing plants. The mold is readily constructed as follows: It is made from two pieces of ½-in. sheet iron which can be turned up in a lathe, the faces being machined so that they form a perfect joint when placed together; otherwise the hot metal would work out through the joint of the mold. The size of the mold depends on the size of the boiler handhole. If the boiler has 4-in. tubes, then the handhole will be slightly larger. In this case the mold will be about 6½ in. in extreme diameter. As shown in the illustration, the two parts of this mold are practically duplicates of each other. A square-cornered shallow circular groove is formed in each face, about ⅜ in. wide and $\frac{1}{16}$ in. deep, the inside diameter of the groove being 4¼ in. and the outside diameter 5 inches.

Each part of the mold, as shown in detail, has a handle. The handle *A* is made of a ¾-in. bolt flattened so that it can be held in a bench vise. It is screwed through one part of the mold. The projecting end is machined free of threads and is used for a dowel or centering pin, snugly fitting a hole in the other part of the mold. The handle *B* can be made of wood, asbestos, or any other substance that does not conduct heat readily. When assembled the two parts of the mold are held in position as shown. An aperture is provided in the mold for receiving the molten metal, a passage ½ to ¾ in. wide and the same depth in each half of the mold as the depth of the gasket mold, being large enough.

Having a mold, crucible and lead, small ladle and a small pick, we are ready to begin operations. The pick shown in the illustration is used to free the gasket from the mold. A small ladle is preferable for pouring, as it can be handled more easily than a large one. After the lead has been melted, it is good practice to submerge the mold in the hot metal until the mold is hot enough to prevent the lead from chilling when it is poured. If the mold is heated to the same temperature as the molten metal, the lead will not "freeze." A little experience will familiarize anyone with these small but quite important details. However, success depends upon the following point more than anything else: When pouring, work fast. Do not forget to oil the mold after using it; this will keep it in good condition until the next time it is to be used. Schemes of this kind not only may save money for manufactured supplies, but there are often odd times when men about a plant can fill out a day on a little job of this kind.



To Counteract Effect of Acid Water

Slaked lime, introduced into the breaker "wash water" cistern at regular intervals, is the latest method being tried at several anthracite collieries to counteract the acids and effect a saving of shaker plates and chute linings. Where the fall of coal in transit through the breaker is not too great, it has been found practical to use terra cotta plates, 1¼ x 12 x 24 in. for chute lining. They give better results than tank steel and are practically acid-proof. They cannot be used where heavy lumps are handled at high speed.

Mirror Attachment for Safety Lamp

By Gaston F. Libiez
Peru, Illinois

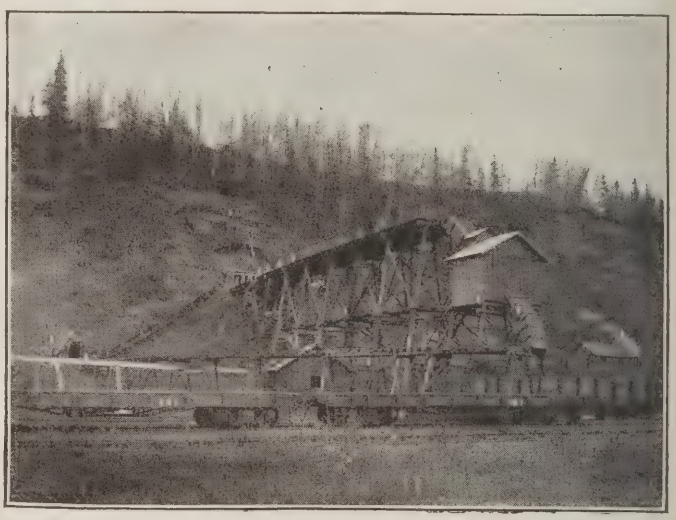
When testing for gas with a small flame on the safety lamp, it is difficult to watch the flame with a lamp raised to arm's length, as for instance, when testing in

SMALL MIRROR REFLECTS ANY MOVEMENT OF FLAME

a roof pocket. A small tilting mirror attached at the side and over the glass-protecting standards, as shown in the accompanying illustration, will reflect any movement of the flame without tilting the lamp.

Reserve Coal Deposits Are Blocked Out at Government Mine at Eska, Alaska*

By Sumner S. Smith
Alaskan Engineering Commission, Eska, Alaska



SUFFICIENT reserve coal deposits have been blocked out at the coal mine operated by the Alaskan Engineering Commission at Eska, Alaska, to insure an adequate fuel supply for several years. Further prospecting continues in order to determine the regular areas of both the Eska and Chickaloon mines and to discover, if possible, other and better beds of coal. The output at present has been raised to a point high enough to insure an ample supply of fuel for all operation and construction purposes and to build up a surplus large enough to protect against delays due to interrupted traffic and accidents at the mining property.

Five additional acres have been cleared in the Eska townsite, three new houses completed and a gravity water system installed. The electric light plant has been moved from its location on the townsite to a point near the Eska mine opening and a 25-hp. boiler added, giving a power capacity large enough to care for all lights and operate the three fans, which are steam-driven. The high-line grade has been ballasted and the cleaning plant completed.

The general structure at Eska is synclinal although there are faults parallel to and at various angles to the axis of the syncline which obscure much of the structural detail. The surface of the area under consideration slopes gently toward the south, the waters of Eska Creek, which drop approximately 400 ft. in three miles, cutting a valley from 20 to 200 ft. below the general level of the ground. As the coal measures were folded and broken long before the formation of the present topography, the beds are not parallel to the surface. They appear in the bluffs which form the sides of the creek as a series of rather distorted semi-circles, one above another, the lower portion of the arms being concealed by the débris on the bank and in the creek bottom.

There is no doubt that the drainage of this field has followed, in many instances, the lines of least resistance created by fault zones and it therefore follows that the pioneer mining which has naturally started upon the outcrops exposed by stream valleys will, in general, be in the most disturbed portions of the district. A particular example of this can be noted on the Shaw East or Emery maps where the overlying Emery bed has been thrown down opposite the Shaw and Eska. Here the Shaw and Eska on the west side of the fault dip about 45 deg. while the portion of the Emery opposite them is nearer the center of the syncline and has a dip of about 10 deg. On a map showing the surface topography it can be noticed that a small stream follows the approximate course of this fault. Toward the westward the structure seems to be more regular and probably attains its maximum uniformity under the Eska conglomerate.

The prospecting has consisted of churn drilling, open-cutting, driving a few crosscuts and sinking some shallow test pits. At the face of the Maitland the bed was cut off by a fault when the property was taken over by the Commission, so this entry was driven through the fault in an effort to locate the coal. When the entry had passed through the break it was noted that the movement of the ground had been such as to throw the extension of the bed east of the fault above the entry. The surface above this point, and to the eastward, was laid off in 200-ft. squares, and churn drilling started in an effort to locate the extension of this bed and obtain accurate information regarding the structure. Some 35 holes were sunk, the total drilling amounting to about 2300 ft. The results thus obtained were plotted on plates of glass which represented planes at right angles to the strata. The ground, however, was too irregular to draw accurate conclusions from the results of the drilling, although several coal beds

VIEW OF SURFACE PLANT AT CHICKALOON

were intersected which will be prospected later from the David workings. The drilling was difficult owing to the large number of boulders, and with the light rig used it was impossible to attain a depth much over 175 ft. The greater portion of the time the holes were much under that figure.

On the southern limb of the syncline the outcrops of the Maitland, Emery and David have been exposed on the east bank of the creek, and on the west bank the outcrops of the same beds have been opened on the northern limb of the syncline.

A prospect shaft about 50 ft. deep and crosscut just north of the townsite, which were driven to check some of the drill holes, opened the Shaw bed on the southern limb of the syncline, while several unnamed beds to the westward have been exposed by open cuts along the creek banks.

Inasmuch as there are six different beds all of different thickness under exploration at Eska, and as the dip varies from 10 deg. to 60 deg., no one method

*Reprinted from *Alaska Railroad Record*, Vol. III, No. 20.

TYPES OF COTTAGES AT ESKA COAL MINES

of extraction can be applied to the entire series. However, all the coal so far produced has been recovered by the room-and-pillar method, the room width, in general, being 20 ft. with 30-ft. pillars between. There have been slight variations to this rule occasionally, due to the faulted or broken condition of the ground. All of the rooms are run on sights, and where the beds are parallel the pillars of the upper beds are kept vertically over those of the lower.

In new developments the practice is to drive the main haulageway and airway on the coal, the airway being about 30 ft. above the entry. An 8-ft. chute, 4 ft. of which is used for a manway, is driven every 50 ft. to connect the entry and airway, providing for ventilation and supplying storage room for the coal.

The rooms are turned off the airway opposite each chute. For 15 ft. they are driven up 8 ft. wide and then widened to 20 ft., at which measurement they are driven to the boundary.

The standard entry is 6 ft. wide at the top, 9 at the bottom, and 6½ above the rail. These measurements are in the clear.

Round timbers are used on the entries with 2 x 6 sawed lagging, the sets being placed on 6-ft. centers. In the rooms and pillars split cottonwood posts are used and have proved very satisfactory.

No coal is shot off the solid, but is undermined or cut at one side of the room before any shots are fired. The room-and-pillar method, with the rooms driven straight up the pitch, was adopted because the demand for coal was acute and this offered the greatest immediate supply. At some future date it will be possible to experiment with other methods, although the recovery so far has been excellent; and it is doubtful if any other method would give as satisfactory results, as the system is flexible and lends itself readily to the varying conditions met underground.

The methods of handling the coal from the face to the entry vary according to the thickness of the coal and the dip of the bed. When the pitch is steep enough for the coal to run on sheet iron, a chute is carried up the room with a manway and the coal is drawn from the chute into mine cars on the entry. Where the dip is low and the beds thin, small mine cars are installed to save brushing top or bottom. A sheave with a brake is fastened near the face of the room, a double track laid from the switch on the entry, and the weight of the loads used to pull the empties to the face. At several points where the dip is variable, a combination of the two systems is necessary, the small mine cars being emptied into a large loading chute on the counter and the coal transferred to larger cars on the main entry.

Owing to the excessive cold and the resulting difficulty of keeping the tracks underground free from ice during the winter months, the main haulageways have been made the return airways. During the winter of 1917-18 the only fans available were too small to overcome the natural draft, the result being that the cold air entering the main haulageway froze the water in the chutes and along the tracks. This lessened the production and practically doubled the cost of operation.

To ventilate the west side of the mine a 200-ft. crosscut was driven which intersected the main haulageway about 150 ft. from the portal. Two doors were placed on the haulageway between its portal and the intersection with the crosscut and a 3 x 2-ft. Jeffrey all-steel, double inlet, exhaust, reversible fan erected at the portal of the crosscut.

During the winter the air is taken in the counter gangway and distributed by three splits to the Eska, Shaw and Martin beds. This raises the temperature of the air considerably above the freezing point and keeps the temperature along the main workings fairly constant both winter and summer. The water is drained to a sump in the crosscut near the fan and the exhaust from the fan engine turned into the sump. This raises the temperature of the water to a point where it can be conducted to the outside without danger of freezing the drain boxes. The fan is driven by a 5 x 5-in. engine taken from an old Star drill, and under the present conditions has a capacity of about 15,000 cu.ft. of free air per minute. During the summer the air is admitted to the workings by chutes driven to the surface, the natural ventilation acting directly with the fan.

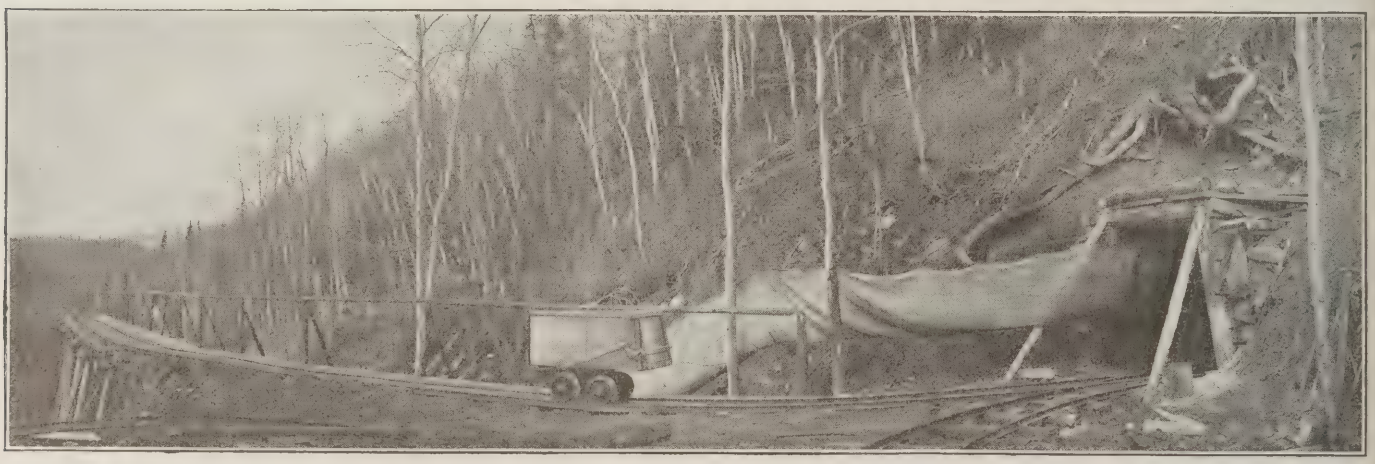
On the east side of the creek the old Shaw entry was extended to the surface and a 4 x 2½-ft. Jeffrey, all-steel, double-inlet, exhaust, reversible fan erected at its portal to ventilate the Emery, David and possibly a portion of the Maitland workings. The air for the David will be taken through the David airway and for the Emery through the Shaw counter. The fan is driven by a 6 x 7-in. vertical engine and has a rated capacity of 50,000 cu.ft. of free air per minute.

The Maitland is ventilated through a back entry on the coal which taps the main haulageway about 50 ft. from the portal, the intake air coming into the

VIEW OF SURFACE PLANT AT ESKA

mine through room No. 5, which is open to the surface. The air current is produced by a Western Blower Co. fan, which has a 24-in. intake, driven by a 5 x 5-in. engine taken from an old Star drill. This has a capacity of about 2000 cu.ft. of air per minute during the winter when conditions are most severe. The arrangements as regards drainage in the Maitland and Eska east drifts are similar to those on the west side, and all the fans are fitted with explosion doors.

During the summer a 20 x 40-ft. building was erected for a power plant near the mine entrance on the east side of the creek. The electric lighting plant which was formerly situated on the townsite was moved to the new building and a duplicate boiler added. The plant now contains two 42-in. vertical boilers which furnish steam for the fan and dynamo engines. The electric lighting equipment consists of a 15-kw. generator belted to a 7 x 8-in. Clark engine, the current being distributed at a pressure of 220 volts.



The coal from the mine is hauled over a highline some distance to the cleaning plant, where it passes over a ¾-in. grizzly to a picking table. As the grizzly did not remove all the undersize a 3-ft. section of ¾-in. slotted screen was set in the upper end of the table to take out the balance. The coal chutes are so arranged that the under and over-size may be loaded in the same or separate cars according to the use to which the fuel is to be put. As the coal is quite friable the undersize is the purer of the two products before the lump is cleaned and makes a good grade of fuel for power-plant work. It could be considerably improved by washing, but the present developments do not warrant the expense of installing such a plant.

During the year the Martin and Eska west entries have each been driven over a thousand feet and chutes raised from the Martin entry to the Shaw counter. From the Eska east a connection has been made with the Emery east on the northern limb of the syncline and a crosscut started that will tap the David in the same relative position. The latter beds are parallel to and underlie the Maitland. On the east bank of the creek the outcrops of the Maitland, David and Emery have been pinched up on the southern limb of the syncline, and on the west bank the same beds have been found on the northern limb. The outcrops of the Eska and several unknown beds have been picked up to the south and west, but as the extent of those beds has not been determined, the available tonnage cannot be estimated.

Considering only those areas that are above the present levels, there was on Jan. 1, 1918, approximately 22,000 short tons of coal available. During the year the commission has mined some 56,000 tons and on Jan. 1, 1919, there were 145,000 tons available for mining from the present openings.

The system of cost accounting is exact and comparatively simple. All material coming to the mine, whether from the main commission store or from private contractors, as the mine timbers are secured, is charged into a mine stores account. The storekeeper is directly responsible for all material and equipment, and issues the same only on the requisition from proper authority, such requisition showing where the material is used. All the material used is charged from the mine stores account direct against the place where it is used. All explosives are distributed to the place of use and record made of the same by a licensed powderman who reports such distribution daily. All material and equipment used must be requisitioned and a daily report of its use made by the foreman in immediate charge of the work.

With the exception of monthly bills from other departments the exact distribution of costs is obtained daily and is so arranged as to show at any time the material and labor entering any job, its progress at any date, and its present status.

SHAFT ENTRANCE OF THE ALASKA ENGINEERING COMMISSION MINE AT CHICKALOON

During the year there have been eight slight, five serious and no fatal accidents. There were approximately 57,000 man-shifts worked both surface and underground. The time lost due to accidents amounted to 30½ shifts for the slight accidents and 148 shifts for the serious.

At the time of the influenza epidemic one of the bunkhouses was converted into a temporary hospital. There were 55 cases, three of which developed into pneumonia and resulted in the death of those afflicted.

ALL HOISTING ENGINEERS are familiar with the stretching which takes place in new wire ropes on slopes and shafts, and the reason is obvious. A bundle of spiral springs will stretch much more than would a bundle of the same number and size of straight wires. Under tension these springs stretch out. This action is interfered with somewhat on account of the wires and strands being tightly twisted together. However, if the core is of hemp the strands press down upon this elastic center and the rope stretches more or less. There is no special objection to this, for the engineer recognizes that it takes place and changes the landing marks on his rope or dial accordingly.

Preparation of Bituminous Coal—I

By Ernst Prochaska
Benton, Illinois

SYNOPSIS—*Coal must be sold for more than it costs to produce, else the producer goes out of business. Preparation either raises the selling price or increases sales. Many types of preparation plants have been tried, some with success and others without it. For best results it would appear that final screening should be done after washing.*

THE existence of every coal mine depends solely upon the selling price of its product exceeding the cost of production. It may be feasible to operate a washery or a screening plant in connection with a coal mine if the better price obtained for the cleaner coal equals the cost of operation; or these plants may be operated at a loss, if thereby part of the mine output can be made salable or its sales increased.

Under the last named conditions, however, the preparing plant is only a necessary evil put in to satisfy the consumers. The management will be inclined therefore to make this plant as small and as simple as possible. If, however, the difference between the selling prices of raw coal and prepared coal is greater than the cost of preparation, the preparation equipment is coöperating with the mine to get a bigger profit for the whole mining plant; and the management will energetically use every effort to improve the method of preparation, to increase the difference between cost and selling price by decreasing the cost of preparation and by producing a high-grade prepared coal.

Early Preparation Plants Forced Upon Operators

The foregoing facts are now well known, but it took a long time before the coal industry was fully convinced. The first preparation plants were not installed for the purpose of increasing the profits of a mine but were forced upon the coal industry by the demands of the consumers for a better product. The first demands for cleaner coal were made by the blast-furnace men who wanted a coke with less ash. This demand for a cleaner coal was restricted to comparatively few localities, and it was only after it had been thoroughly demonstrated that the greatest benefit accruing from coal preparation lay in the possibility of increasing the value of the coal and thereby the selling price far above the cost of preparation, that the coal industry took hold of this problem.

Besides the visible advantage of a larger profit, the economic question of the fuel supply commenced to be understood. It was plainly visible that a properly functioning separation plant could permit the mining of a coal bed, the coal from which on account of its large percentage of impurities could not be sold in the raw state. The experience with coal-preparing plants has established the following maxims:

1. The preparation of coal shall, by the cleaning of the raw material and the production of suitable and well screened sizes, secure a maximum price per ton of output.

2. To arrive at this result three points must be kept in view: (a) Highest possible purity of coal; (b) smallest possible loss of coal; (c) small cost of production.

3. As the foregoing three demands are conflicting, it will be necessary for the proper and economical installation of a preparation plant to find in each case the best relation between the three factors.

The maxim of loading the coal as clean as possible has been known and practiced to a greater or less extent since coal has been mined. As early as the first quarter of the last century slate was picked out of the coal in the mine and gobbed. The miners' wages were adjusted according to the purity of the coal loaded, and docking has been in use for the last 50 years.

Dry separation is usually accomplished with screens and the methods of screening can be separated into two groups: The first deals with screens for the purpose of making lump coal and screenings only; the second deals with screens that classify the product into lump, egg, nut and different sizes of screenings. The first group belongs solely to the dry separation process, whereas the second group belongs to it only if all the coal is prepared in a dry state. If a washery is connected with the mine the classification screens belong properly to the washing plant.

Mechanical Preparation of Fine Coal

At present the preparation of the fine coal is carried on with water, and mostly in jigs. But in the beginning many processes were devised to avoid the use of water, and even now many inventors are working on the solution of a dry separation process. The wet separation always has had a decided advantage.

Before we enter into the description of this process we must consider the development of the classification of fine coal. Two different opinions in regard to the proper way of carrying on screening has always existed: (1) Screening from coarse to fine and (2) screening from fine to coarse. There also exists the question of whether it is better to screen before washing or to wash first and then screen.

In the beginning screening from fine to coarse was preferred. It was the shortest method and had the advantage that the dust was removed on the first screen plate, or that having the smallest perforations. But it had the drawback that the fine screens wore out quickly on account of the large mass of coal passing over them, and furthermore this large mass of big coal did not permit perfect screening. Both these disadvantages became greater as the quantities to be handled increased. In the sixties of the last century the practice reversed itself completely and most screening was done with concentric revolving screens. This method, however, did not remain long in actual practice. The demand was for a method of screening that would give output, durability and simplicity combined. These three demands were fulfilled by the shaking screen and later by the vibrating screen.

As long as jigging was performed on hand jigs nobody thought about classifying the coal. This, however, was not because the operator was convinced of the cor-

rectness of his method, but because at that time only the simplest and cheapest pieces of apparatus were used. Later on, after the jigs were improved, it was found that the separation was not particularly close and lack of sizing was blamed therefor. Since in ore dressing plants close classification was considered necessary, this was followed also in the coal washeries.

At first this was carried too far, and even the fine coal was divided into three or four sizes. But later on it was found that this close sizing produced too tight a bed in the jigs and it became necessary to mix in some nut coal. Nevertheless sizing apparatus remained a part of the equipment of every washery. The screening of the coal, however, was troublesome and made the washery complicated. Later on the coal was not so closely sized and some washeries were built to treat unsized material. The demand for well-screened washed coal, however, made it necessary to screen the coal after washing and consequently the coal was only screened into two sizes before wet treatment. Baum was the first to use the slogan "Washing before screening." Stewart also washed coal from 3 in. in diameter down without further sizing. In fact the great majority of coal washeries in America are washing unsized coal.

The knowledge gained by past experience can be condensed into the following paragraphs:

The jigging of bituminous coal can be carried on successfully without preparatory sizing.

Experience has shown that the separate washing of the fines facilitates the washing process and gives slightly better results. It has been proved, however, that coal finer than 20 mesh can not be improved by washing and should, if low enough in ash, be mixed with the washed coal; or if too high in ash used for other purposes.

The advisability of sizing the larger pieces of coal before washing must be judged for each installation separately.

To produce a perfectly sized washed coal screening after washing is necessary.

The whole question, where favorable raw coal is involved, it not of decided importance. It must be determined in most cases by considering the cost of installation and operation, the space required and at disposal, and the most suitable general arrangement of the plant.

Washing of Coal

The following types of apparatus have been used for the washing of coal: Trough washers, ascending current washers, jigs with stationary and with moving screens, concentrating tables, air separators, centrifugal separators, separators using dense liquids, separators taking advantage of the different shapes of the particles, and chemical washers. The results obtained with these methods and types of apparatus can be summarized as follows:

Trough washers are only adapted for the very fine coal or for the removal of fireclay and mud.

Ascending current washers deserve the credit of having opened the eyes of the coal operators to the benefit derived from improving the coal by washing, but on account of low efficiency they have been supplanted by jigging which owing to its simplicity and satisfactory efficiency is far ahead of all other methods.

Tables are being used especially for the fine coal to good advantage, and the results obtained with them are highly satisfactory.

Air separators are important for the purpose of removing and collecting the dust.

Centrifugal separators can not compete with the other methods, but centrifugal force is used to some extent for the drying of coal.

Dense liquid separators have proved failures.

Separation according to the shape of particles is to be considered only in special cases. It can be used as a preparatory process.

Chemical washers have not been sufficiently tried out in actual practice, but they appear to be cumbersome and costly.

The products resulting from the foregoing operations, if wet processes only are considered, are washed coal from 3 in. down and dirty wash water containing fireclay and sludge. It always has been clear that both of these products need further treatment before they can be used to the fullest advantage. The washed coal must be dewatered and the wash water must be clarified and the sludge removed. This clarification must be carried on to such an extent that the water can be either returned into the system to be used over again or that it can be let run away without polluting streams and natural water courses.

Dewatering of the Washed Coal

The dewatering of the larger sizes of washed coal is comparatively simple and easy. It is usually carried out on dewatering elevators, which are used to elevate the washed coal into the loading bins. Further dewatering is also carried on on the screens that are employed to size the washed coal.

The dewatering, or rather drying, of the fine coal is a much more difficult problem. Fine coal if wet forms a dense, compact mass which contains too much water for use in either coke ovens or boiler furnaces. The wet coal has also the further disadvantage of freezing solid in the winter time. The excess water increases the weight of the coal and most consumers object to paying coal prices for moisture. The drying of the fine coal has for a long time been a sore point, and even now it presents great difficulties. For this reason it was proposed to screen out all coal below $\frac{1}{8}$ in. and mix the raw fines with the washed fuel.

This method offers the simplest solution of the difficult drying problem, but can only be used if the ash and sulphur content of the washed coal are thereby not materially increased. This, however, is hardly to be expected, as no material improvement can be accomplished by washing fines below 10 mesh. If, however, the addition of the raw fines should increase the ash and sulphur in the washed coal above a desired amount, it would be better to load the fines in the raw state, or to use them for fuel purposes.

There are at present four methods of drying coal particles smaller than $\frac{1}{2}$ in. in diameter: Dewatering pits, centrifugal dryers, heat dryers and filters.

Dewatering pits have been used to some extent. They required considerable ground space, are costly to install, and the operation expenses are also rather high. The dewatering of the coal is only effective to a certain depth, as the material in the lower portion of the pits acts as a filter bed and must in some instances be removed and rewashed.

Centrifugal dryers are at present the most satisfactory apparatus with which to dewater coal. The operating costs are reasonable and the coal is dewatered to a fairly satisfactory degree. The only objection to this

type of dryer lies in the fact that it produces too much sludge. This requires additional apparatus for its recovery.

Drying by heat can not be considered on account of the high cost for fuel.

Filtering can only be considered for very fine coal and sludge. It should, however, give good results. Up to the present time no extensive filtering plants have been installed in any of the coal washeries.

(To be continued)

Some Items That Enter Into the Cost of Producing Coal

The many little factors that enter into the cost of producing and marketing coal have been rather clearly defined during the last few years. As a result of investigations made by the Fuel Administration, the operators, during the war period, were obliged to submit itemized monthly reports of the tonnage and cost of producing the coal shipped from their respective mines. The major part of the expense in producing coal is incurred in mining, haulage, pumping, ventilation, timbering and supplies. It is with the item of supplies that this article will deal.

The Victor American Fuel Co., with eight producing mines in the State of Colorado, submitted a statement recently showing some of its sundry expenditures during the year 1918. This company produced 1,142,891 tons of coal last year, which is about one-tenth of the total tonnage of the state. Machine-mining has not progressed to the same extent in Colorado as it has in other states. The company in question in 1917 mined around 700,000 tons of coal by hand and 200,000 by machine. The Victor-American operations using hand mining exclusively in 1917 were Ravenwood, Bowen, Gray Creek and Wadge; these mining largely by hand were Delagua and Pinnacle, and those mining largely by machine were Chandler and Radiant.

This company used 130 horses and mules, 28 electric motors and 20 electric mining machines in the year 1918. The total capacity of the eight mines is 6250 tons per day, and the largest producer of the group is Delagua, with 2500 tons; Pinnacle follows with a capacity of 1000 tons. The tonnage of the various plants for 1918 is as follows: Delagua, 555,688; Chandler, 177,013; Pinnacle, 130,143; Bowen, 102,143; Ravenwood, 58,876; Radiant, 43,474; Wadge, 40,004, and Gray Creek, 35,549. All these mines are nongaseous. Chandler is a shaft mine, the seam being 461 ft. below the surface; the other plants are either slope or drift operations. In 1917 this company had 916 inside employees.

The Victor-American statement referred to distributes certain expenditures for its eight operations under 36 items. The accompanying table gives a selected list of these items. The figures in the table represent these items reduced to a cost-per-ton basis of the coal produced at each mine in 1918. As local causes affect such costs, a better plan would be to give an average covering several years. For instance, in a certain year enough rail may be purchased to nearly last during the following year. Such matters as hay and oats also may vary somewhat; thus at Delagua, a greater number of mules are used for haulage than at mines like Pinnacle and Wadge, where so much of the haulage is mechanical.

Operators should find this table interesting for comparison with their own costs, making due allowance for differences of coal field and section of country. The statements made as to the equipment of the various mines and their capacity should throw quite some light on the subject. Where there is considerable variation in the cost per ton for the same item among the several mines, there is a special reason for it. Thus, in the case of mine timber and ties, the cost varies all the way from 3½c. to 27c. per ton of coal produced. Unless there was an unusual or temporary demand for the excessive use of timber at some mine, we would expect to account for this irregularity by the fact that large quantities of timber and ties had been purchased looking ahead to future requirements. Similarly in the case of rails and fastenings. In this connection custom differs among operators. Some companies charge up the full amount of a big purchase of equipment at the time the bill was settled, thus cleaning up the account at once. Others distribute the cost of such purchases over a greater or less period of time. By this latter method the monthly cost sheets do not show such wide variation in the cost of producing coal. They more nearly represent the true condition of affairs.

There is also considerable difference in the totals of the cost of supplies per ton of coal at the various mines, the average being $0.2295 for the eight mines. In five of the operations the total runs from 10½ to 17 or 18c., which would seem to give a fair idea of the cost per ton of coal produced for the items charged.

SOME ITEMS ENTERING INTO THE COST OF PRODUCING COAL AT THE MINES OF THE VICTOR-AMERICAN FUEL CO.

The Future of Peat as a Fuel—II

By J. B. C. Kershaw
Colwyn Bay, North Wales

SYNOPSIS—*Raw peat, even when commercially dry, is hardly a satisfactory fuel for power purposes. Various methods have been employed for carbonizing and gasifying this fuel, in efforts more or less successful; one successful method of burning peat so far as steam generation is concerned is by powdering it and burning the powder in suspension. Gasification and powdering appear to be the routes of improvement along which may be expected the greatest future progress in peat utilization.*

MANY processes have been devised and patented for carbonizing peat in closed retorts or ovens, the aim being to obtain a more condensed and marketable form of fuel than is obtained by briquetting, or by machine treatment of the raw peat. In these processes the air-dried machine-treated peat, obtained as described in Article I, is employed as the raw material for a further process of enrichment, artificial heat being employed to drive off the remaining moisture and some of the hydrocarbon gases.

None of these processes has yet obtained general application, for the simple reason that, in the majority of cases, the increase in the calorific value of the chief product—peat coke—and the value of the recovered byproducts is not sufficient to cover the cost of the additional treatment. Under special conditions as regards the market for peat coke, and for the creosote, light oils, acetate of lime and other byproducts, the peat-carbonizing processes can be worked successfully, however, and both in Norway and Germany there are installations of this type in actual operation. The processes are distinguished as "dry" or "wet" carbonization processes according to whether dry heat or superheated steam is employed.

The Jebson process of dry carbonization is based upon the application of electrically produced heat and was first worked upon an industrial scale in the years 1901-1902, near Bergen, in Norway. So far as I am aware it is still employed at this place, but it does not appear to have made headway in any other locality.

The peat, dried as far as possible by the sun and air, is molded into suitably shaped blocks and is placed in retorts the walls of which are covered with asbestos or other non-conducting material unacted upon by the gases which are produced when the peat is heated. The charge of peat is then raised to 450 deg. C. (842 deg. F.) by means of electric resistance coils placed inside the retort in contact with the raw peat, so that the heat produced in them is transmitted directly to the charge, without any losses by convection or radiation.

By this means some of the difficulties of heating the charge of peat are overcome but the method is applicable only where electric power is available at a low cost, as is the case in Norway. The gas produced is used to dry the blocks of peat before they are placed in the retort, in a long heating chamber operated upon the countercurrent principle. The tar obtained is worked up for the usual byproducts of the peat-coking process.

The Ziegler method of carbonizing peat in closed retorts was brought out by Dr. M. Ziegler in 1892, and has been worked successfully since that year at several localities in Germany and Russia. The peat in this case is carbonized by the application of artificial heat, obtained by burning the gas given off from the retorts. Where the process is most successfully operated the surplus gas suffices to generate power for operating the dredging and pulping machines by aid of which the peat is won from the bog, while the waste heat of the gas which passes away from the retorts is also utilized to dry the peat blocks before carbonizing.

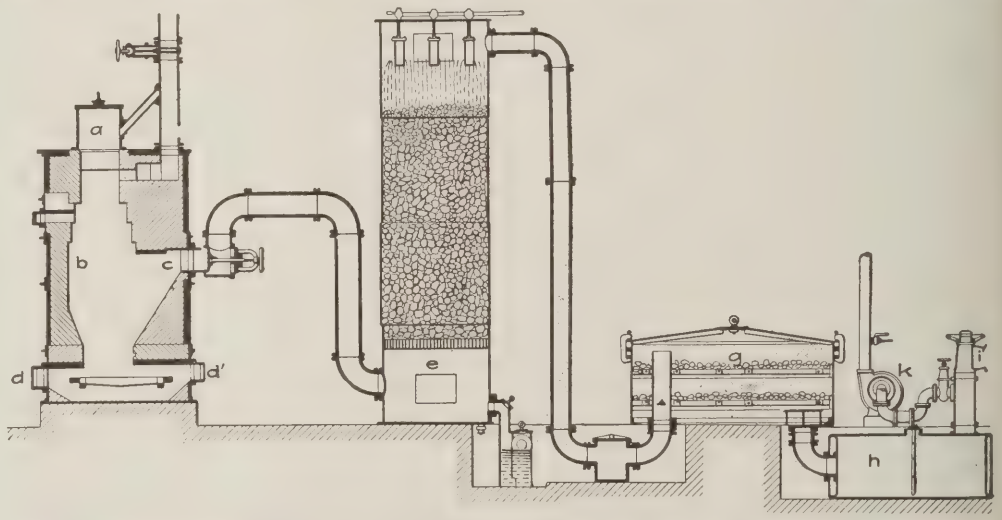

FIG. 7. SECTIONAL ELEVATION OF PEAT GAS PRODUCER, SCRUBBER, DRIER AND FAN—GAS OUTLET AT SIDE OF PRODUCER

As regards the output of solid fuel by the dry coking process, about one-third of the weight of the raw peat charged into the retorts is obtained as a "peat coke," specially suitable for blacksmithing and metallurgical work, on account of its low content of sulphur and ash. According to an estimate made by Dr. Ziegler, the yield of byproducts from a plant coking 100 tons of air-dried machine peat each 24 hours will be as follows: Creosote oil, 3100 lb.; acetate of lime, 1320 lb.; sulphate of ammonia, 900 lb.; paraffin wax, 715 lb.; pitch, 440 lb.; light oils, 280 gal.; heavy oils, 95 gal.; methyl alcohol, 65 gal.

This estimate, however, is only correct for the peat found in the locality where the plant which gave this yield is situated, and it is important to note that the financial success of the Ziegler process is highly dependent upon the character and the purity of the peat charged into the retorts. The existence of good markets near at hand for the peat coke and byproducts of

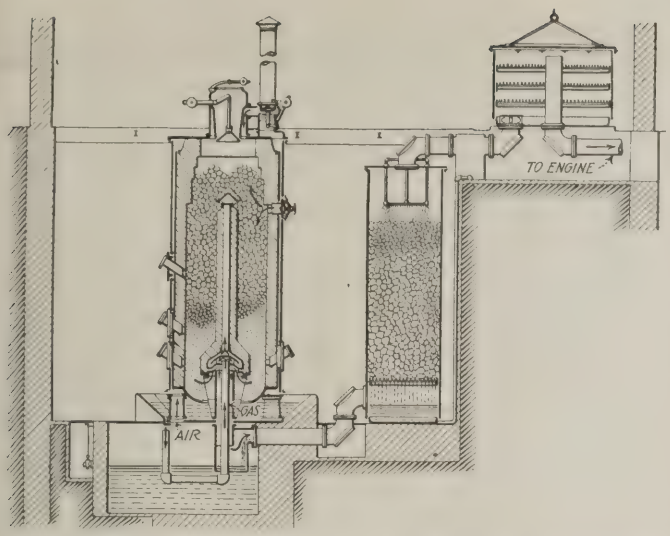

FIG. 8. SECTIONAL ELEVATION OF PEAT GAS PRODUCER, SCRUBBER AND DRIER—GAS OUTLET AT BOTTOM OF PRODUCER

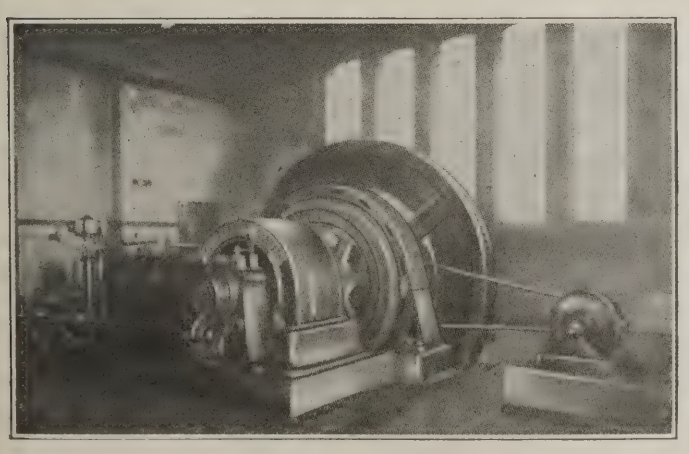
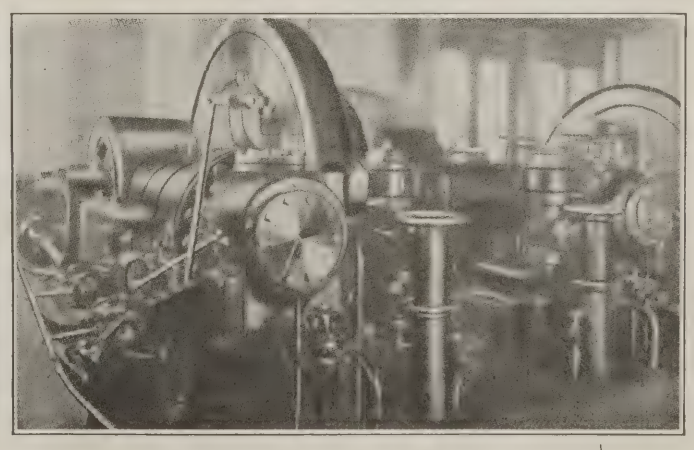
the process is also a *sine qua non* of its successful operation. The Ziegler plants erected in Europe were at Oldenburg and Reuerberg, in Germany, and at Redleino, in Russia; but the last named is reported to have not achieved a permanent success, owing to lack of demand for the byproducts.

That the Germans are still devoting attention to the dry distillation of peat is shown by the fact that as recently as 1916 a patent was granted to Limbers (No. 302,322, Nov. 3, 1916), for an improved form of retort in which the heating is to be effected in three stages by means of heated non-oxidizing gases, which pass over and through the mass of fuel.



The "wet" carbonizing processes depend upon the use of superheated steam under considerable pressure for raising the temperature of the peat to 300 to 400 deg. F. It is doubtful if any real carbonization occurs at this temperature, and it is much more probable that the hardening effect of the treatment upon the peat is due to the breaking down of some portions of the cell structure, and to the fact that more of the water and moisture can be expelled afterward by mechanical pressure than is the case with ordinary machine peat.



The most noteworthy of these processes of peat carbonization was the Ekenberg process, which was brought out in 1904 and was tried upon a working industrial scale in Sweden. The wet carbonizing furnaces used in the trials consisted of a series of iron pipes about 36 ft. long, through which the wet peat, in the form of finely divided pulp, was forced at a pressure of 150 lb. per square inch. Each tube was double, and the peat pulp after passing down the large outer tube returned along the inner smaller tube and thus gave up some of its heat to the incoming pulp. The outer tubes projected for half of their length into the firebox of the furnace and were heated here to the required temperature by coal or gas. Ekenberg claimed that this heating under pressure destroyed the cells of the slimy hydro-cellulose compounds, which inclosed a large proportion of the water contained in the peat, and that after submitting the material to his process the greater portion of the water could be expelled by mechanical pressure alone.

The water-free carbonized peat tested 11,000 B.t.u. per lb., and the cost of production was estimated to be from $1.60 to $2.10 per ton, according to whether machine or hand labor was employed for winning the peat from the bog. Although the Ekenberg process received an extended trial in Sweden, and was much discussed by engineers, having been the subject of a paper read by the inventor before the Iron and Steel Institute in 1909, I believe that it is not now in operation, the costs having proved excessive.

A modification of the process has, however, been introduced into France, and has been operated successfully in the development of the peat deposits at Ille-et-Vilaine. The following description of the process is taken from an article by Messrs. Galaine, Lenormand and Houlbert which appeared in *Comptes-Rendus*, of Sept. 3, 1917:

The peat is first treated in presses of the Mabille or Aurep type, which give a pressure of 710 to 1420 lb. per square inch and easily reduce the original water contents of from 80 or 90 to 60 per cent. The partially dried peat blocks, or turves, are then placed in a suitable carrier and are introduced into horizontal autoclaves, where they are heated by steam to 160 deg. C. (320 deg. F.) for a period of 25 minutes. On removal from the autoclaves the hot briquets may be a second time passed through the press, but this is not essential. They dry quickly in air down to 20 to 25 per cent. of water, but it is better to place them in a heated chamber for the final stage of the process. The final product is quite different in physical and chemical properties from briquets of ordinary peat, and the authors have given it the name of "tourbon." They regard it as a half-formed coke, and state that its heat value is about 13,000 B.t.u. per pound, or considerably higher than that of dried peat. As the hydro-cellulose compounds have

FIGS. 9 AND 10. VIEWS IN ENGINE ROOM OF PLANT SHOWN IN SECTION IN FIG. 7

been destroyed by the temperature attained in the autoclave, the product does not absorb more moisture after it is once dried.

An approximate analysis of the anhydrous *tourbon* obtained from the peat deposits of Châteauneuf, at Ille-et-Vilaine, gave the following figures: Volatile matter, 60.3 per cent.; fixed carbon, 36.6 per cent.; ash, 3.1 per cent.

By arranging the autoclaves in batteries, with suitable arrangements for making use of the heat of the exhaust steam, it is possible to carry out the process with an extremely high efficiency as regards utilization of the heat, the figures varying from 85 to 91 per cent.

Gas producers have been designed in recent years that can be operated quite successfully with solid fuels containing up to 35 per cent. of water, and this fact has led engineers to devote considerable attention to the possibilities of utilizing peat in gas producers. The fact that the low temperature obtaining in the producers favors the production and recovery of ammonia is another point in favor of the complete gasification of the peat, since the average nitrogen content of many

driving a modern gas engine, will yield the same amount of power at the engine shaft as one ton of good coal employed for steam raising and power generation in an up-to-date steam-driven power plant. In support of this statement the following figures are given, taken from an actual test carried out in Germany in 1911, with a 300-hp. suction gas producer and engine, using as fuel a peat testing 23.4 per cent. moisture, 4.2 per cent. ash and 7108 B.t.u. per pound.

The consumption of peat during the test was 2074 kg. (4560 lb.) at full load and 1736 kg. (3820 lb.) at half load, the consumption per horsepower being 0.99 kg. (2.18 lb.) and 1.45 kg. (3.2 lb.) respectively. The gas obtained from the producer at full load tested as follows: H, 17.15 per cent; CO, 15.85 per cent.; O, 1.02 per cent.; CO_2, 12.34 per cent.; N, 52.2 per cent. The calorific value of the gas was 120.2 B.t.u. per cubic foot. Assuming the air-dried peat could be delivered into the producer from the bog at a cost of $1 per ton, the cost of fuel per kilowatt-hour in this plant was only 0.154c., which is a far lower figure than could be obtained with any other fuel.

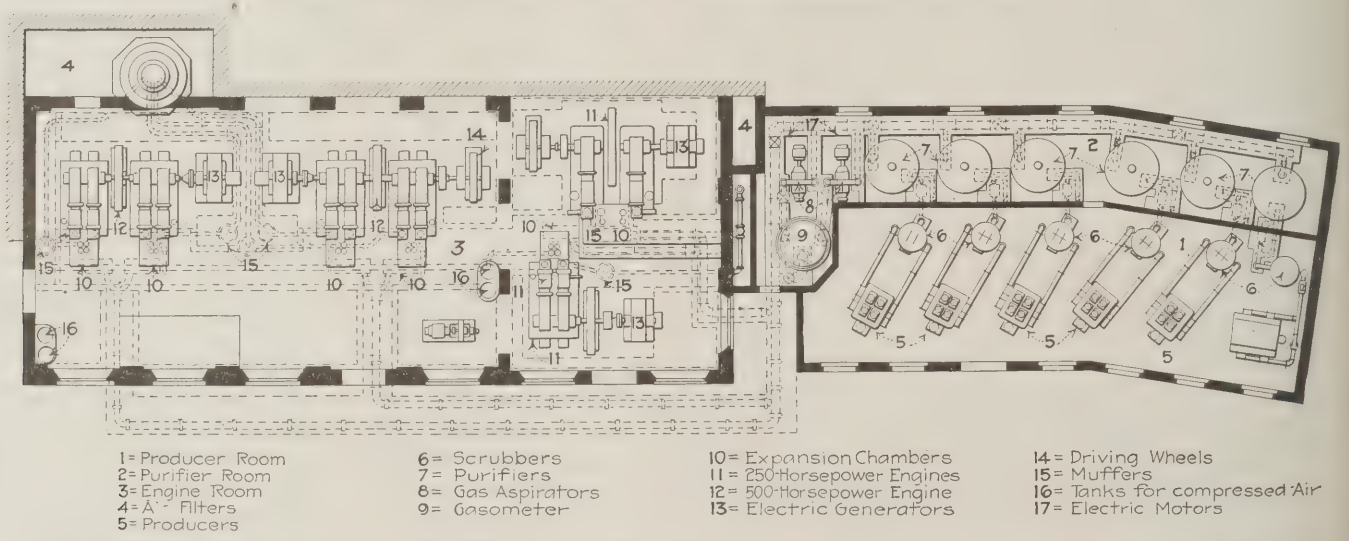


FIG. 11. PLAN OF ENLARGED POWER STATION AT VISBY, IN GOTHLAND, SWEDEN; GAS PRODUCER PLANT AT RIGHT, POWER PLANT AT LEFT

peat bogs is higher than that of the ordinary coal measures. Many forms of special producer and plant for the gasification of peat and recovery of the ammonia have been patented and tried upon an industrial scale in Europe during the past decade. Before the war there were quite a large number of these peat-gas power plants in successful operation in Germany, Sweden, Russia, Austria, Italy and Ireland.

The type of gas producer that has proved most satisfactory with peat is that known as the double combustion-zone producer, the gaseous products that collect above the charge of fuel being drawn (or forced) downward through the incandescent carbonaceous matter, in order to decompose the larger portion of the tarry vapor contained in these gases before they are used in the engine. Practical tests have proved that more power is obtained by this simple gasification process than when byproduct recovery is carried out. The decision as to whether there will be any economic gain by separating the tar and recovering the ammonia must depend upon local conditions, the amount of nitrogen contained in the raw peat and the size of the plant.

Under the best conditions one ton of peat gasified in a double-zone, suction gas producer, and utilized for

Some typical installations of peat-gas power plants will now be described. Fig. 7 shows a section of a peat gas producer with the gas outlet at the center of the producer. Fig. 8 shows one of the down-draft type with the gas exit at the bottom.

One of the earliest installations of a peat gas producer to be erected was that at Skabersjo, in Sweden. This plant was started in 1904 and enlarged in 1906 and, so far as I am aware, is still in operation. A large peat bog exists in this locality at a distance of only three miles from the town, which is supplied with electricity for heat and power purposes from the generating station at the bog. Fig. 7 is a sectional elevation of the producer, scrubber and fan, and Figs. 9 and 10 are views of the engine room. The original installation was designed to produce 150 hp. This proving to be quite successful, the plant was duplicated in 1906 and increased to 300-hp. capacity.

Only 750 tons of air-dried peat are required per annum to give this power, and there is consequently little difficulty in obtaining the peat from the bog, with the aid of the local farmers, during the working season, which in this locality lasts from Apr. 15 to Sept. 1. The power for working the dredger and pulping ma-

chine is obtained from a 35-hp. motor, supplied with electric current from the central generating station.

Two Koerting suction gas producers, specially designed for peat gasification, are installed at this station, with two 150-hp. Koerting gas engines of the twin horizontal single-acting type. These engines are direct-coupled to three-phase alternators which generate current at 3000 volts for transmission to the town of Skabersjo, where it is sold to consumers, for lighting purposes, at 9 cents per unit. The air-dried peat was delivered (before the war) to the producers at a cost of only $0.80 per ton, whereas bituminous coal at this place costs $3.80 per ton.

Another successful and larger peat-gas power installation, equipped with Koerting producers and engines, is in operation at the cement works situated at Visby, in Gothland. The original plant here was erected in 1908 and consisted of one 250-hp. producer and gas engine of the horizontal single-acting type, but in 1911 when Fernald[1] visited the plant, the equipment was being increased to 1500 hp. Fig. 11 shows the plan of the enlarged power station.

The peat-working season on the bog at Visby extends from Apr. 15 to Aug. 8, and all the peat required for the winter's use should be dry and in the storage bins by Oct. 1 of each year. The peat machine originally used in 1908 required 42 hp., and when worked with a squad of 10 men it produced 60 tons of "dry" peat per day of 10 hours. The term "dry," applied to this peat, was somewhat misleading, as it still contained 25 per cent. or more of water, according to the weather conditions prevailing when it was harvested.

With this machine the peat was excavated by a bucket dredger and conveyor, was passed through shredding and mixing devices, and was then delivered into the cars in a pasty mass. It was transported in this state to the drying fields and was dumped into a frame on the ground. It was finally rolled and divided into bricks by means of a bladed roller and a 3-in. disk cutter operated by a workman. This "dry" peat contained 25 to 40 per cent. moisture, and the bricks measured 8 to 10 in. in length, 4 in. in width and 2 in. in thickness, and weighed 1¾ lb. The cost of this peat when collected at the bog ready for delivery in cars to the gas producers, was $1.36 per ton.

Ireland—The most successful example of an industrial power-plant operated with peat, in Ireland, is that of Hamilton, Robb & Co., at Portadown, County Armagh. This plant has a capacity of 400 hp. and has been in continuous operation since 1911. The equipment consists of two Crossley gas producers, specially designed for the gasification of wet peat, and two Crossley gas engines. The peat is obtained from a bog 12 miles distant from Portadown, and after air drying is transported to the works by water carriage. The gas producers are worked on the suction principle, and no attempt is made to recover any byproducts, although scrubbers are employed to remove the tar that has escaped destruction in the producers. The composition of the gas is as follows: H, 18 per cent.; CO, 19 per cent.; CH_4, 1.6 per cent.; CO_2, 7 per cent.; N, 54 per cent. The calorific value of the gas is 140 B.t.u. per cubic foot. During a test run of six hour's duration, made in October, 1911, with a load of 250 hp., the consumption of peat amounted to 2.55 lb. per b.-hp.-hr. From these figures it is calculated that if peat were delivered at the producers at a total cost of $1.20 per ton, power could be generated at this plant with an expenditure for fuel of 0.124c. per b.-hp.-hr.

Some difficulties have been experienced at this Portadown plant with the tar, but by increasing the amount of wash water (used for cleansing the gas by spraying) to 7 gal. per b.-hp.-hr., this trouble has been overcome, and the engines can now be run for three weeks without cleaning the valves.

About 100 tons of peat tar are produced annually at the Portadown works. As no outlet has yet been found for it, the Swedish and German methods of converting it into gas would appear to be more advantageous, especially as, according to Pegg, 5 per cent. of the weight of the raw peat is recovered in this form. Figs. 12 and 13 are views of the producer plant at Portadown.

Gasification with Recovery of the Ammonia

The peat-gas power plants described above are worked without recovery of the ammonia. It is now advantageous to consider whether better economic results could be obtained by adding an ammonium sulphate plant to an installation of producers and gas engines. In a paper read before the Liverpool section of the Society of Chemical Industry, in November, 1916, Professor Baly discussed this question at considerable length, and many of the figures that follow are taken from his paper. As an example of the amount of sulphate of ammonia that can be recovered from peat, the tests made with producers of the Mond type, at the works of the Power Gas Corporation at Stockton-on-Tees, may be quoted:

	German Peat	Italian Peat	English Peat
Moisture content	40 to 60 per cent.	15 per cent.	57.5 per cent.
Nitrogen content	1 per cent.	1.58 per cent.	2.3 per cent.
Gas from one ton of theoretically dry peat	35,000 cu.ft.	60,000 cu.ft.	90,000 cu.ft.
Heat value (B.t.u. per cu.ft.)	150	166	134
$(NH_2)_4 SO_4$ per ton of theoretically dry peat	70 lb.	115 lb.	215 lb.

The German engineers, Frank & Caro, have devoted considerable attention to the problem of adapting the Mond producer to the gasification of peat, and a large installation of this modified type of the Mond gas producer was at work in northwestern Germany on the Schlweger bog before the war. Their method of overcoming the special difficulties caused by the use of peat containing 50 to 70 per cent. of moisture is to increase the temperature of the drying zone of the producer to 250 deg. C. (482 deg. F.). According to Baly, this increase gives an intensive combustion of the coke, an increase in the size and temperature of the combustion zone, and consequently an almost quantitative recovery of the nitrogen as ammonia.

The total amount of steam used should not exceed, however, half the weight of the peat gasified. Baly gives the following figures, as typical of the results obtained with the Mond producer (as modified by Frank & Caro) when working on peat containing 50 to 60 per cent. of moisture. One ton of theoretically dry peat gives from 88,000 to 92,000 cu.ft. of gas. Of this total 39,000 cu.ft. is used in the producers for the air steam blast, leaving 49,000 to 53,000 cu.ft. as surplus. From this surplus gas 700 to 750 hp.-hr. can be developed The recovery of nitrogen as ammonia is from 70 to 85 per cent. of that contained in the fuel, and the yield of tar is from 3 to 6 per cent.

As regards the cost of power, Baly states that the

[1] "Producer Gas Power Plants—Developments in Europe." U. S. Bureau of Mines, Bulletin 4, 1911.

original figure given when the process was first brought before the public was 0.12c. per hp.-hr., but in 1911 figures were published for the Schlweger bog plant that showed that all the expenses were covered by the value of the recovered byproducts. At this date the capacity of the plant was 6000 kw., and each ton of theoretically dry peat produced 1000 hp.-hr. and 90 lb. of ammonium sulphate. Peat containing up to 70 per cent. of water was used in the producers. The tar obtained was distilled to secure paraffin wax and neutral oils.

A peat-gas power plant using a method similar to the modified Mond method of working is also in operation at Codigoro, in Italy. The peat, after preliminary drying and crushing, is charged into a producer 30 ft. high, having the combustion zone near the bottom. The combustion is regulated by a hot air and steam jet, and the plant is said to recover, as ammonium sulphate, three-fourths of the nitrogen in the raw peat, or 170 lb. per ton. The original plant treated 1500 cu.ft. of peat per day, and produced 50 tons of ammonium sulphate per month, with electrical energy equivalent to 800 hp. The plant has recently been enlarged, and according to the latest figures is now treating 17,000 tons of dried peat annually and producing 10 to 12 tons of ammonium sulphate per day.

FIGS. 12 AND 13. VIEWS OF PEAT GAS PRODUCER PLANT AT PORTADOWN, COUNTY ARMAGH, IRELAND

Although powdered peat has not been long before the public as fuel for steam-raising purposes, many engineers, including myself, believe that this method of utilizing this fuel will expand rapidly, and that it will take the place of the older method of briquetting the peat before burning it for power purposes. The advantages claimed for powdered peat are that it is easily produced and that it burns with an intensely hot flame, owing to its high percentage of volatile matter.

The method of producing peat powder varies In Sweden the peat is dug, machined, spread on the bog to dry and cut into bricks, in the manner customary for briquetting. The air-dried bricks contain 50 per cent. of water, and are crushed to a coarse powder in specially built machines. This powder is then dried in rotary dryers. In Canada a novel system of collecting peat powder has been tried, based on the use of pneumatic collecting machines. The cleared and smooth surface of the bog is lightly scored by a harrow, and after a few hours' exposure to wind and sunshine the thin layer of peat powder becomes dried down to 30 per cent., or less, of moisture. This dried dust is then collected by air suction, the collector being operated electrically and mounted on rails.

A collector of this type can gather (on a favorable day) 40 to 50 tons of air-dried peat, at a cost of only $1.44 per ton. After screening, the moisture content, if desired, can be still further reduced by artificial drying.

A further advantage of peat powder as a fuel is that it can be handled and transported more cheaply than briquets, when employed for steam-raising purposes. There is said to be no danger from self-ignition, although this seems doubtful.

The only figures covering the efficiency of peat powder as a fuel are those published by Ekelund, who stated that 1.2 tons of peat powder, containing 15 per cent. of water, was equal in evaporative effect to one ton of the best coal. The cost of producing peat powder in Sweden, in 1911, was given as $2.06 per ton.

In 1913, or just before the war, the Finnish Government made a grant of $48,000 to the Turf Fuel Co. to aid it in erecting a factory for the production of "dust peat" near the railway station at Rychimyaki. This arrangement was based on the experience gained on the Stockholm-Rimbosk Ry., in Sweden, on which line the locomotives since 1911 had been worked with the new form of fuel. The war of course stopped these contemplated developments in Finland, but there will now be a considerable expansion of the powdered-peat industry in Scandinavia, northern Russia, Canada and other countries, where the climatic conditions are favorable.

For large central stations for electric-power generation the production of gas from the partially dried peat in gas producers of the double combustion-zone type and the use of this gas in large gas engines is certainly the most economical and practical method of utilizing the peat.

For steam generation and the heating of large furnaces generally the use of powdered peat offers many advantages over the briquetted form of the fuel, in addition to the greater cheapness of production. Therefore, in those countries where the surface of the bogs and the climatic conditions favor the production of peat powder, developments for producing this form of the fuel in large quantities may be expected to occur.

For domestic heating purposes the machine-made brick or briquet is the cheapest, and I do not believe that the more elaborate processes used to produce a peat coke, or *tourbon*, will be found to pay their working expenses in those districts where peat must be sold in competition with coal.

The author's thanks are due to the Acting Director of the United States Bureau of Mines for permission to reproduce Figs. 7, 9, 10 and 11 from Bulletin 4, published by the U. S. Department of the Interior before the war, giving information and views of various producer gas power plants in Europe.

Convention of National Retail Coal Merchants' Association

Special Correspondence

SYNOPSIS—*The second yearly meeting of the retailers, held at Buffalo, May 14-16, proved most profitable and interesting to those present. Many excellent addresses were given, and a decided effort was made by the leaders to imbue the members with a new feeling that would supplant the old feeling of selfishness. Coöperation was the keynote of the proceedings.*

THE National Retail Coal Merchants' Association held its second annual convention in Buffalo on May 14-16, following the initial one held at Pittsburgh last year. Hon. W. Albert Smoot, of Alexandria, Va., the president of the association, was too ill to attend and his place was taken by John E. Lloyd, of Philadelphia, first vice president. The program was varied and interesting, bringing out men of note in the trade.

Only a morning session was held on the first day, the rest of the day being spent at Niagara Falls, closing with a supper at the Prospect House on the Canadian shore. The chairman of the local committee of entertainment, Albert H. Tracy, Jr., was suddenly taken severely ill and the arrangements were taken up by J. W. Noble.

The chair spoke briefly on coöperation and said that it was bound to take the place of the old selfishness in trade, which had worked a great deal of harm for a long time. It would be a splendid thing if the coal dealer, handling as he does one of the vital necessities of the world, could take the lead in this movement.

John M. Daly, of London, Ont., vice president of the Canadian Retail Coal Association, spoke as the "mouthpiece of the trade across the border." He said that the American fuel administration had been of wonderful help to Canada during the coal shortage, in spite of the fact that the dealers disliked to make reports of their sales, for it put them on an equal basis with the consumers in the United States. He complained only of the shortage, and said the mines should be made responsible for weights. He referred feelingly to the great sacrifice that Canada had made in the war. It was as great in personal losses as those of the United States, though the population was only equal to that of New York State.

The credentials committee found only about half of the affiliated associations represented, but further reports finally placed most of the 25 in line.

The nominating committee presented the names of 21 delegates as suggestions for directors. They were later elected without change, and are as follows: For three years—W. A. Smoot, Alexandria, Va.; Charles B. Staats, Albany, N. Y.; Walker Cottrell, Richmond, Va.; Wellington M. Bertolet, Reading, Penn.; Samuel Munter, Indianapolis, Ind.; John M. Daly, London, Ont.; A. P. Smith, Denver, Col. For two years—John E. Lloyd, Philadelphia, Penn.; W. A. Clark, Boston, Mass.; W. Hamilton Smith, Washington, D. C.; James C. Tattersall, Trenton, N. J.; Wallace G. Phinney, Boston, Mass.; Thomas Cossey, Danville, Ill.; William Bartrim, Kansas City, Mo. For one year—B. M. Watts, Baltimore, Md.; W. T. C. Berlin, Memphis, Tenn.; Milton E. Robinson, Chicago, Ill.; Albert E. May, Rochester, N. Y.; Richard J. Wulff, Brooklyn, N. Y.; Edward Schiewe, Detroit, Mich.; Arch. Coleman, Minneapolis, Minn.

"Wholesale and Retail Relations" was taken up at the Thursday morning's session by Arthur E. Rice, commissioner of the Coal Merchants' Association of New York. He said that the three branches of the trade should be brought together, instead of each trying to do business at the expense of the others. The organizing of the national association was a long step toward the accomplishment of this result. Much had been done by the Pittsburgh convention of that body. What constitutes a retail dealer should be sharply defined, and no other should be allowed to distribute coal. As to car weights, the wholesaler should be responsible for that, and he should give up that responsibility only on delivery. The operators who send out impurities in coal were reminded that the consumer is buying substitute fuel in quantity, and that crude oil is supplanting coal in a great many localities. The speaker was sure that many difficulties had been brushed aside so that the three branches of the trade could be brought together and much good accomplished.

Defines Function of Retail Dealer

Committee reports followed, and J. C. Tattersall, of Trenton, N. J., on invitation from the chair, told of the card system in use by his local association. By it the dealer could refer to every sale made in the city and note the price paid. Consumers were not allowed to get more than six months in arrears.

George H. Cushing, managing director of the American Wholesale Coal Association, spoke in the afternoon on "The Function of the Retail Dealer." After defining "function," he said the retailer's duty was to buy coal in car lots and sell it in less than car lots; to sell when it was wanted, and to furnish what was wanted. He said the retailer was a merchant, a warehouseman, a cartman and a banker, and should know what each of these branches contributed to his business as a whole. Sometimes one produced a profit while another did not. Speaking of the retailer's many bosses—those he bought of and those he sold to—he was sure that an effort to reform them would be difficult, so that it would be easier for the retailer to reform himself. No retailer really owned his business. He owned only the machinery of it. Mr. Cushing closed by referring to the establishment of a system of banks that were prepared to relieve merchants of doing any part of their own banking, by giving credit to buyers direct.

The address on "Coöperation in the Coal Trade," by E. W. Parker, director of the Anthracite Bureau of Information, wound up the regular program of the day. Mr. Parker said that the advance in the price of anthracite since 1913 was only 51.5 per cent., while nearly

everything else had advanced much more. Milk, which was the highest on his list, had advanced 163 per cent. One reason, the speaker thought, for more complaint of the high price of coal than of most other things, was that it was sold by the ton, while other commodities sold by the pound or dozen. Proceeding to show the mining cost of anthracite coal, he asserted that one advance of 35c. a ton was all that the Government would allow against an advance of 45c. to the miners.

The convention took up the subject of advertising and an enthusiastic indorsement of it was the result. Many reports of success were made. A general and continuous use of the daily papers, for the purpose of keeping the public informed on the state of the coal trade, was advocated by every speaker.

The regular banquet of Thursday, given in the convention hall, was largely attended. Enjoyment of the informal kind, with music and dancing, took the place of set speaking.

The Friday session was confined to the forenoon, as some of the speakers on the program did not appear. Peter Beck, of Harvey, Ill., read a short paper on "Sales to Employees," in which he argued against the practice. He was aware that it was an effort to keep the men more satisfied and prevent strikes. All selling of coal or anything else below what it should bring was demoralizing to the trade and did nobody any good in the end.

The customary resolutions, thanking the local trade for the fine entertainment it had given the visitors, were adopted. It was also found proper to remember the members of the association who were ill, of whom there was an unusual number. The resolution asking the operators to reduce the sizes of anthracite brought forth an animated general discussion. All agreed that there were too many sizes, but some took the view that the convention as a whole was not called on to discuss the matter. A resolution to refer the matter to the executive committee was lost. The plan was to call lump and large pea extra sizes, and to include two between them. Of steam sizes it was held that three were enough. In this form the resolution was adopted. The convention put itself on record as opposed to the gross ton.

The directors announced the election of the following officers: President, John E. Lloyd, Philadelphia; first vice-president, Peter Beck, Harvey, Ill.; other vice presidents, W. A. Clark, Boston; T. Percy Bryan, Kansas City, Mo.; W. Hamilton Smith, Washington, D. C.; Charles D. Staats, Albany, N. Y.; H. D. Jones, Chicago; treasurer, Samuel D. Crowell, Philadelphia.

The officers, with the following appointed by the president, make up the executive committee: W. A. Smoot Alexandria, Va.; R. R. Yeagley, Indianapolis; W. T. C. Berlin, Memphis, Tenn.; W. M. Bertolet, Reading, Penn.; W. B. Phinney, Boston; A. F. Rice, New York; J. Harry West, Baltimore; Walker Cottrell, Richmond, Virginia.

The final address was given by Stanley B. Houck, who had come from Minneapolis to be present the last day. He began by referring to the bolshevists and socialists as being always posted on their beliefs and principles and ready to fight for them. The coal association should take a lesson from them, and the members should not only know what they wanted, but be ready to take off their coats and defend it. When they went to Washington to ask for anything, they should know what they wanted and work together. He has known cases to come up before the Interstate Commerce Commission when nothing was accomplished because the petitioners, though all wanting the same thing, could not agree to present their views as a unit.

A point of vital interest to the convention was presented by W. L. Noble, of Buffalo. He had gone with a delegation to the Larkin plant to inquire into the report that the company was selling coal to its employees at cost. This was denied by John D. Larkin, Jr., but with the admission that it was being sold at a reduction of $1 to $1.25 below the local price by a coöperative association of the employees. The delegation tried to get Mr. Larkin to stop the practice or to oppose it in some way, but failed. Mr. Noble said that he did not think enough coal would be sold in this way to hurt anybody's trade, but the moral effect was bad; for if one sold in that way others would. He promised to watch developments and report.

At 1 o'clock the convention came to the end of its program, having completed an interesting and profitable meeting. The convention adjourned with a rising vote of appreciation of the work of the president, John E. Lloyd.

Kentucky Mining Institute Meeting

The annual meeting of the Kentucky Mining Institute will be held at the Phoenix Hotel, Lexington, Ky., June 6 and 7. President Meguire will open the meeting on Friday, June 6, at 1:00 p.m., after which the following papers will be read: "Zinc and Lead in the Kentucky-Illinois Fluorspar District," by A. H. Reed; "Human Engineering," by M. L. Fellmer; "Gas and Coal Dust in Mines," by Col. A. G. Burrell; "Chemistry of Coal," by Major A. C. Fieldner; "Schedule Rating of Coal Mines for Workmen's Compensation," by H. M. Wilson; "Safe and Dangerous Practices in Coal Mines," by D. J. Parker. At 8:00 p.m., after the luncheon, the following papers will be read and discussed: "Depreciation and Depletion," by C. D. Burdick, and "Has the Metal Industry Any Lessons for the Coal Industry?" by R. Dawson Hall.

On Saturday morning, at 9:00 o'clock, Frank Morris will read a paper entitled "The Activities of the National Safety Council," followed by "Storage Battery Locomotives in Mine Work," by J. Appleton; "Mine Rail Bonds," by C. C. Beck; and "Permissible Explosives," by J. E. Miller. In the afternoon, at 2:00, a first-aid contest will be held for the "Institute Placque," won in 1917 by the team of the Stearns Coal and Lumber Co. The contest will be conducted under the regulations of the American Red Cross. Teams desiring to compete are asked to file the names and addresses of the team members, and the company they represent, with C. W. Strickland, Box 910, Huntington, W. Va., not later than June 2.

Referred to the Anti-vivisectionists

A cruel use of men to safeguard the lives of canaries and mice has been discovered by Emery R. Hayhurst, consultant in industrial hygiene, Ohio State Department of Health. In a recent report published in *The Ohio Public Health Journal*, February, 1919, p. 67, he says: Afterdamp "has rather more effect on canaries or mice than upon men, so that the latter have been used as test animals."

Dirt in Coal*

THE ash content in coal varies widely in different localities and frequently there is considerable variation in the same locality under different conditions of mining and preparation. The normal amount of ash may be considered as that found in the face sample of the seam proper; the excess ash is that which is added from the roof or bottom in the process of mining and which is not eliminated before the coal leaves the mine.

Lump coal made over a 1¼ in. screen usually shows the normal per cent. of ash, while the 1¼ in. screenings in most cases show one and one-half times the percentage of ash contained in the lump. This is due to various causes. Where mining machines are used they occasionally drive the cutter bar into the fireclay bottom, either by a failure to properly set the machine, which is gross neglect on the part of the machine operator, or through the cutter bar striking an uneven area of bottom clay under the coal seam, which is unavoidable.

Another factor enters here: The bottom bench of a coal bed frequently contains a greater proportion of ash than the upper benches, and undercutting in this bottom bench is one cause of increasing ash in the screenings. These undercuttings from a 6-ft. seam amount to about 7 per cent. of the output. Where the coal bed lies under a shale covering or roof, it frequently occurs that a portion of this cover comes down and mixes with the coal, as a result of heavy blasting and scaling off due to air striking it. This shaley substance easily slacks and finds its way into the screenings.

The ash content in screenings can be reduced nearly to that of the screened lump by the use of a jig gravity washer, with an ample water supply and a convenient place to deposit the refuse. However, the washing of screenings has been considered too expensive while the price of all coal was low, but since prices have gone 60 per cent. and more upward, and will probably remain so, it may be well, and at the same time profitable, to eliminate the excess ash by washing in the vicinity of the mines, thereby saving the use of cars for and the long haul on inert material amounting to about six mills per ton-mile to points where coal is finally consumed.

The following table showing ash and B.t.u. content of coal from a bituminous mine in the Central West district illustrates how the ash content of screenings can be reduced by washing:

	Ash	B.t.u.
Dry or unwashed screenings	22.61%	8,895
Washed screenings	14.05%	10,085
Lump	12.39%	10,499

The excess ash in mine run and prepared sizes, made over a 1¼ in. screen, consists chiefly of blue band, sulphur band, sulphur boulders, or lenses from the vein; and from the roof, slate, shale and rock which frequently comes down with the coal as a result of improper blasting or lack of proper timber. This foreign matter can easily be removed by hand by the miner at the working face when loading into mine cars, or by having men or boys working on picking tables or belts while the coal is passing to the railroad car.

The performance of this work can be supervised by regularly assigned fuel inspector. He often finds the mine manager or superintendent letting his miners become lax in cleaning coal at the face and using too much powder for blasting, or the dock boss and slate pickers on the tipple becoming dilatory in their work, the result being increased ash. A protest to the proper mine official by the inspector usually brings about a correction; again in other cases rejection of the coal will bring about results.

The Illinois Central R.R. is using a system of close inspection with suggestions to the mine superintendents on the ground while the coal is being loaded. As a result of this effort, the impurities removable by hand picking and based on actual carload tests have been reduced from an average of 2.733 per cent. in the year 1911 to an average of 1.535 per cent. in the year 1917, or a net reduction of 1.198 per cent., which applied to a consumption of 4,000,000 tons of coal used annually represents 47,920 tons less ash, requiring the use of 958 fifty-ton cars to move. The transportation cost of moving this excess ash an average distance of 266 miles, based on an "out of pocket" cost of five mills per net ton-mile, equals $63,733.60 per annum. This, however, is but a lesser saving.

Taking the established estimate of increase in efficiency due to reduction in ash of 1½ per cent. for each reduction of 1 per cent., the saving from this source—that is, the increased evaporative efficiency—with coal at a delivered price of $3.68 per ton equals $264,518.40, or a total saving of $328,252 per annum. What the measure of the economies following from reduced engine failures and reduction in engine-house expense amounts to is difficult of computation.

Waste Due to High Ash in Coal

The total bituminous coal mined in the United States last year in round numbers approximates 585,883,000 tons, of which the railroads of this country consumed about 30 per cent., or 175,764,900 tons. Now assuming that if 1.198 per cent. of the excess dirt or ash had been removed at the mines, it would have reflected a saving of 42,193 cars, and the consequent expensive burden entailed by transporting and handling this "fuel parasite" through the regular channels to the refuse piles at some terminal points.

The Bureau of Mines has received repeated cases of complaint from coal consumers generally during the past year wherein the ash content in coal that normally runs 6 to 8 per cent. has increased to 12 and as high as 18 per cent.; now, if we assume 5 per cent. to be a fair average of the increase in ash, it would mean 585,883 carloads of burden to be handled on the entire output for last year.

The higher per cent. of impurities, especially sulphur in the form of iron pyrites, in coals running high in volatile matter, is a dangerous element in storing mine run or screenings, as these coals often ignite spontaneously when sufficient moisture is available to cause oxidation of the sulphur. This causes a rise of temperature sufficient to ignite the smaller particles of coal, which when properly mixed will start the whole pile burning. However, I have never experienced this effect where screened lump coal, free of all slack, was stored.

*Paper presented before the International Railway Fuel Association by L. J. Joffray, general fuel inspector for the Illinois Central Railroad.

The effective combustion of coal depends largely on the nature and per cent. of impurities it contains, especially so if the ash has a tendency to clinker, which is dependent on the percentage of silica, iron and lime in its composition. Tables I and II give analyses of coal and ash used in ten burning tests from ten different mines in Illinois and Indiana.

Table I gives the usual proximate analyses of the coals. Table II gives analyses of the ash. By referring to the column showing the clinkering and non-clinkering coals and then making a review of the ash table, we

TABLE I. ANALYSES OF COALS

Test Number	Moisture, Per Cent.	Volatile Matter, Per Cent.	Fixed Carbon, Per Cent.	Ash, Per Cent.	Sulphur, Per Cent.	B.t.u.	Clinker
1	3.37	31.31	55.19	9.63	0.64	12,325	No
2	6.02	30.00	53.50	10.30	1.30	12,136	No
3	4.61	31.35	54.05	10.00	1.19	12,368	No
4	2.92	33.10	51.25	12.73	2.96	12,389	Yes
5	4.99	39.22	43.99	11.80	4.43	11,768	Slightly
6	3.41	37.12	45.62	13.85	4.02	11,842	Yes
7	5.13	37.70	44.31	12.80	4.52	11,693	Yes
8	2.86	36.04	43.14	17.96	4.58	11,124	Yes
9	8.49	34.87	48.16	8.48	1.47	12,251	No
10	4.68	38.59	44.24	12.49	4.50	11,921	Yes

observe that the coals with non-clinkering ash are low in both sulphur and lime. In burning they did not clinker in a dazzling white fire of an approximate temperature of 2900 deg. F., while the ash in the clinkering coals fused at a firebox temperature of approximately 2200 deg. F. This indicates clearly that when the sulphur and lime content exist in high proportion to the silica, iron and aluminum oxides, it is the direct cause of the ash fusing at the lower temperature.

The bottom line of Table II shows the fusing point of the sulphur and the different oxides. From this it will be seen that by taking each element separately the fusing point is at a higher temperature than is usually obtained in the furnace of a boiler. However, by combining these elements in proper proportion with the sulphur, fusion at a much lower temperature take place.

The conditions of these ten experiments as to draft, etc., were identical in each case. However, I have since

TABLE II. ANALYSES OF ASH

Test Number	Sulphur (S) Per Cent.	Silica Oxide (SiO_2), Per Cent.	Iron Oxide (Fe_2O_3), Per Cent.	Aluminum Oxide (Al_2O_3), Per Cent.	Calcium Oxide (Lime), (CaO) Per Cent.	Magnesium Oxide (MgO), Per Cent.	Color of Ash
1	0.64	59.0	3.1	31.0	5.6	1.3	White
2	1.30	55.2	8.3	26.6	7.3	1.3	White
3	1.19	56.1	8.1	27.2	5.4	0.9	Light Gray
4	2.96	45.4	25.3	16.9	11.6	0.8	Reddish Gray
5	4.43	49.1	32.2	13.5	4.5	1.4	Reddish Gray
6	4.02	35.1	22.4	10.2	30.8	1.5	Reddish Gray
7	4.52	43.3	24.1	9.0	19.9	1.2	Reddish Gray

Fusing Tem.°	239	3227	2840	3416	3452	3882	

observed that either one of the coals containing the clinkering ash will give better results both as to combustion and reduction of slag in the ash by increasing the draft, which increases the flow of air through the fire bed and has a tendency to keep the temperature of the fire below the fusing point of the ash. Hence it is always good policy to assign the clinkering coals to a lower class of service, such as switch engine, local freight, and other light runs. However, when considering the possibility of burning the low grade clinkering coals to profitable advantage, such should not be construed so as to minimize the responsibility of those who are assigned the duty of eliminating all impurities.

Mine Owner Held Not Liable for Injuries From Dynamite

In the case of Richards vs. Fleming Coal Co., decided by the supreme court of Kansas on Mar. 8, the mine operator is held not liable for injuries to a shotfirer from an accidental explosion of a charge of dynamite, the reason being that the servant at the time of the injury was violating the law concerning the use of the explosive in coal mines.

A law of Kansas (1909 Ch. 175) makes it an offense for anyone to use dynamite in a coal mine except under such rules as may be agreed upon between the employer and employees, with the approval of the state mine inspector. It appeared that the dynamite was generally used at the mine in question by exploding it by means of a plunger electric battery, and that such a battery could not explode the charge accidentally. The plunger battery got out of order and the servant was directed to use a dry cell. While arranging the wires and carrying a small charge of dynamite, the wires came in contact with the dry cell and caused an explosion.

The court denied the contention that the law was unconstitutional on the ground that it delegated power to the operators and miners to make rules which might vary with different localities. It was also held that the statute applied to a strip-pit mine as well as to one with underground workings.

The Storage Battery Returns to Peace

Announcement has been made by the Electric Storage Battery Co. that the United States Government has given it a release on the "Ironclad-Exide" storage battery and that this product is now ready to take its accustomed place in those phases of industrial life where a storage battery of this character is an important factor.

Some items of the paraphernalia of modern warfare are not generally listed in the histories. For instance, the storage battery is used in battleships to furnish auxiliary power, not only for the intricate system of inter-telephone communication which keeps every department in touch with every other department, and for the lighting of cabins and gun decks, but for the actual operation and firing of the guns themselves. It also stood as a reserve behind the powerful searchlights with which the submarine chasers were equipped. Electrical accumulators, also, provided the power for undersea operation of Uncle Sam's submarines.

In almost every field of war activity storage batteries had their important corner. They were used on airplanes to provide ignition and starting power, and for the operation of the important landing lights. They furnished the vitality for the field wireless; put the punch into the starting and lighting of officers' automobiles; operated the electric locomotives and electric industrial trucks used in munition plants and on loading platforms; provided auxiliary power for the raising and sighting of our big coast defense guns, as well as that behind the operation of the lighting and telephone system of fort, army post and cantonment.

It is one of the strongest proofs that the world is again right to see our boys coming home; it is no less a cheering sign to see many units of the machine of war disassembled and taking up their old work.

What Price Should the Coal Operator Charge the Boiler-Room Coal Account?

By C. W. Hippard
Urbana, Ill.

SYNOPSIS—*A few years ago many operators knew little about the details of the cost of coal production and preparation at their plant. The Federal Government monthly expense reports have tended to change all this. With the distribution of coal-production expenses, much information was gained. The following article takes up one phase of mine operation—the boiler-room coal. It is worthy of discussion, as it is an important item in the running expenses of a mine.*

PROMINENCE was given to the subject of the cost of coal production and preparation by the requirement of the Federal Government of a monthly expense report from all coal operators. Furthermore, in this day of scientific management, a cost-accounting system is an essential part of every up-to-date business. There has been considerable discussion about many of the details of colliery cost accounting in which was included the price the coal operator should charge the boiler-room coal account. There are several ways of solving this problem; either by charging the boiler-room account with the coal used at some definite price per ton, or by ignoring it altogether.

Formerly, it was common practice to take no account of fuel burned under boilers at the mine. It is not always easy to arrive at the exact price per ton which should be charged for this fuel; it may be an inferior grade of coal, which is not marketable. Furthermore, the weight of coal thus used is rarely known unless a special effort is made to ascertain the facts in the case. However, boiler-room fuel is an actual expense and should be charged. A company should know just what operating expenses to charge up to each department; if the costs are too high, the situation should be carefully investigated to see where costs can be reduced. There are a number of ways of arriving at the price which should be charged for boiler-room coal, and the various methods are all open to discussion; for the purpose of comparison, each is here given and commented upon.

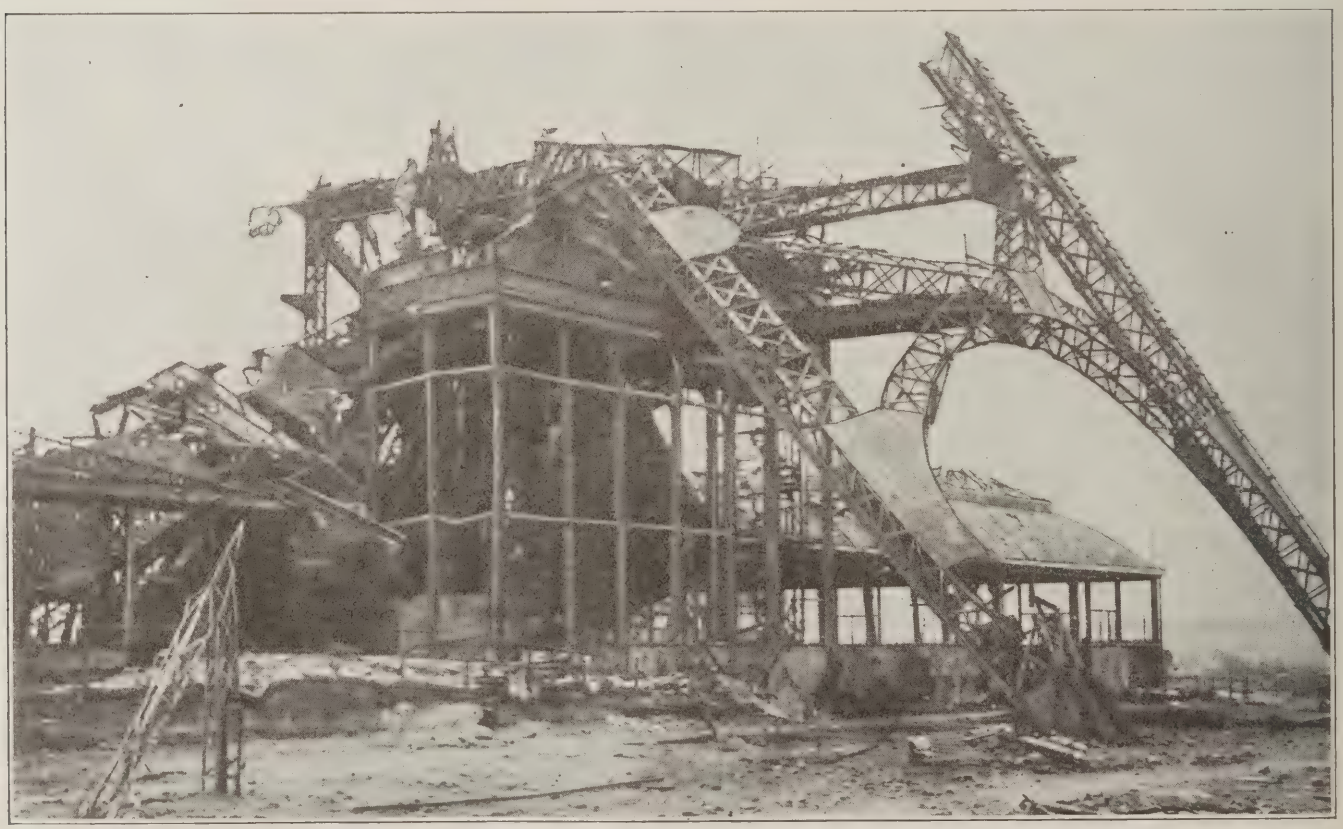
First, considering the cost-of-mining price method. The plan of adopting the cost of mining as the price per ton to charge for coal appears logical. Some charge the actual cost of mining the coal, while others include overhead. The method of charging the actual cost of the coal has the advantage that it does not permit of a profit on coal used at the mine to appear on the boiler-house account. The disadvantages are that the cost of mining varies from day to day and discrepancies are introduced when a fixed price is used. Then, as is often the case, a grade of coal may be used which is sold in the market for a price which is less than the cost per ton of mining the entire output. Thus, when screenings are used under the boilers at the mine, the mining price should not be charged, as screenings sell for an amount less than the cost per ton for mining the entire output. On the other hand, the coal used in the colliery boiler room lessens by just that amount the tonnage which might be sold at a profit in the market, so the coal used in this way might be viewed in the light of a loss. This has led some people to believe that coal used at the mine should be charged at the market price.

This brings us to the second, or the market-price, method. This has the appearance of being a logical method, but fundamentally it is not. Thus, when there is a shortage of railroad cars for transportation, should all the coal produced at the mine be considered as having a value equal to the market price? The only coal for which a market price can be obtained is the amount which can be shipped to market. On the other hand, when there is a big car supply, the coal used at the mine should be worth the market price; for if it were not needed at the mine, it could be shipped to market. At all events the market price is variable, and a variable cost for mine boiler coal should be avoided if possible.

Third, let us consider the local trade price. Some operators consider that boiler-room coal should be charged at the same price as coal sold in wagon lots at the mine to local trade. Probably the only advantage of this method is that the price is likely to be fairly constant.

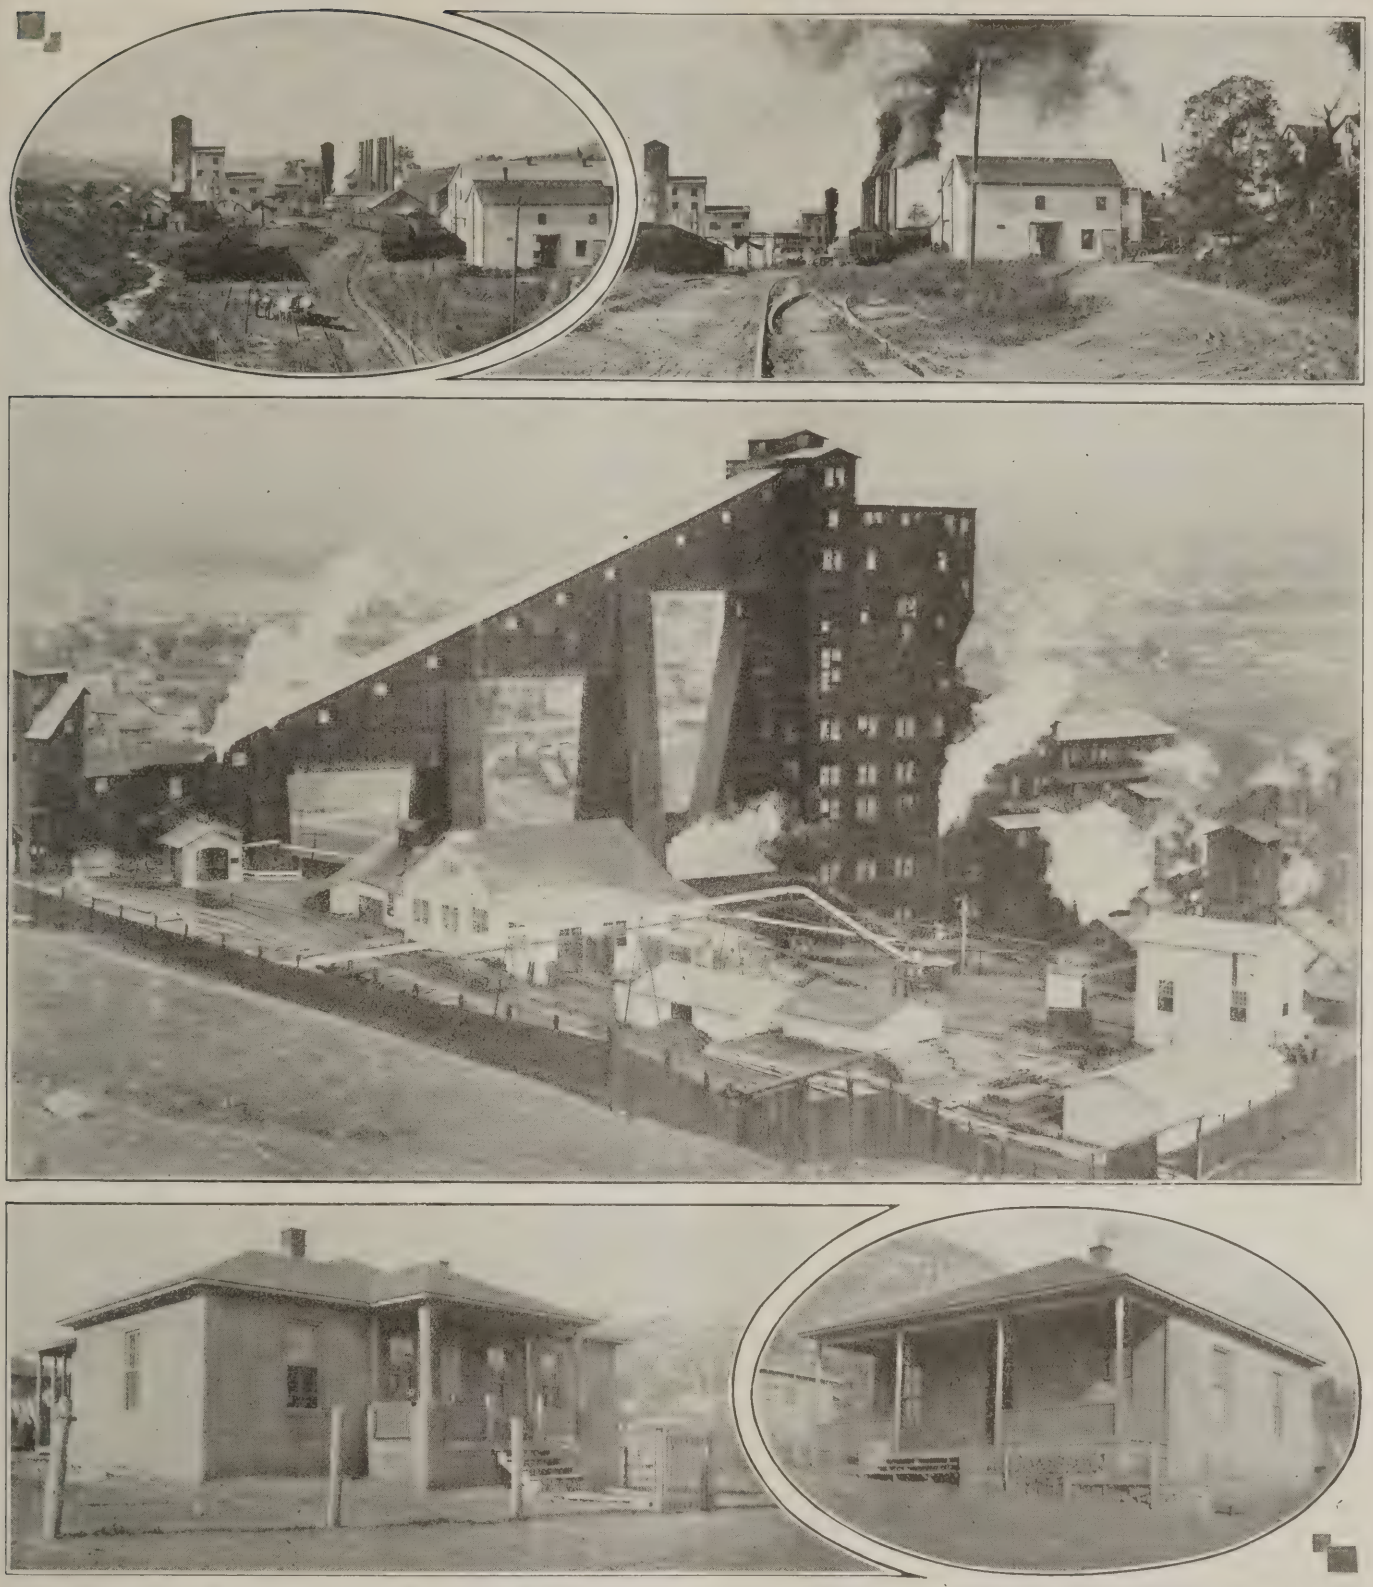
A fourth method includes a price compared with purchased power. The price of boiler-room coal may be calculated on the basis of comparison with power which may be purchased at a mine from an independent power company. This method is not generally adopted in accounting, as far as known. But at least one operator has been heard of who took a bid of a power company to supply power, and compared the offer of the power company with the amount he had been paying for the power generated in his own plant. Thereafter the operator considered the furnishing of coal to his boiler room as a contract at a definite price.

In reviewing all the methods considered, my conclusion is that the best plan is to ignore the cost of boiler-room coal in the cost accounting. Such items as waste of coal at the mine, discarding of impurities, difference between mine and railroad weights, among others, should be taken care of automatically. One advantage of keeping separate records of the items just noted might be the effect such a system would have on the management; any loss traced directly to some cause would tend to be remedied, or at least reduced to a minimum. Some of the comments here made do not agree with theoretical accounting practice, and I would welcome a discussion of the various methods by the readers of *Coal Age*.



An authority on boiler practice has stated that in addition to the necessary and usual pressure gages and draft gages on boilers, it is also necessary to have a steam flow meter for the purpose of showing the amount of steam being delivered by each individual boiler. Steam flow meters indicate at once those boilers which are not up to the average. With this information changes can be made in drafting fires, to equalize conditions.

SNAPSHOTS IN COAL MINING



CUTTING PEAT IN A BOG IN SOMERSET, ENGLAND

It has been pointed out by experts both in America and in Great Britain that a mixture of peat and coke forms an ideal fuel for kitchen use. In England peat is used almost entirely in the districts where the bogs are found, and a new bill recently introduced in Parliament would facilitate the cutting and distribution of peat in greater quantities.

WHAT THE GERMANS LEFT OF THE COAL MINES OF LENS

As the British drove the Germans from the industrial centers in the north of France the latter wantonly destroyed every manufacturing plant. The coal mines, however, appear to have met with particular vengeance, for these were demolished completely. The photograph was taken in the autumn of 1918 and affords an idea of what the structures in the Lens region now look like.

TOP—VIEWS OF THE MANIFOLD MINE OF THE YOUGHIOGHENY & OHIO COAL CO., MANIFOLD, PENN.
CENTER—SURFACE PLANT AT THE FORTY FORT COLLIERY OF THE TEMPLE IRON CO., FORTY FORT, PENN.
BOTTOM—COMPANY HOUSES OF THE STAG CANON FUEL CO. AT DAWSON, N. M.; HOUSES OF THE TYPE SHOWN RENT FOR $2 PER ROOM PER MONTH

WILL PAY $5 FOR THE BEST MINE PHOTOGRAPH

A READER can oftentimes obtain more information from a rapid glance at an illustration than from a laborious reading of paragraph after paragraph of mere descriptive matter. The illustrations accompanying the write-up of a new mine plant for instance, help to convey the story. Used in conjunction with a well prepared article, illustrations are an invaluable aid to proper understanding. All this is by way of preamble to a confession. *Coal Age* is meeting with ever-increasing difficulty in procuring photographs that will be of general interest and technical value to colliery men. So we want to enlist the aid of every reader of this paper in this matter. To stimulate interest, the editor of *Coal Age* will pay $5 each week for the best photograph sent in by any subscriber. Prints submitted must be for the exclusive use of *Coal Age* and must not have been previously published. All photographs not awarded the $5, but accepted for publication, will be paid for at a liberal space rate. The sender's name and address, with a brief description of the picture, must accompany each photograph. All prints will be returned, if desired.

Would Divorce Railroads from Ownership in Coal Properties

Before the railroads are turned back to their owners, the American Wholesale Coal Association is urging the members of the congressional committees interested to include in the new statute a provision that the railroads are to be returned to private owners only when they have freed themselves from any control of coal property; any interest in coal lands or coal mines; any connection with banking houses or syndicates which hold coal lands or which own coal mines in the interest of any railroad corporation. "We believe," says the letter to the congressional committees, "that before coal can be put in that position of independence which will allow it to adopt effective means of reform, there must be a complete divorcement of the coal industry and the carriers. We believe the time to make this divorcement complete is when the railroads are returned to private control. We ask you to take this suggestion into account when framing the new laws regulative of the carriers."

Little Hope for Export of Large Volume of American Coal

The allocation of ships in July for the exporting of coal will be too late to be of real service in the present coal situation is the opinion expressed by representatives of operators in Washington. If ships could be supplied immediately, a large tonnage of coal could be moved out of the country, to the advantage of all concerned. The foreign trade committee of the National Coal Association is now negotiating with the Shipping Board in connection with the entire export program.

Due to the inability of operators to work their mines to more than 65 per cent. of full-time capacity, many are of the opinion that there will be little high-grade coal available for export. The shortage of labor, as well as its general inefficiency at this time, has so reduced production that it is believed domestic contracts will take practically all of the output. If it were announced today that even a few ships were to be allocated for coal exports, it is believed that a scramble for contracts would begin at once on the part of coal users.

Operators who are interested in the export trade lament the fact that the negotiations are still in a conversational stage. It is pointed out that operators took up the export matter before the ink was dry on the armistice, but that they were estopped absolutely from carrying out any plan by the official statement that ships would not be available for an indefinite period. Officials now, however, are taking a different attitude and are anxious to start the coal movement. They now find that coal operators, in the face of an almost certain demand at home for their entire output, are more inclined to be deliberate and certain of their ground before taking action. The uncertainty as to the labor situation at the expiration of the Washington wage agreement is another factor having an important bearing on the situation. It is regarded as practically certain that a situation will develop which will militate further against production.

Owing to the prospects of increased demand, the operators were not greatly disappointed when the stabilization program of the Industrial Board failed to materialize. As matters stand at present, the coal industry, it is held, needs no stabilization.

"Tuckahoe" Completes First Year of Service

On May 15, the steel cargo carrier, "Tuckahoe," completed its first year. The "Tuckahoe" has had an eventful career in the coal-carrying trade. She had the distinction of having been launched 27 days after the laying of her keel. While she was diverted to transatlantic use during a portion of the year, most of the time was spent in carrying coal. She now is en route from Norfolk to Rio de Janeiro with such a cargo.

The "Tuckahoe," which is a vessel of 3667 gross tons, broke all monthly records in the coal-carrying trade the first month in service with a total of four cargoes of coal from Norfolk and Baltimore-Boston, 19,000 tons in all. The fastest round trip during the war in this trade was made by the "Tuckahoe" in seven days as against the average time of 14½ days. Her slowest round trip was 12 days. This was due to a change of crew in Boston, delaying her four days in port.

Would Have Engineers Receive Broader Business Training

Encouraged by the nation-wide interest in the movement to incorporate in all engineering courses a greater amount of business training, the Bureau of Education has called a general conference on the subject to be held in Washington June 23 and 24. It is expected that representatives of every technical school in the country will be in attendance, as well as many others who are interested in the subject. The sessions will revolve around these major topics: (1) Business training for the engineer; (2) engineering training for commercial enterprises; (3) significance of the war experience for engineering education; (4) training of the engineer for oversees engineering projects.

Curricula suggestions will be submitted to the conference as follows:

First, that a minimum number of hours in business training, to be determined by the committee, be required in all engineering courses. In respect to this suggestion it was recommended at the Washington committee conference that from 12 to 18 semester hours be required in all engineering courses on the following subjects: General economics; cost accounting; business organization; business law.

Second, that a curriculum providing for a minimum of 15 to 30 units in business economics be incorporated in all engineering courses and offered on an elective basis. In respect to this suggestion the Washington committee conference recommended that electives be encouraged in connection with all engineering courses in the following subjects: Labor and employment problems; statistics; corporation management and finance; political science; marketing, including advertising and salesmanship; psychology; scientific management; transportation. It was further recommended that economic phases of engineering subjects be emphasized wherever possible in engineering instruction.

Third, that a curriculum in commercial or industrial engineering, permitting full and proper emphasis upon engineering subjects, be offered in the School of Commerce, with degree to be given in that school.

Fourth, that a five-year combined engineering and commercial course be prepared. It was recommended at the Washington committee conference that no action be taken at this time on curricula suggestions Third and Fourth.

Consumption of Army Coal in 1918

Much attention is being paid in Washington to the report, now being released chapter by chapter, of the Assistant Secretary of War, Benedict Crowell, reviewing the main activities of the War Department during the period of hostilities. He refers to coal as follows:

During the months of hostilities the American public was constantly informed in advertising literature that fuel would win the war, and indeed fuel would win it, and did win it, in the sense that without fuel or with any grave shortage of fuel we could not have won. In this sense there was no more important commodity contributing to success in the great drama than coal.

America began keeping the records of coal mining in the year 1807. Woodrow Wilson was inaugurated President of the United States in 1913. In the 106 years between 1807 and 1913, and including those years, American mines produced a total of 9,844,159,937 tons of coal. In the succeeding five years of President Wilson's administration American mines turned out 2,960,938,597 tons of coal, almost one-third as much as was mined in the entire 1807-1913 period, and almost one-fourth of all the coal mined in the United States since records have been kept.

The American coal miners in 1918 met the war emergency by producing 150,000,000 tons of coal more than they had dug in 1914. The shortage of coal in the winter of 1917-18 was due not to the inability of the mines to produce the required tonnage but to inadequate railroad transportation facilities and severe weather.

The war-coal project was in the hands of the United States Fuel Administration, but the office of the Quartermaster General assisted in the effort. Army officers were stationed at the offices of the various district representatives of the Fuel Administration throughout the country. These officers kept in constant touch with the factories making war supplies and saw to it that coal was diverted from less essential enterprises to the munitions factories. This service operated with such excellent effect that very few manufacturers working on Government contracts were compelled to suspend operations because of the lack of fuel, and those who did have to suspend were able to resume again within a few days.

During the summer of 1918 the usual seasonal slack in the demand for fuel was taken up by the action of the fuel branch in absorbing practically all of the excess coal in the United States and storing it at Army posts, camps, and stations. This action kept the mines working at maximum capacity during a period when there is normally a curtailment in output. Of course, at the time there was no realization that the fighting was to end so soon, and this policy was adopted in preparation for unchecked industrial activity during the winter of 1918-19.

The Army itself was a heavy user of fuel, requiring it not only at its various manufacturing establishments but also at the great camps for heating purposes. The following table shows the Army purchases of fuel for the calendar year 1918:

	Amount	Cost
Anthracite coal (tons)	710,304	$4,362,237
Bituminous coal (tons)	2,706,737	11,711,335
Total	3,417,041	16,073,572
Coke (tons)	9,576	80,643
Wood (cords)	786,177	5,178,161
Total fuel	.....	$21,332,376

This is a complete statement of the fuel purchases for the calendar year 1918, and includes all Army camps, posts, hospitals and stations in the United States. The fuel branch maintained the policy of keeping on hand at the camps a three months' supply of coal as insurance against possible shortages in the market.

Coal in Northeastern Utah

Coal was found in northeastern Utah on Lost Creek near Devils Slide many years ago, but it has been mined only because fuel is scarce in that region. Reports received from different sources have indicated that the beds discovered may be a part of a good coal field, so the United States Geological Survey sent one of its members to examine the region. The examination proved that the coal along Lost Creek occurs in thin, irregular beds, which are separated into several benches by bone and shale partings, and that it is subbituminous and cannot compete with the coal of higher rank which is found in vast deposits in other parts of Utah and in Wyoming, although it is of considerable value to the residents of small towns and ranches nearby.

The Lost Creek coal field is in Morgan County, Utah, 12 miles northeast of Devils Slide, on the main line of the Union Pacific R.R. For many years small quantities of coal have been mined and hauled by wagon to Croydon, a small town 9 miles southwest of the field, and to ranches on Lost Creek. The coal burns well in stoves and open fireplaces, but contains a high percentage of ash and "slate." It carries so much moisture that it rapidly falls to pieces on exposure to the air.

Geologists describe the coal-bearing rocks as belonging to the Wasatch formation, a Tertiary deposit laid down on the upturned and eroded edges of much older (Jurassic) beds. The Wasatch is composed of three parts—an upper and a lower conglomerate and an intervening series of beds of sandstone and shale. The coal was deposited on the surface of the lower conglomerate.

A copy of Bulletin 691-L, "Geology of the Lost Creek Coal Field, Morgan County, Utah," by Frank R. Clark, describing the rocks and coal resources of this region, may be had on application to the Director, U. S. Geological Survey, Washington, D. C.

EDITORIALS

Preparation of Bituminous Coal

WE PRINT on page 943 an article by Ernst Prochaska on the "Preparation of Bituminous Coal." This is the first of a series of articles on this subject, dealing mostly with the problem of coal washing.

While anthracite has been washed or mechanically picked for years, the advisability of subjecting bituminous coal to a similar treatment is in many instances an open question. In some cases the ridding of screenings of a few per cent. of ash by means of the coal jig increases the moisture content to such an extent as to largely nullify any benefits secured. In such an instance washing may be inadvisable.

On the other hand, some coals respond readily to the washing process and are consequently more desirable and efficient—and thus more salable—washed than unwashed. With the return to peace comes peace competition and, in an industry where the supply often equals or exceeds the demand, the operator will do well to avail himself of every means possible to insure a market for his product. There may be circumstances under which it might be advisable to wash all or a part of the output of a mine, even though no direct or tangible profit can be traced to the washery's operation.

Those operators who have been or are now considering the installation or operation of a coal washery will welcome these articles by Mr. Prochaska. While not exhaustive, they shed much light upon a subject that many of us understand only imperfectly.

McAdoo says that some railroad wages were scandalously low under private management. They were; and why? Because the Interstate Commerce Commission made rates inadequate. When the Government took over the railroads, rates were increased immensely; but even then the railroads were run at a loss.

The Integral Part

WE ONCE read a book in which a reporter, who had just interviewed a man of progressive ideas, said: "Why! That man's plans will take a thousand years to materialize." He wondered, as we did, how any man could look forward to so far-distant a future with any desire to aid in accomplishing the things which could not do him the remotest possible good.

And yet there is a certain type of mind that works with the full knowledge that what it strives to accomplish cannot, by any chance, come true within a lifetime. But in spite of that knowledge, such a one will work on, believing that he can hasten the coming of the thing desired, and knowing that with his help it will arrive a bit sooner. So he is willing to do his own, the integral, part with full faith.

That, we suppose, is the proof of a really unselfish ambition.

It seems as though most of us want something more tangible, and at least more nearly at hand than that which is not to be realized within a thousand years.

However, don't we all work unselfishly—to a certain extent? Do most of us see the final use that is made of our labors? For example, take those of us who help dig the subways of the big cities. Not many find that the great systems serve us, individually, after they are finished: but we have helped make it easier for those workers who have long distances to travel day after day.

Another instance: Consider those who are spending their days on some company's books, keeping accounts straight. They do not see the goods arrive and depart, though they figure on them, and speak of them daily; nor do they often see the actual money that is involved in the various transactions.

So, too, are we who work in the mines simply integral parts, expending the energy that comes to us, so that life may be made better for others and, eventually, for all those who are to come after us. Just as the men who make the tools we work with do not witness the use of their products, so we do not see the great boats that are propelled across the ocean, the great mills that produce the woolens we wear, nor many of the things that contribute to the world's good, though all these things have life partly because of our energies. But we do, nevertheless, know that we are helping in the great advance, the great march of progress, and that others are doing things for us—to lighten our work.

There are many working for us at the very time this is being written, and just at the moment this is being read. There are men even now who are trying to perfect experiments which will make the undercutting, the drilling and all the rest of it easier for everybody.

Let us try to do our part with a conscience. Let us try to make our output a product so clean and so solid in worth that those who use it will say: "Someone has done his job well, knowing that it would be appreciated. He must have been thinking of us."

Government regulation should regulate. It should not merely cut off the peaks of profit while leaving all the valleys of loss, but it should provide and assure an even return. If the public is to be umpire, it must be a fair umpire and not a prejudiced one. A guaranteed profit of 6 per cent. is one thing, a maximum profit of 6 per cent. is another.

Coal Export Waits on Shipping

GIVEN enough ships and a sufficiently low ocean freight rate, American coal producers not only can export a large volume of coal, but, what is more to the point, by so doing can bring to life the now listless coal industry. To make this latter statement clear, it must be remembered that not all the fuel mined here is suitable for export. In fact, the American coals that have found favor in foreign markets come from the

Pocahontas and New River fields of West Virginia. If we could export a large tonnage of this fuel, it would mean that coal mines in the Middle West would be enabled to work more regularly than they do now. Instead of demanding and receiving Eastern coals, consumers in Indiana and Illinois, for example, would be forced to burn fuel produced from mines in their respectives states.

The exporting of a large volume of coal, therefore, would stimulate the coal industry at home. Due, however, to a lack of bottoms and prohibitive ocean freight rates, American coal exporters find themselves in a peculiar, if not unpleasant, situation. Not only are they unable to accept or consider the many inquiries for coal coming from abroad, but, what is worse, they are compelled to stand by futilely and watch the trade they have succeeded in building up with South America slip back to England.

Already more Welsh than American coal is being unloaded at South American ports, and unless some concrete action results from the conferences now being held in Washington relative to the export of coal, Great Britain will regain most, if not all, of the South American coal business she lost during the war.

Although the prices of American coals at Hampton Roads are considerably lower than the prices of Welsh coals at Cardiff, this advantage is wiped out because it costs the American shipper $8 or $8.50 a ton more to ship his coal to South America.

Enough ships must be allocated for coal exports, and at rates that will enable us to compete with British shipping, if our foreign trade in coal is to be more than a dream.

If Walker D. Hines is willing to give the public transportation at a loss of $768,000,000 a year, why should not the steel corporations and the coal companies be equally generous with their money and give steel and coal to the railroads at a loss? The answer is easy: Walker D. Hines makes himself a good fellow with the money of the public, while the wicked steel and coal barons must spend their own.

Don't Yawn in Company; It's Impolite

TO YAWN in company is unbecoming and rude to those who happen to be present. Then, again, it's catching. However, it certainly is a relief to one's feelings.

Here is some more advice: Don't predict a business depression in company. It's unbecoming—the gloomy man is never liked. It's rude—a man who has no faith in the ability of his fellows to meet a little hesitation in business by plain reasoning and a gust of enthusiasm is a poor citizen.

And it's catching—most men don't think. They catch the "glooms." Conditions don't create them. It's the discouraging man who says, "Steel, yourself! It's not going to kill you," who robs the public of its courage. When a man who has the "glooms" appears, the thoughtless catch the disease by ordinary infection, and even the thoughtful get it by a process of false argument. "Surely," they say, "this man has seen something that I haven't seen. He knows his own particular business better than I do, and that being so he has been convinced that troublesome days are ahead. He is probably correct in his judgment or he would not have formed it."

Like as not, the man to whom the thoughtful men refer never saw a wraith himself but saw another man who had caught a glimpse of a third man who had been introduced to a fourth man who thought he had seen a wraith and was shaking with fear. So the word passes along that there are troubles ahead.

Thinking up what would come "after the war" has been a favorite parlor game since 1913. Most of the guesses have been wrong, and forfeits have been piling up. Between the hopeful, who imagined a new heaven and a new earth for labor and capital, and the depressed, who visioned a Dante hell for both, there lies an even course for sober men. Prices and wages are staying up or gently increasing. There is every reason for confidence. If only the wage and price reductionists would cease yawning in public and repeating to the assembled company: "I worked so hard yesterday. I knew I would be sleepy today."

It has been clearly proved that the Interstate Commerce Commission, as a body, was incompetent and unfair in handling the railroad tariffs before Government ownership was established. The incoming Congress should provide a successor with more judgment and force of character.

Six-Hour Day Only a Temporary Cure

A SIX-HOUR day might for a while create a decreased productive capacity, and so help the Middle West coal operations to obtain steady time. As a result the manufacturers of the Middle West would have to burn Middle West coal. Soon, however, there would be a large development in West Virginia and central Pennsylvania, because those regions could not fill their orders for high-duty coal without such development. Eventually the new mines in those regions would be so numerous that they could fill all the orders placed with them, and the Middle West business would return to its present stagnated condition.

The six-hour day is a temporary cure; it could not provide a permanent relief. Shortening of time and restricting of output are like morphine—they need renewal. They create a need as well as fill one. Take a little of them and you soon need more. If the hours are to be shortened or output restricted it should be for the improving of the physical, mental and moral well-being of the workingman, and not as an economic expedient; for, as such expedient, it will never be a success. It will produce an excess of mine development even in the Middle West, and so create a condition that will negative its own effect.

When we reduce hours let it be done by all together. Let the mine worker work as long for the shoemaker and the garment worker as they work for him. Let them exchange hour for hour. The mine worker is the brother of the shoemaker and garment worker and should give labor for labor to these men. Democracy demands it and fairness requires it.

Get your idle dollars working. Repairs, long delayed, should now be completed. During the war it was a virtue to delay repairs, to have shabby and even disorderly works. Now is the time to spend the money thus saved in putting plant and property in proper working order.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

When the war is over and a bituminous coal contract is made, let it be one so flexible that it will endure. Let it not be an ironclad contract that does not recognize changes in cost of living, but an agreement which will be automatically revised with changing values of the dollar.

The price of coal is none too large, but it is now, and will be always, a function of the wage paid. If that wage be raised, the price will rise, so why worry. If an increase is justified by a raised living cost let it be, not merely conceded after a struggle, but given as a matter of course.

Let a wage-revision feature be provided in the bond, as is already the case in British Columbia. Every agreement should be so worded as to avoid contingent injustices; then the tendency to break labor contracts will be checked. Some day the Government will order that the dollar have a certain relation to the cost of living as Prof. Irving Fisher advises, or will require that debts should be repaid and interest given in accord not with the face of the promise, but with regard to the real value of the money at the date of payment, as has been advocated by conservative economists in Breat Britain.

Arrangements like these will make strikes less frequent, will render business more steady and will secure to the saving working man, as well as the capitalist, the full value of his savings.

Only Local Strikes Now Occur

In every region the strikes and disagreements now occurring are of a purely local character and do not bode any general disturbance. Fortunately they are few in number. On May 10, 300 employees of the Racket Brook Coal Co., who suspended work to compel that concern to reinstate a motorman and brakeman, returned to work leaving it to their grievance committee in session with the company officials to settle the dispute. The Racket Brook miners, however, had really another matter for which they desired a favorable settlement.

Certain of the miners had been working in the Keystone workings where the area is under pressure and the coal easily removed. They demanded pay for solid-coal mining where such coal was encountered. The company apparently regarded all the work as the equivalent of pillar work, and as easy mining, and therefore payable at pillar-coal rates. The grievance committee could not get a hearing as to the complaint. The reinstatement difficulty only added to the friction experienced with regard to the rating of the work in the crushed area. In the final upshot the motorman, Kreech, was reinstated with pay in full and many other provisions made.

Miners Want Work on Idle Days

In the Hazelton region the miners are not disposed to lay down to the day workers and do not approve of being idle whenever the breaker is closed down. They have informed the C. M. Dodson Coal Co. that if they are not permitted to cut coal on idle days they will go on strike, tying up the Beaver Creek colliery indefinitely. They claim that they cannot supply the drivers if they are not given a chance to get coal ahead.

Umpire C. P. Neill, of the Conciliation Board, has handed down a decision in the case of certain miners employed at the Enterprise colliery in the Schuykill region. They held that they were entitled to share in an increase of $2 per day granted to the inside men of this particular colliery. Umpire Neill declares the men are contract miners, and as such are not entitled to share in the increase.

The protesting miners claimed that they were company men, while the company contended they were contract miners and as such were entitled to the 40 per cent. increase given to this class of employees.

Some parts of central Pennsylvania have been working very slowly. A report of May 12 says that the Rochester & Pittsburgh Coal and Iron Co.'s mine, Helvetia, has been averaging only one day a week and that the men are moving away to places where better time can be secured. Eriton, a mine operated by the Northwestern Mining and Exchange Co., a subsidiary of the Erie R.R., is receiving many of these men. Being owned by a large railroad without many mines to supply it with coal it has always had an enviable reputation for steady work. Some men are going to Onondaga mine near Sykesville, but there the lack of houses prevents any great influx of men.

Object to Low Railroad Coal Prices

President Keeney and Secretary Mooney of District No. 17 have addressed the following letter to Walker D. Hines, the Director General of Railroads:

"Upon information at hand we are compelled to protest vigorously against the action of the Baltimore & Ohio R.R. in contracting for coal at less than the government price. In information given out by Fuel Agent Foos, of the Baltimore & Ohio R.R., under date of Apr. 21, we find the following with an additional statement that there are some other contracts which have not been acknowledged and which will be given out later: The Franklin Coal and Coke Co., 300 tons per day at $1.75; Central Fairmont Coal Co., 100 tons per day at $2.00; Big Run Coal Co., 200 tons per day at $1.85; New England Coal and Coke Co., 250 tons per day at $1.90; Berryburg Coal Co., 50 tons per day at $1.85; Fairmont Big Vein Coal Co., 200 tons per day at $2.10; Meyersdale Smokeless Coal Co., 100 tons per day at $2.15; Big Chief Mine, 100 tons per day at $1.90.

"The Chesapeake & Ohio Railway Co. has two fuel mines of their own in this district, namely: Dorothy, W. Va., and Eunice, W. Va. Since the depression in the coal industry these mines have run practically every day, and other mines in their immediate vicinity are idle.

"We feel that, regardless of the fact that these mines belong to the Chesapeake & Ohio Railway Co., the work should be more evenly distributed to other mines in that vicinity and that they should be given the opportunity to produce their proportion of the fuel consumed by the railroad. The prices quoted above are all less than the government price, set by the United States Fuel Administration, and are below the cost of production, based on the wages now being paid.

"If the railroad administration maintains its attitude by signing contracts for prices below the cost of production, it is only a matter of time until the operators signing such contracts will undertake to reduce wages and thereby bring about industrial disputes, which is just what we wish to avoid, if possible."

Local Disagreement Closes Mine

The Park City mines in Utah are reported all closed as the result of a strike. About 1000 mine workers in that region want a six-hour day and a wage of $5.50 a day. Park City is in Summit County, 21 mi. east-southeast of Salt Lake City. Little has been stated of it as a coal center, and the area referred to by the name of the Park City district may be an extension of the Cumberland, Wyo., field to the northeast. The pumpmen in the Ontario mine, it is said, left their pumps unattended, May 7. Flooding of the mines is likely to follow.

The Miner Cannot Live Unto Himself Alone

The miner produces coal for other workingmen to use for heating their houses. Some of it is used to feed boilers, which make the steam that, in its turn, drives machinery that manufactures what workingmen will use. Knowing that this is true, the workingman realizes that he must not raise wages out of proportion to living costs. If he does, the real (or ultimate) consumer of his coal, who is another workingman like himself, will not only have to pay more for it and for what is produced through its use, but will have to pay more than he should.

Discussion by Readers

Waste of Coal

Letter No. 5—A short time since several letters appeared in *Coal Age,* relating to wastefulness in the mining and marketing of coal. There is a great difference, in respect to waste, among the several mines, owing largely no doubt to the different conditions existing in those mines. To a very considerable degree, however, undue waste can be attributed to the negligence of miners and mine officials, improper methods of mining, or a reckless desire to produce a large tonnage regardless of the future working of the mine.

While some mines are recovering relatively 100 per cent. of the coal in their property, others are extracting little more than 50 or 60 per cent. In most of the latter cases, a far greater percentage of extraction could be obtained if more time and care was given to the preparation of a proper working system, adapted to the particular conditions at hand.

The desire of the management to produce a large tonnage quickly often leads to the unwise robbing of pillars that are needed for the protection of adjoining workings and results in the loss of much coal that can never be recovered. The same is true when a foreman is desirous of making a good showing on his daily tonnage sheet. If it were not for these reckless methods, many mines could increase their percentage of recovery 20 or 25 per cent.; but, to do this, more attention must be given to a uniform development.

Advantage of Estimating Coal in Acres

The custom too largely prevails of estimating a newly acquired coal property as containing so many acres. If the property in question was estimated on a tonnage basis, it would have the effect of emphasizing the fact that it is important to send every ton of that coal to the surface. In the estimation of *acreage,* a pillar more or less left in the mines and lost appears of little significance, being so small a fraction of the acre that it is ignored as inappreciable. But, when it is remembered that this small pillar left behind means a loss of 200 or 300 tons of coal, the fact has a deeper meaning.

Again, estimating in *acres* suggests to the mind the purchase price per acre; while estimating in tons involves the price per ton that the coal will bring when loaded at the tipple. Mining men know that there is a vast difference between the value of coal in place and its market value after it has been mined.

Consider for a moment the loss of a single pillar left in the mine and representing a value of $200 or $300 and then think of the larger loss resulting when many of these pillars are lost beyond recovery, through improper methods of mining or undue haste in increasing the output of the mine. The attitude of many a coal operator, in this respect, is quite similar to his habit of thinking that the coal burned under his boilers costs him nothing.

In this connection let me urge that every foreman be made to estimate the coal in the supporting pillars in his mine, by its value on the tonnage basis. It will give him a greater incentive to get out every ton of coal in such pillars; and he will put forth more strenuous efforts to do this, knowing that the track, power and drainage lines, timbering and other requisites are all at hand, and every ton of coal recovered from the pillars is so much clear gain. The lack of thoroughness in coal mining is the great underlying secret in the matter of waste that we are considering.

Wasteful Methods of Burning Coal

There is a great deal of truth in the fact often mentioned that a far greater waste of the energy of coal occurs in its transformation into power. Some are even inclined to hold the opinion that it is needless to trouble oneself about the loss of coal in mining when such wasteful methods are employed as are in use at present for the production of power. Few people realize how large a percentage of the energy of the coal burned in the furnace passes up the stack, instead of being utilized in the production of steam. This loss, however, is the engineer's problem and in no way concerns the waste of coal in the mines.

The incident cited by Joseph R. Thomas, in his letter on this subject, *Coal Age,* Jan. 16, p. 160, illustrates in a striking manner the large loss of coal that often occurs through the negligence of miners. He instanced two men working in adjoining rooms and mining their coal under like conditions. One of these men produced 43 more cars, in driving his chamber, than the other whose failure to do the same represented a loss for which no excuse could be offered. It is a difficult matter to discuss the needs of uniform methods of mining with men unless they can be brought to see the advantage to them on the tonnage sheet.

Exhaust from Steam Pump

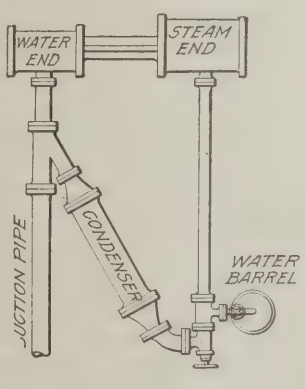
Letter No. 5—Referring to the inquiry that appeared in *Coal Age,* Mar. 20, p. 549, relative to exhausting a steam pump into the suction line, let me give a little of my own experience in that matter, which may be of interest to some readers.

Starting from the foot of the shaft, in our mine, the main entry was driven on a considerable dip, which continued for a distance of 500 ft. As the entry advanced, sumps were sunk in the floor near the face, and a small pump was located at the shaft bottom to draw the water from the entry and discharge it into the sump in the shaft, under the cage.

This pump was a small double-acting pump, having a 2-in. suction and 1½-in. discharge. It was supplied with steam through a 1-in. pipe line run down the shaft. The plan worked well, for a time, until the entry had advanced so far that the pump gave poor service, owing to the increased length of the suction line. It was then moved to the foot of the dip, 500 ft. distant from the shaft. The former suction line now became the dis-

charge, and a new sump, 4 x 5 ft. and 3 ft. deep, sunk just below the pump, improved the service.

What was peculiar about this arrangement was the fact that I could pump water into the sump or out of it as I chose. I ran a short pipe, from a tee in the discharge line, to the sump. Another short pipe was run from the suction line into the sump, while the exhaust port of the pump was fitted with a pipe that entered the suction line about 4 ft. from the pump. Suitable valves were provided in these pipes so as to control the action of the pump in any manner desired.



In starting the pump, the valves were arranged to exhaust directly into the sump; but when the pump had caught the water and was working properly the exhaust was turned into the suction line. It frequently happened that the steam exhausted into the sump while starting made the water very hot. But, in that case, I could pump it out and fill it again with cold water. The scheme worked well and all the trouble I had was that it was necessary to watch and stop the pump before it got out of water. If this was not done, the hot exhaust steam would find its way into the discharge line, expanding and throwing the pipe out of line.

Shelburn, Ind. R. J. PICKETT.

[The plan outlined by this correspondent appears to have for its chief object the cooling of the water in the sump, from time to time, by allowing water from the discharge line to flow back into the sump. The scheme is open for discussion.—EDITOR.]

Letter No. 6—The discussion of the question of disposing of the exhaust steam from a pump located in a mine recalls a scheme that I employed some years ago to get rid of the steam exhausted from a pump located at the foot of a mine slope.

In that instance, I adopted the plan shown in the accompanying sketch. We utilized a 9-ft. length of old pipe of twice the diameter, or four times the area, of the suction pipe of the pump and rigged it up to serve as a condenser. The arrangement is illustrated in the figure. It will be noted that the exhaust pipe, from the steam-end of the pump, is connected with one end of the condenser, the other end of which is joined to a Y in the suction pipe, at a point from 6 to 9 ft. away from the water end.

The position of the condenser, as shown in the sketch, was such as to cause the steam exhausted into it to assist the flow of water in the suction pipe. Entering the pipe at an angle of 45 deg. gave far better results than if this connection had been made at right angles, or in other words, if a T had been used instead of a Y connection.

In order to start the pump properly, it is necessary to have two valves on the exhaust pipe. When starting, and until the pump has caught its water, the valve leading to the condenser is closed and the other valve opened, which permits the steam to exhaust into the water barrel shown in the figure. But, after the pump has started and is drawing its water the first valve is opened and the second closed. The steam is now exhausted into the condenser and passes into the suction pipe as water.

I found that this arrangement not only got rid of the steam, which was a great annoyance in the mine, but the capacity of the pump was greatly increased, in respect to the height of the suction lift. I consider this arrangement very practical PUMPMAN.

McKeesport, Penn.

Longwall Work in Low Seams

Letter No. 1—Referring to the proposed modified longwall system described by Charles Martin, *Coal Age*, Mar. 20, p. 520, permit me to say that I cannot understand his reference to "big, heavy cumbersome machinery to be moved in following up the face," in a regular longwall system. It hardly seems possible that he can refer to the common belt conveyor that is so generally used on a longwall face in working a low seam of coal. There is no difficulty in moving such a conveyor forward, the work requiring a minimum of labor.

Instead of using a belt conveyor, Mr. Martin suggests installing a small rope haulage on each heading, for the purpose of operating a scoop having a capacity of 1 ton of coal. According to his description, the scoop is to be drawn back and forth along the face, by means of ropes operated by the hoist.

This reference recalls to my mind a "Thompson conveyor" that I saw working very successfully in a mine, some years ago. It consisted of from four to six low pans or slips made of sheet steel and supported with angle iron. Each pan was 5 ft. long and 2½ ft. wide, and these were coupled together and hauled back and forth, along a 300-ft. face, by means of a light haulage rope, after the manner of a main- and tail-rope system. One rope was attached to the front end of the first pan and the other rope passed over a tail sheave and was then attached to the rear end of the last pan.

SCOOPS NOT ADAPTED TO SOFT OR UNEVEN BOTTOM

This scheme worked successfully, in the case mentioned, because the bottom was smooth and presented no obstruction to the sliding pans. My great objection to the use of a scoop, in the manner described by Mr. Martin, is that if the floor was at all soft or uneven it would interfere with the success of the operation. Again, if the seam contained partings that had to be separated from the coal, there would be more or less of such foreign matter picked up by the scoop and loaded out with the coal. That would be particularly true if the scoops were to be loaded after the manner of the scrapers commonly used in grading and excavation work on the surface.

One of the advantages claimed for Mr. Martin's proposed method is the oblique face he has mentioned and which is shown in the cut on page 520. For my part, I fail to see the necessity for it, and believe there would be danger of the roof pressure crushing the coal at the angle where the two oblique faces meet. It might even happen that the settlement at this point would bind and hold fast the cutterbar of the machine. The cost of working would also be greater by this method than with a single 300-ft., straight, longwall face extending between the two main roads or headings.

In over 20 years' experience in longwall machine mining, I have found no difficulty in controlling the fracture of the roof when operating a 300-ft. face between two main haulage roads. I believe that it is all a question of systematic timbering and building the necessary

wood chocks on a bedding of slack about a foot in thickness. These chocks are taken down and carried forward as the face advances.

Regarding coal-cutting machines, let me say that the longwall machine has a decided advantage over the shortwall machine, for this work, as it requires only a clearance of 2½ to 3 ft., in width, along the face, as compared with the 6-ft. clearance required to operate a shortwall machine.

Referring once more to the plan illustrating Mr. Martin's proposed method, I cannot see how the roadway marked "line room" is going to be kept in good condition to serve as a return airway, unless a solid pillar of coal is left between this road and the longwall section. In the description, no mention is made of the thickness of the seam or the character of the underlying and overlying strata, or whether the mine is dry and gassy or the workings wet, all of which have a considerable bearing on the best method of mining in the longwall system. ANDREW ORR BAIN.

McKeesport, Penn.

Roof Conditions in Longwall Work

Letter No. 3—In answer to the inquiry of "Sandrock," *Coal Age*, Mar. 27, p. 591, regarding the conditions presented by a hard sandrock roof, in mining coal by the longwall system, I desire to submit the following as a result of my own experience in mining coal by longwall, under conditions somewhat similar to those he has mentioned:

Wherever practicable, in the working of a low seam such as this, at least 2 ft. of roof should be taken down and built into uniform packs on each side of the roadways leading to the working face. If there is sufficient material for the purpose, an extra pack 6 ft. wide should be built about midway between adjoining working places. These packs in the gob or waste, however, must not be made too solid, as that would have the effect to throw too great a weight on the roadpacks and the working face, which would have a tendency to cause the floor to heave on the roads and might produce a disastrous break in the roof, at the face.

DANGER IN DISTURBING BOTTOM LIABLE TO HEAVE

Whenever the floor in a mine has a tendency to heave it should be left strictly alone; because, when once broken, the heaving will continue to increase and may be so rapid, at times, that great difficulty will be experienced in keeping the track in shape and maintaining the necessary headroom for the cars to travel. This applies particularly to a fireclay bottom, where the mine is wet.

An important feature in the proper control of the roof, under the conditions here described, is to withdraw all posts and other timber from the waste. My practice is to build cogs only at the face, my experience is that few if any wood packs should be built, in longwall work, with the idea of leaving them in permanently. The wood packs sometimes built alongside the roadways offer a much greater resistance to the roof than stone packs, which tends to throw more weight on the face than is necessary to break the coal, and presents the danger of causing a break in the roof at the face.

Where stone packs are built uniformly, in the manner in which I have described, and no timber is permitted to be left in the gob, the result will be that the roof and floor will come together gradually back in the waste, which is absolutely essential in all successful longwall work.

Let me state, here, that wider packs must be built and more roof taken down on main haulage roads than in the working places. However, my experience is that these packs should all be built of stone, in order that a small uniform resistance will be presented everywhere and better results be obtained in the settlement of the roof. In my opinion, everything depends on this uniformity of the packwalls protecting the haulage roads and working places. HARRY MARSON.

Martins Ferry, Ohio.

Panel System of Mining

Letter No. 4—Kindly permit me to refer to the letter submitted by a mine foreman of Clinton, Ind., which appeared in *Coal Age*, Apr. 10, p. 680, and discussed the panel method proposed by R. J. Pickett, in the issue, Feb. 27, p. 419, regarding which he asked for suggestions.

While this foreman, in discussing the driving of entries and rooms in panel mining, offers much sensible and friendly criticism and makes many good suggestions that are practical, his idea of driving rooms only 22 ft. wide could not be applied to our mines here in Sullivan County, under the present agreement with the United Mine Workers of America.

In Indiana, entries are driven under what is known as the "Syndicate system," by which three men will drive two entries and turn the roomnecks, to do which they will be given the exclusive use of a mining machine. Syndicating a room, however, is considered contrary to the agreement with the union and is not tolerated.

CONDITIONS IN SULLIVAN COUNTY, INDIANA

But, the 18-ft. air-course proposed by Mr. Pickett would be considered as a room and not an entry, and trouble would also arise, under the present agreement with the union, regarding the suggested 22 ft. for the width of rooms. In Sullivan County, it is customary for two men to work two places, from 25 to 30 ft. in width, with tracks laid at the center of each place. Any less width than that last mentioned would require the giving of an extra place to every two men, and this would certainly operate as a disadvantage in the daily production of coal, or the tonnage per man.

Referring to Mr. Pickett's inquiry, I believe the operation of which he has charge is in the No. 5 vein, in Sullivan County. Inasmuch as I have had some experience, myself, in working that vein in the same county, I may be permitted to offer my views on his present system and the changes he proposes to make. Let me say, first, however, that I agree fully with the suggestion of the Clinton foreman, that the driving of an 18-ft. air-course, with only a 10-ft. pillar to protect it from the old workings, would certainly invite a squeeze that would prove expensive. Furthermore, the driving of such an air-course would also act to retard the development of the room entries, since the rooms would be driven nearly as fast as the entries.

In describing his present method of working, Mr. Pickett states that cross-entries are driven off the main headings, about 1000 ft. center to center, thereby giving space for the turning of 22 rooms on 40-ft. centers, besides making allowance for solid pillars of coal protect-

ing the cross-entries. It is possible for a Sullivan longwall mining machine, such as Mr. Pickett states he is using, to cut about 20 places in a single shift. But, in my opinion, by the proposed method of working, it will hardly be possible to keep that number of places going on a single heading, owing to the slow development.

To illustrate, let me say that two men work in two 25-ft. rooms and two entrymen are driving a 12-ft. entry and an 18-ft. air-course, asuming, for argument, that this is permitted under the agreement with the union. Now, assuming that both men mine and load an equal amount of coal, it is evident that the places will advance in the inverse ratio to their widths. This being the case, the total width of entry and air-course being 30 ft. and that of two rooms 50 ft., while the rooms are advancing 30 ft., the entries will advance 50 ft. Assuming that work is started in the first two rooms as soon as these are turned and that the rooms are to be driven, say 180 ft. from the point they are widened out, to the pillar flanking the next air-course, it is evident that the entrymen will be only 300 ft. in advance of the last room turned, when the first two rooms are finished. But such an advance will only allow for the turning of eight rooms on 40-ft. centers.

A Better Plan Suggested

In my view, there are two exceptions to Mr. Pickett's present panel system. Let me suggest that, instead of turning cross-entries off the main entry on 1000-ft. centers, this distance be increased to 1200 ft. Then, allowing for 100-ft. pillars protecting the cross-entries on each side of this block, there will be room for driving 26 rooms on 40-ft. centers.

Again, let me suggest the driving of room headings off both entries of each pair of crossheadings. For example, the crossheadings being driven east and west, drive No. 1 and No. 2 N off the 2 E or 2 W, as the case may be, and also drive Nos. 1 and 2 S off the 3 E or 3 W to meet the corresponding entries driven north. In my opinion, this system would not only give ample room to keep the machines running at full capacity, but would expedite the recovery of coal from the last room on the heading, which is now difficult to secure. The system would also speed up development and reduce the cost of upkeep on roads and entries.

The chief disadvantage, in the method I have mentioned, is the increased length of haul on the entries driven south; but this objection is more than balanced by the rapid development and increased output of the mine.

In conclusion, I may say that our roof, in this vein, about 6 ft. above the coal, is impregnated with marsh gas and contains quite a little water. Instead of pulling pillars, therefore, every effort is made to avoid caving the roof; and, because the fireclay bottom yields readily to the softening action of water and heaves, it is important to keep the workings well drained by providing an adequate pumping equipment. MINER.

Sullivan County, Ind.

Efficiency of Mine Officials

Letter No. 10—I have been greatly interested in the letters that have appeared recently in *Coal Age*, relating to the efficiency of mine officials. While I cannot say that I agree with everything that has been written, no doubt exists in my mind but that there is ample room for greater official efficiency in coal mining.

As remarked by Thomas Hogarth, in his excellent letter, *Coal Age*, Mar. 13, p. 504, "A good superintendent shows his ability by the foremen he employs." In Colorado, the state mining law compels the employment of a man as foreman, who holds a first-class certificate. It may chance, however, that the holder of such a certificate does not prove to be a good foreman. He may have the knowledge of what should be done, but not possess the ability to successfully direct his men and secure the best results.

When a foreman fails, the superintendent has an opportunity to show his own ability to supervise the work, as it is not always an easy task to displace a foreman after he has once been given charge of a mine, unless it should happen that the mine inspector would find fault with him.

Yes, the superintendent must not only select the right man to act as foreman, as Mr. Hogarth has said, but he must get the right kind of material and supplies for the mine, and know how to keep the men satisfied. In a word, he must possess the knowledge required to operate the mine in compliance with the law and get results.

Speaking of a superintendent's wearing a "white collar," to my mind, is not material to the question of his efficiency. The real work of a superintendent is to so organize and control his men as to get results. Our great General Pershing demonstrated *his* ability as an organizer and a leader of men. He was not the kind of man that would shoot a hole in a barn and paint a target around it, but by plugging a bull's eye in the target already painted he has proved his marksmanship. That's efficiency in any leadership, and gold medals and white collars cut little figure one way or the other.

Examination for Superintendents

In the operation of coal mines, it is my honest opinion that superintendents should be compelled to pass an examination before a state mining board—not to say that that would make them more efficient as mine superintendents—but it is often necessary for a superintendent to act in the capacity of mine foreman, in the latter's temporary absence from the mine.

For a superintendent to act as mine foreman, however, would not be in compliance with the Colorado mining law, unless he was already in possession of a first-class mine foreman's certificate as required by law. It is true that our law, at present, grants a mine superintendent the privilege of acting as foreman if he can prove his ability to perform those duties; but it would save a lot of argument on this question if the law provided for the certification of superintendents.

Mention has been made of "a barber," in one instance, and "a grocer," in another instance, becoming efficient superintendents of large mines. In my opinion, it is the education and knowledge of the man that fits him for this position. One of the most successful superintendents in this part of the country was formerly a machinist. His education had taught him the general principles of mining, including surveying, reading of maps, and accounting of labor and supplies. This knowledge, together with his ability to organize and lead men, resulted in the coal coming out of the mine in a way that satisfied the men higher up.

I fully agree with the suggestions that have been made that the superintendent should have no favorites, but should treat all men alike and refer all complaints

to his foremen. A superintendent's interfering with a foreman's decision, or in other ways assuming the duties that are the foreman's can only do harm. It has often caused a good foreman to quit his place.

Let me say, in closing, that the mine officials' "Round Table," for the discussion of matetrs pertaining to mining, is a great factor in increasing official efficiency. A man with 90 per cent. brains and 10 per cent. common sense cannot prove efficient in a mine; he must have 50 per cent. brains and 50 per cent. common sense, and the round table helps to make such men. It is there that John Jones can show Jack Smith his method of calculating a switch; while John Smith, in turn, will show his friends how that switch must be laid in the mine.

In the monthly or semimonthly meetings of the mine officials, the efficient superintendent will lead in all discussions, and thus be able to develop the best thoughts and ideas of each man present, and give to all the same aim and object. It has been my good fortune to come in contact with superintendents of this class, who appreciate the suggestions of their men concerning any improvement in the getting out of the coal.

Farr, Colo. ROBERT A. MARSHALL.

Letter No. 11—After reading with deep interest the letter of J. T. Jones, *Coal Age*, Mar. 20, p. 548, I beg to differ with him in regard to the opinion he has expressed that coal operators only consider that official efficient who produces a large tonnage of coal at a low cost of operation, without regard to the actual conditions surrounding the work.

Observation has led me to believe that coal operators and the higher officials of companies, today, know just what conditions are confronting their men in charge of the underground work. To me at least, it is inconceavable that any intelligent officer of a large coal company will expect a man whom he has placed in charge of a mine where he knows there are peculiar difficulties to be encountered, to make the same showing that is made in another mine that is reaping the harvest of its palmy days.

It is my belief that the management of coal mines determine the efficiency of their under-officials in accordance with the results they are able to produce in varying conditions. They are fully aware that coal can be produced with greater economy and safety in some mines than in others. From the abundance of literature published by mining companies on "Safety First," it is quite evident that it is the honest purpose of the management to keep their mines in a safe and healthful condition while producing a maximum tonnage at a minimum cost. Their plans and instructions show that due consideration is given to the lives of their men and the protection of property.

EFFICIENCY SHOWN BY ABILITY TO PERFORM

The proof of efficiency on the part of any mine official is readily estimated by observing the manner in which he meets the difficult problems that are constantly being presented in the operation of a mine. Contrast, for a moment, two officials in charge of mines working under widely different conditions. Let us say that the superintendent, at one of these mines, has been fortunate enough to break all preceding records in the daily output of the mine. At this juncture, however, he is suddenly puzzled by conditions that have developed underground, regarding a heavy squeeze, which threatens to close an entire section of the mine; or it may be an unexpected outburst of gas occurs in a portion of the workings. Suppose, now, that the superintendent's lack of practical experience in handling either of these conditions renders him helpless to cope with the present situation, the mine would then be forced to suspend operations for a time or until the difficulty can be overcome.

Compare the instance just cited with the situation at another mine where the superintendent is not only capable of producing a fairly high daily tonnage, but has, besides, the ability to safely handle all the difficult problems that are liable to arise in the mining of coal. In comparing these two cases, one can see plainly that the more efficient foreman or superintendent is the one last named. With such a man in charge, there is no need of going outside the organization for assistance to insure the safe operation of the mine.

The casual onlooker can readily determine the relative degree of efficiency of two or more officials in charge of mines, by observing how often or how seldom they are taken to task by the management for the results obtained. The more frequent visits of the higher officials to some mines than to others shows their greater anxiety in the one case than in the other; or it may reveal a greater lack of confidence in the men in charge of the one mine than in those at the other mines.

OBSERVATIONS OF A GENERAL MANAGER

My attention was called to this fact through a conversation with a general manager of a large coal company. In speaking about the visits he paid to his different mines, he said, "It all depends on the colliery superintendent and foreman. I am very proud of the team of officials I have at ——— mine, because I know that everything must be all right with them, as their production shows it and the amount of supplies consumed is very low."

"Moreover," he continued, "the mine inspector's reports were such that I had to sit up and take notice. Just think of it—not a man has been injured in that mine for a whole year; and the report of men being idle, owing to unfavorable or unsafe conditions in the mine, is lower than at any other colliery the company operates."

From these statements, it appears to me that "efficiency" should be the middle name of the superintendent and foreman of the mine just mentioned. It is apparent that they are men who are constantly observing and trying to improve conditions bearing on the daily production of the mine, as well as improving the working conditions, which is and always should be the most important item in every industry, and is generally known as the "conservation of man power."

Allow me to close, then, by saying that the true efficiency of mine officials must be determined by taking into consideration something more than their ability to produce a large tonnage at low cost. Any broad-minded manager, in discussing the efficiency of his under-officials, will ask, "How are they producing the coal? What conditions are the men working under? What evidences are there that the men are satisfied?" The answer to these questions will determine the degree of efficiency of the men in charge at the mine.

Plymouth, Penn. JOSEPH R. THOMAS.

[This letter will close the discussion on "Efficiency of Mine Officials"—EDITOR.]

INQUIRIES OF GENERAL INTEREST

ANSWERED BY JAMES T. BEARD

Effect of Hoisting on Ventilation

We have under consideration, at the present time, a proposition regarding which I would like to have an expression of opinion, by *Coal Age* and readers who have had actual experience in a matter such as I am about to mention.

The upcast shaft, at our mine, is 10½ x 16½ ft. in section and 360 ft. deep. The air current passing up this shaft has a velocity of 1000 ft. per min. It is proposed to equip this shaft for hoisting coal and to employ self-dumping cages for that purpose. The bottom area of each cage will be 6 x 10 feet.

In turning over this proposition in my mind, the question has arisen, What effect will the movement of the cages in the shaft have on the quantity of air in circulation in the mine? It is estimated that the proposed tonnage of this mine will require making 1000 dumps in 8 hours, which will necessitate hoisting at the rate of 30 ft. per sec. I want to ask if this arrangement will interfere with or tend to lessen the quantity of air that is now passing up this shaft. OPERATOR.

Pittsburgh, Penn.

This is a question that has often been asked and must be answered with due regard to the existing conditions. The correspondent has given the sectional area of the shaft and the area of the bottom of each cage, and it is clear that this is a double hoistway, one cage ascending as the other descends the shaft. He has not stated, however, whether the floor of the cage is solid or formed of slats or bars that would permit the passage of air through the floor and present less obstruction to the air current.

Again, it is not stated what form of partition divides the two hoistways, whether this is made of solid planks completely separating the two compartments of the shaft, or whether cross-buntons are used, spaced at wide intervals apart. These details have an important bearing on the question of what effect the movement of the cages in the shaft will have on the circulation of air in the mine.

It is the experience of the editor, in the operation of a mine in the west where a double-compartment hoisting shaft was used as an upcast for the mine and there was ample room between the cages and the shaft curbing and the bottoms of the cages were slatted that there was no perceptible obstruction to the air current passing up the shaft. But, in that case, the two compartments of the shaft were separated by an open partition formed of buntons spaced six feet apart.

In another instance, where the cages fitted quite snugly in the shaft and the compartments were separated by a solid partition wall of planks, the effect on the circulation was such as to necessitate opening the bottoms of the cages and removing many planks from the partition in the shaft.

Theoretically, in a double-compartment hoisting shaft, the air is churned back and forth between the two compartments, as the two cages act alternately to retard and to assist the flow of air, up the shaft, which would suggest that the result of the moving cages on the circulation in such a shaft is *nil*.

Practically, however, it can be said that everything depends on the open partition and the amount of space between the cages and the shaft-curbing. The latter appears to be ample in the case presented in the inquiry of this correspondent.

Laying a Room Switch

Kindly describe the manner of locating a frog on an entry when laying a room switch where the rooms are turned at right angles to the entry, and say how far back on the entry should be the point of switch.

What number of frog should be used in laying such a switch where a gathering motor is to be used and it is necessary to take the motor to the faces of the rooms? Is there any formula that will give the dimensions necessary in laying this switch? W. G.

———, Penn.

It is common mine practice to use a No. 3 frog in laying a room switch where the room is turned at right angles to the entry. When the switch is properly laid, and the track well ballasted, a gathering motor will pass over this frog without difficulty.

Start by sliding the frog along on the near rail of the entry, to such a position that there will be a good clearance for the car at the corner where the outby rib of the room intersects the rib of the entry. This corner can be rounded to a considerable extent, ordinarily, without endangering the support of the roof over the roadway. The distance from this rounded corner to the point of frog must be equal to half the gage of the track, plus half the width of the car, plus the desired clearance.

Thus, allowing a clearance of 6 in., the width of the car being 5 ft. out to out, and the track gage, 3 ft., the distance from the coal to the point of frog must be 4½ ft. In a 10-ft. entry the point of frog will generally be about on line with the outby rib of the room. Rounding the corner will assist in reducing the sharpness of the curve passing into the room, beyond the frog.

The distance to be measured back on the entry, from the point of frog to the point of switch, is usually taken as equal to twice the gage multiplied by the number of frog. Thus, for a 3-ft. gage and a No. 3 frog, the distance would be $2 \times 3 \times 3 = 18$ ft. This is practically the length of the lead rail of the switch and the middle ordinate of this curved rail is about 9 in.

After passing the frog, the curvature of the rails must be increased to enable the car to clear the inside rib, in the mouth of the room, and bring the room track in line with the straight rib. There is no formula for calculating the amount of this curvature, which can only be determined on the ground, by making the curve as uniform as possible.

EXAMINATION QUESTIONS

ANSWERED BY JAMES T. BEARD

Miscellaneous Questions

(Answered by Request)

Ques.—The total ventilating pressure in a mine, the sectional area of which is 48 sq.ft., is 374.4 lb.; what is the reading of the water gage?

Ans.—The sectional area of the airway being 48 sq.ft., the unit of ventilating pressure is 374.4 ÷ 48 = 7.8 pounds per sq.ft. and, since 1 in. of water gage corresponds to a presure of 5.2 lb. per sq.ft., this pressure will give a water-gage reading of 7.8 ÷ 5.2 = 1.5 in.

Ques.—The volume of air passing through a mine is 150,000 cu.ft. per min. A test of the return air shows 0.35 per cent of methane; what amount of gas is given off in 24 hr., assuming conditions to remain unchanged?

Ans.—From the reading of the question, it must be assumed that the circulation given is the quantity of air entering the mine. Then, since the test of the return air shows 0.35 per cent. of methane, the proportion of fresh air in that current is 100 — 0.35 = 99.65 per cent. Therefore, 150,000 cu.ft. is 99.65 per cent. of the return current, and the total quantity of air and gas in the return is 150,000 ÷ 0.9965 = 150,268 cu.ft. per min. The quantity of gas given off each minute is, then, 150,268 — 150,000 = 268 cu.ft., and the quantity generated in 24 hr. is, therefore, 268 × 60 × 24 = 385,920 cu.ft.

Ques.—(a) What is meant by horsepower on the air? (b) If the volume of air entering a mine under a 2-in. water gage is 84,615 cu.ft. per min., what is the horsepower on the air?

Ans.—(a) The horsepower on the air is the total effective work concerned in producing the circulation of the air current, estimated on a basis of 33,000 ft.-lb. per min. as the equivalent of one horsepower.

(b) The effective work performed in the circulation of an air current is equal to the quantity of air passing, in cubic feet per minute, multiplied by the unit pressure or the pressure per square foot producing the circulation. In the case given, the effective work is 84,615 × 2 × 5.2 = 879,996, say 880,000 ft.-lb. per min., and the horsepower on the air 880,000 ÷ 33,000 = 26⅔ hp.

Ques.—An anemometer registers a velocity of 30,000 ft. per hr., in an airway 5 x 8 ft. in section. What is the volume of air passing per minute, and how will you ascertain whether the anemometer is in good working order?

Ans.—The velocity given as 30,000 ft. per hr. is 30,000 ÷ 60 = 500 ft. per min. The sectional area of this airway is 5 × 8 = 40 sq.ft., and the quantity of air passing is therefore 500 × 40 = 20,000 cu.ft. per min.

In order to ascertain the correctness of the anemometer, it should be sent to the factory where it was made, to have its calibration checked in an accurate manner. A rough test may be made in the mine by selecting a straight and uniform stretch of airway and applying the smoke test.

A distance of 100 yd. is first measured along an airway in which a fair quantity of air is passing. The operator, holding the instrument at the intake end of this measured distance, sets off a little flash of powder, while an observer at the other end of the measured distance notes the exact time between observing the flash and the first smell of powder that reaches him, and signals the operator. The latter then takes the exact reading of the instrument, which should correspond to the distance measured if the instrument is correct.

Ques.—In a lever safety valve, the whole length of the lever is 30 in., the distance from the fulcrum to the valve stem, 3 in., diameter of valve 2 in.; what weight must be put at the end of the lever to have the valve blow off at a pressure of 40 lb. per sq.in.? Also, where should this weight be hung on the lever so that the valve will blow off at 30 lb. and again at 20 lb. per sq.in.?

Ans.—The area of the valve is $0.7854 \times 2^2 = 3.14$ sq.in. For a pressure of 40 lb. per sq.in., the total pressure on the valve is $40 \times 3.14 = 125.6$ lb. Now, to ascertain what weight will be required on the end of the lever to balance this pressure, it is necessary to apply the principle of moments, which makes the product of the weight (W) into the length of the lever equal to the product of the total pressure on the valve into the distance of the valve stem from the fulcrum. Thus,

$$30\ W = 3 \times 125.6 = 376.8$$
$$W = 376.8 \div 30 = 12.56 \text{ lb.}$$

Again, to find the distance this weight must be hung from the fulcrum, in order that the valve shall blow off at 30 lb. per sq.in., we have by the same principle of moments, calling the required distance x,

$$12.56x = 3(30 \times 3.14) = 282.6$$
$$x = 282.6 \div 12.56 = 22\tfrac{1}{2} \text{ in.}$$

For a blow-off pressure of 20 lb. per sq.in., we have

$$12.56x = 3(20 \times 3.14) = 188.4$$
$$x = 188.4 \div 12.56 = 15 \text{ in.}$$

Ques.—A fan driven by two coupled engines, having cylinders 18 in. in diameter, length of stroke 42 in., number of strokes 50, with 16.8 lb. pressure, giving 80 hp. and circulating 144,055 cu.ft. of air per minute gives an actual water gage of 3 in. Find the theoretical water gage.

Ans.—Assuming that this duplex engine, having the given dimensions and running at the given speed, under a mean-effective pressure of 16.8 lb. per sq.in., is developing 80 hp. when circulating 144,055 cu.ft. of air per minute, the theoretical water gage would be

$$w.\ g. = \frac{33{,}000H}{5.2Q} = \frac{33{,}000 \times 80}{5.2 \times 144{,}055} = 3.5 \text{ in.}$$

[Taking the given pressure as the mean-effective pressure in the cylinder, a duplex engine, having the above dimensions and speed, would develop only 45 hp., making no allowance for efficiency.

$$H = \frac{16.8 \times 3\frac{1}{2}\ (0.7854 \times 18^2)\ 50 \times 2}{33{,}000} = 45+ \text{ hp.}$$

As a matter of fact, in this case, however, the horsepower developed for driving the fan being given, the dimensions and the speed of the engine do not enter the solution and are misleading, owing to the fact that they do not give the horsepower mentioned.—Editor.]

FOREIGN MARKETS AND EXPORT NEWS

EDITED BY ALEX MOSS

Coal Shipments to Scandinavia and Holland

The War Trade Board on May 14 announced that henceforth applications will be considered for licenses to ship coal to Norway, Sweden, Denmark or Holland without requiring the importer to procure an import certificate. Applications for such licenses should be filed with the War Trade Board, Washington, D. C. The details of these applications will be cabled to the Inter-Allied Trade Committee in the country of destination, and with their approval a license will be issued. Under the foregoing ruling, shipments of coal need not be consigned to any association, but may be made directly to individuals in the countries of destination.

Larger Exports of New River Coal

Mine owners operating in the New River district gave it as their opinion that there would continue to be a larger amount of coal exported during the next few months than had been possible in the last few monthly periods, stating that during the week ending May 10 there had been a large increase in the tonnage shipped to tidewater for consumption in European countries. The statement was also made by New River operators that ships were somewhat easier to obtain than had heretofore been the case, that being attributed to the fact that not so much food was now being exported and that ships had been released for the carrying of coal for which there was an urgent demand in certain countries overseas.

English Coal Market

Business, in a general way, has been virtually suspended in the various coal markets, states the *Iron and Coal Trades Review* of Apr. 25, and under the prevailing holiday influence the few movements recorded have had little bearing on future trade prospects. Owing to lack of production in the Tyneside area, the outlook for neutral customers shows no improvement as to prospects of supply, and although orders are being steadily booked, buyers have to take the risk of getting deliveries.

In Yorkshire and the Midlands production has been well maintained, and the railways have taken full advantage of the larger tonnage available to add to their stocks. There are expectations that the embargo on exports may soon be removed, and the strong inquiry for the allies and the neutral countries should develop into an active demand for district hards. The demand for all classes of small steam sizes is active, but supplies are short. Nut slacks are also in good request, but it is impossible to obtain extra lots with the distribution so closely controlled. The better supply of domestic coal has enabled good deliveries to be sent, both to London and the nearer markets. The quieter demand for furnace coke is still experienced, but the position is met with a reduced output, which is readily disposed of.

the South Wales district there is very little doing on both the anthracite and steam coal markets, as the majority of the collieries are not at work.

The Scotch coal trade is still very fully employed, although there is not the same pressure as has been the case recently. Export business all round is still very much restricted on account of the difficulty of obtaining licenses. Steamers are kept waiting for cargoes a long time.

Shanghai Coal Market

Under date of April 10, 1919, Wheelock & Co. report that there has been little or no business in Japanese coal in Shanghai for some time. The only thing worthy of remark, according to the report, is the large number of arrivals bringing in over 67,000 tons of coal, which is apparently the result of the cheaper freight now ruling. In Japan quite a lot of business has been done in the commoner kinds of coal for industrial use, and this has had the effect of hardening prices on this class of fuel.

The spot demand for Fushun coal has grown considerably of late and it is therefore becoming increasingly difficult to supply the demand for export.

Owing to requisitioned vessels being released by the British Government it has been possible to reduce quotations on Kaiping coal, and such reduction has been extended to present contractors. The demands for the better grades exceed the supply, consequently prices for these coals are very firm.

Coal Situation in North China

[*North China Star*]

The five northern coal-producing provinces of Manchuria, Chihli, Shantung, Shansi and Honan yield about 60 per cent. of the total output for China. Present consumption of coal in the northern provinces is small, the annual consumption being one twenty-fifth of a ton per capita, as against 3½ tons per capita in America. Demand for fuel for household and industrial purposes is steadily increasing in China as the standard of living rises.

Manchurian coal does not come into other provinces of China on account of prohibitive freight rates. In Chihli, mines near Chinwangtao produce anthracite which sells at $13 to $14 a ton in Tientsin. Estimated cost of production, $6.50. The Kailan Mining Administration near Tangshan sells coal in Tientsin at $7.50 a ton. Cost of production, including freightage, about $3.20. The Min Tou Kou coal fields, west of Peking, where there are two companies operating on modern lines, produce second-class anthracite selling at $9 and over. Cost to Tientsin, about $2.30.

Bituminous and anthracite coal are also shipped to Peking from mines along the Peking-Hankow and Shih Chia Chuang railways. There are many small coal mines operated by natives in this district supplying local demand. Along this route is the Ching Hsing mine, a former German property, acquired by Japan, which supplies a Chinese railway car company with coal.

The Peking Syndicate, one of the most important concessions in China, sells coal at $18 a ton to Peking and Tientsin.

Deposits of coal in Shantung Province, while not so good quality as in Shansi, are easily worked and have foreign machinery. These mines supply local demand along the Tsin Pu Railroad.

BUNKER COAL

Maryland	28,636
New York	154,527
Philadelphia	39,853
Virginia	143,735

The governments of Great Britain and Spain have recently concluded an agreement under which the former allows the export of at least 150,000 tons of coal per month to Spain; the quantity will depend on the available shipping and on the cost of freights.

The imports of coal into Egypt during 1918 totaled 501,780 metric tons, as against 461,987 such tons in 1917 and 916,509 tons in 1916.

COAL AND COKE NEWS

What Happened in April

[The bracketed figures in the text refer to the number and the page of the volume in which references to the matter noted may be found and should the reader desire further information he can obtain it in the place indicated.]

Apr. 1—Frank J. Hayes, president of the United Mine Workers of America visits the White House and announces that his purpose is to call on President Wilson in Paris and urge his coöperation in the securing of increased sales of American coal in Europe.—West Virginia celebrates the second anniversary of the establishment of an eight-hour day for the miners of the state, at Rivesville, W. Va. F. C. Keeney, president of District No. 17, delivers an address [XV, 720].

Apr. 2—It is reported that a United States exporting firm has obtained an order for 4,000,000 tons of coal in Italy—Director General Hines of the Railroad Administration refuses to pay "stabilized" prices for rail—Southern pine lumber manufacturers refuse to "stabilize" their prices.

Apr. 3—The Anthracite Coal Operators' Association holds its annual meeting at the Bellvue-Stratford hotel in Philadelphia, Penn., electing officers [XV, 775]—The annual meeting of the Canadian Associated Coal Dealers is held at Toronto, Ontario, when the coal situation was fully discussed. Officers were elected and resolutions adopted [XV, 732]—D. E. Adams, a leading coal merchant of Winnipeg, Manitoba, dies at Pasadena, Cal. [XV, 733].

Apr. 4—Governor Sproul of Pennsylvania declares increase in anthracite prices is justified, attacking, however, railroad rate inequalities and retail delivery charges. He also urges public fuel markets.

Apr. 8—The air shaft at the Harry E. colliery of the Forty Fort Coal Co. is destroyed by fire, endangering the lives of 50 men underground. On the evening of the same day, the washery of the Red Ash Coal Co is burned. Its value was about $100,000 [XV, 774].

Apr. 9—President John Braphy, of Central Pennsylvania or No. 2 district of the United Mine Workers of America, protests against the terms of the anti-sedition bill [XV, 836]—The Government files its brief in the Supreme Court of the United States in the case of the United States vs. the Lehigh Coal and Navigation Co. The case revolves around a payment of rebates [XV, 714].

Apr. 10—George N. Peek, on behalf of the Industrial Board of the Department of Commerce, denies that statement of Walker D. Hines, Director General of Railroads, to the effect that the stabilized prices of steel are too high.

Apr. 11—J. L. Lewis, acting president of the United Mine Workers, declares that the miners' organization will take drastic action unless Director General Hines changes his policy in regard to making coal contracts [XV, 773].

Apr. 12—The National Retail Coal Merchants' Association meets at the Fort Pitt hotel in Pittsburgh, Penn., and resolves to seek representation in Government schemes of distribution during reconstruction period and to encourage early buying of coal [XV, 773].

Apr. 13—The workers of the Clinton, Indiana, coal field show their approval of the attitude of the executive board of District No. 11 which protested against a cut in the price of coal to W. D. Hines [XV, 762]—The Victory Loan drive begins at 12 o'clock midnight.

Apr. 15—Director-General Walker D. Hines instructs the individual railroads that they must give all information as to tonnage in coal contracts to the mine workers' officials in the Pittsburgh district—The Jeanesville and Yorktown collieries of the Lehigh Valley Coal Co. start work after an idleness lasting since last February [XV, 774].

Apr. 16—The Miners' Confederation of Great Britain and Ireland meet in conference and approve by a large majority the report of the Sankey Commission [XV, 762]—All of the mines of the Central Coal and Coke Co., at Pittsburg, Kan., are idle, the 1200 miners not reporting for work following the strike order of the district president [XV, 762].

Apr. 17—Back wages under the Sankey award, approximating $25,000,000, are paid out by operators in Great Britain, by order of the Coal Controller, to virtually all of 900,000 workers in the mines of the United Kingdom. The back wages represents an advance of about 25c. per shift worked for employees under 16 and 50c. per shift for employees over 16, applied from Jan. 9, to Apr. 17.

Apr. 18—The strike of the coal workers in the Kansas, Arkansas and Oklahoma fields is extended by Alexander Howat, president of District No. 14, into Missouri. About 6000 men are now involved [XV, 823].

Apr. 19—The New York harbor strike, in its eighth week, is settled under an agreement reached at a meeting presided over by Mayor Hylan, by which the men return to work on a permanent 10- and 12-hr. day basis leaving the increase in wages to be settled by a committee of four representatives of the boat owners and four representatives of the strikers.

Apr. 20—Dr. H. A. Garfield threatens to revoke provision of agreement of November, 1917, unless Howatt orders striking miners of the Central Coal and Coke Company to return to work [XV, 762].

Apr. 22—Representatives of anthracite and bituminous coal producers of Pennsylvania enter protest against any increase in workingmen's compensaion at the second conference on the suggested amendments held at the state capital. Representatives of the miners support the amendment [XV, 835]—The resignation of the members of the Industrial Board, George N. Peek, chairman, is accepted. This action followed the failure of the conference arranged by the board between the representatives of the steel industry and those of the Railroad Administration—The Supreme Court of Pennsylvania decides that where employees of a coal company are sent to a hospital for treatment for injuries, by permission of a company, the latter is responsible for payment of the bills [XV, 884].

Apr. 23—President Wheelwright, of the National Coal Association, appoints a foreign trade committee of seven members to consider the formation of an export association under the Webb-Pomerene law for the coal industry. T. V. Farrell, of the Pocahontas Fuel Co., is chairman of the committee.

Apr. 24—The staff that supported Dr. H. A. Garfield in the work of the Fuel Administration holds a dinner in Dr. Garfield's honor at the Waldorf-Astoria, New York City. Dr. Garfield is presented with a bronze statuette [XV, 868].

Apr. 25—The child-labor provisions of the new revenue bill become effective and will tend to stop the employment of boys under 16 years of age in or about mines in any capacity. Violation of this law will subject the employer's business to a tax of 10 per cent.

Apr. 26—The strike of the 6000 mine workers of the Central Coal and Coke Co. is settled on the agreement that the mining machines and loaders start simultaneously [XV, 917].

Apr. 28—A company of militia is dispatched to Linton, Ind., when the mine workers quit work apparently to aid in an attempt to intimidate certain strike-breaking telephone girls whom the Central Labor Union was said to be planning to deport [XV, 823]—On the initiative of Robert Smillie, president of the Miners' Federation, the Government commission investigating the question of nationalizing the coal mines, subpoenaes seven coal owning peers. The coal owners will be questioned about the income or royalties they derive from their coal properties.

Apr. 29—Several hundred coal miners remain away from work in the Linton, Ind., district, adding to the disturbance started the day before. Federal officials order another company of militia from Bloomington [XV, 917]—A gas explosion in the Regal mine of the Majestic Coal Co., of Alabama, results in the death of 21 employees [XV, 885].

Apr. 30—Proposals looking to a special form for a bill of lading for coal shipments are dismissed by the Interstate Commerce Commission. It is believed that the uniform bills prescribed will be adequate to care for any peculiar requirements of such traffic [XV, 912].

Harrisburg, Penn.

Senator Davis of Lackawanna County has introduced a bill that will provide for the establishment of a Pennsylvania Anthracite Mine Cave Commission modeled after the plan of the Public Service Commission. The commission, consisting of a chairman and three members, at a salary of $5000 annually, to be appointed by the Governor.

The new measure requires every operator to accept or reject at his option the jurisdiction of the commission. If the operator or the corporation accepts, an annual sum equal to 1 per cent. of the gross value of all coal mined during the preceding year must be paid. Making this feature optional on the part of the operator eliminates the coal tax constitutionality question.

Every operator who accepts the jurisdiction of the commission is privileged to make application for permission to mine under streets and structures protected by law, and if the commission determines that no serious damage to life or great public harm will result, permission to mine will be granted, and the operator will not be liable for any penalties under the Davis bill, now in committee, or any act now existing.

The fund raised by the voluntary contribution section will be expended by the commission to pay all damages resulting from mine caves of every nature. This will mean 100 per cent reparation. In certain cases the money can be spent to prevent surface subsidence by erecting artificial support. Any person who is dissatisfied with any order of the commission may appeal to the courts under the same terms as an appeal is taken from the rulings of the Public Service Commission.

The operator, the measure provides, must take some affirmative action in regard to rejecting or accepting the jurisdiction of the commission. If he does not file his rejection in six months he is bound by the act. No new corporation shall be authorized to mine anthracite coal except on its agreement to come within the terms of the act.

The coal companies will be allowed under the provisions of the bill to cave-in the surface if such action does not endanger the lives of the public or cause great public inconvenience.

Uniontown, Penn.

Merchant operators of the Connellsville coke region seem to have reached rock bottom in their curtailment policy, but furnace interests continue to add ovens to the idle list. Five hundred ovens last week were put out of operation by the H. C. Frick Coke Co., but there is no confirmation in coke circles here of the report in the steel trade that the Frick company was contemplating a 60-day suspension of operations. On the contrary, ovens are now being banked for a week instead of being blown out, that fact being taken here to mean that officials are expecting an increased demand for coke at any time and

can more quickly increase production with ovens banked than with them dead. There were no more ovens blown out by the merchant operators during the week.

To what extent the operation of the by-product plant at Clairton has influenced the development of coal tracts in the upper Monongahela Valley is reflected in the report of lockages through lock No. 6 for April, which show that 10,297,000 bushels of coal was shipped down the river. Before the Clairton plant was built the coal traffic from the uper pools was negligible, although it had been developed to a high degree in the fourth and fifth pools. The Carnegie Steel Co. now has five steamers making daily trips to and from the sixth pool. By July 1 the Carnegie company hopes to have a number of other boats added to its fleet, and is said to be contemplating the doubling of river shipments to meet the increasing demands of the byproduct plant.

Inability of coke producers and consumers to reconcile their respective viewpoints as regards price made a sluggish coke market during the week ended May 17, which, however, is still strongly in favor of the producer. Consumers are offering from $3.75 to $3.90 for furnace coke, but producers are balking at anything less than $4. As a result of that condition there is now more than 500 cars of coke standing on track awaiting destination. On the week ended May 10 the region was virtually cleared of loose tonnage by a Pittsburgh steel interest being forced into the open market for its fuel supply by reason of a strike at its mines. The third cargo of foundry coke for South America, gathered in the Connellsville region since April 1, was collected recently and sent to the seaboard for export.

Charleston, W. Va.

For the first time in the last six months production has reached fully 100 per cent. in this territory; this statement is not applicable to the Kanawha district as much as to the New River field which is again being operated to capacity and the mines running steadily each week. That was the condition of affairs on May 15 and there was nothing to indicate that there would be any future slumps. Several factors operated to bring the output up to the capacity of the mines, one source of improvement being a much more fully developed export demand with sufficient ships to meet such orders as New River producers were able to handle; poor shipping facilities having heretofore retarded the shipment of a larger tonnage to foreign markets. Simultaneously with the increased export of coal was a better movement to lake points, although the shipments to such points have been increasing for the last few weeks, or since about April 20. Under such encouraging conditions about 200,000 tons of coal a week is being produced in the New River region. Difficulty has been encountered, however, in getting enough labor to man the mines so as to produce a capacity output, the shortage of miners being in the neighborhood of 25 per cent. This, however, is being overcome to some extent but labor will be scarce, it is predicted, within a short time. The increased demand for smokeless coal has of course had a tendency to make prices firmer and in fact to advance them somewhat, but slack is still selling below former levels and will continue to be sold at such figures until some of the present accumulation is disposed of.

Kanawha mining conditions had undergone a gradual improvement up to May 14, though production was practically at a standstill until the first of the month. Between the dates mentioned however, inquiries became more numerous and lake orders more plentiful; still even up to May 14, it is doubtful if the output of Kanawha mines was in excess of 50 per cent. of normal, mines not being in operation more than three days a week. Mine owners, as a rule, have been waiting to secure better prices before signing contracts. With the general market for coal much better, it is believed they will be able to command higher prices for their coal, and that in the near future they will be getting out coal on a larger scale.

Fairmont, W. Va.

Impetus was given to production in northern West Virginia to such an extent during the first half of the month that by May 15 the output of the mines in the northern part of the state was rapidly approaching capacity. In fact, by the date given, daily shipments had reached over 800 cars a day as against an average of between 500 and 600 cars a day for the latter part of April. Marked gains in the shipment of fuel for railroad consumption were scored during the week ending May 15 as against the first seven days of May. Such shipments constitute nearly a third of the total outgoing tonnage, although there had been quite a substantial growth in lake tonnage during the period above referred to; the total number of cars of coal to the lake from the opening of the lake season to May 8 having been almost 2000 cars. At the same time export shipments were steadily on the increase, as indicated by the growing number of cars going to Curtis Bay, a number of mines having been at work on export orders for the last month. The mines shut down had decreased in number as had the number of unconsigned coal loads on hand. Furthermore the number of cars supplied had dwindled by May 15 from 3000 to 1700 a day; the supply on the date given was still ample for the needs of the district, though it was apparent that a car shortage would develop in the near future.

Canada

Alberta—Judging from the returns showing the amount of coal mined in this province for the first three months of 1919, John T. Stirling, Chief Inspector of Mines for the province, estimates that there will be a decrease in the output for the year of about one million tons. The total production for the first quarter of 1919 was 1,424,683 tons as compared with 1,663,308 tons for the corresponding months of last year. The decrease is distributed generally throughout the province.

Nova Scotia—A bill introduced in the provincial legislature by E. H. Armstrong, Commissioner of Public Works and Mines, dealing with the dispute between Nova Scotia Steel and Coal Co. and the Dominion Coal Co. over submarine coal areas, makes the following provision: After an investigation the Government may make such orders and regulations as may be deemed expedient so that these coal areas may be worked to the best interests of the province. The Government is authorized to turn any area over to another lessee providing compensation is made to the present holder, either in cash or in other areas, or partly in both. This measure is strongly opposed by the Dominion Coal Co. on the ground that its title to its submarine areas is held under legislative sanction. The Dominion company considers that this title should hold as the areas in question contain millions of tons of excellent coal easily mined and suitable for metallurgical use; on the other hand, the areas proposed for exchange have not been proved to contain coal. It is further claimed that the company's security holders are interested and that the property pledged to them would not be changed without their consent.

PENNSYLVANIA

Anthracite

Wilkes-Barre — William Porter and Michael Skurtis were instantly killed on May 9, in the No. 5 colliery of the Lehigh & Wilkes-Barre Coal Co. by a fall of coal and rock.

Gordon—The Barry Coal Co., operating a large washery near this place, is reported to have placed an order for the smaller sizes of anthracite which should keep its plant going for many months.

Honesdale—P. J. McDonnell purchased a culm pile at Marble Hill from the Howard Coal Co., of Scranton, for $50,000. It is estimated that the pile contains 96,700 tons of culm and that it will take two years to remove it.

Hazleton—Charles P. Neill, of the Conciliation Board, ruled that mine workers cannot expect to be reinstated in their jobs when discharged for incompetency. This case was the complaint of H. C. Singley against the Evans Colliery Co., of Beaver Meadow.

Wilkes-Barre—A subsidence of the surface occurred over a portion of the mine workings of the Conlon Coal Co. along Carey Street in Plains on May 12. It caused a weakening of the foundations of St. Paul's convent and the walls supporting a number of private residences in the vicinity.

Scranton—The Scranton Surface Protective Association, through its vigilance committee, is investigating alleged unhealthy conditions caused in the West Park section as a result of mine caves. It is reported that sewer pipes and water mains were broken by recent caves; also that mine cave repairs, by the Delaware, Lackawanna and Western company, were made in a careless way.

More or less serious caves, as the result of mining in the Diamond bed of the Delaware, Lackawanna and Western company, damaged the homes of several families in the 600 block of N. Summer Ave. on the night of May 10. This disturbance is a continuation of settlement of surface which has been occurring in this neighborhood for several weeks. Pillars are being robbed in this section and the coal company is taking precautions on the surface over these workings to safeguard the inhabitants living there.

Pottsville—Representatives of the Philadelphia and Reading Coal and Iron Co. testified before the Lebanon County commissioners, sitting as a board of revision and appeal, that the company's coal land holdings aggregating 4519 acres in Cold Spring Township, Lebanon County, are worth from $35 to $50 per acre. The commissioners recently increased the assessed valuation of the land to $140,000,000.

Harrisburg—The bill drafted by the attorney general requiring self-insurers under the Compensation Act to pay a state license of two per cent. based on pay roll, was presented in the House on May, by Mr. Ramsey, chairman of the Mines and Mining committee. The bill is a duplicate of that introduced in the Senate. It is designed to furnish funds to operate the Compensation Bureau. The House passed on third reading the bill making the lawful ton of anthracite coal 2000 lb.; it now goes to the Senate.

The Supreme Court, in an opinion rendered in the case of Mrs. Bridget Clark, of Parsons, against the Lehigh Valley Coal Co., reversed the decision of the lower courts and the Compensation Board, and sustained the decision of the Referee, George Beemer, in awarding the widow $2500. There was a question of whether his death was due to natural causes, or from causes other than in the course of his employment, or if it was due to the noxious gases in the mine, causing vomiting and resulting in the rupture of a blood vessel.

Luzerne—The Carnegie Hero Fund Commission in its report for this year makes two awards for local acts of heroism which took place in 1917. An explosion occurred at the Hillman colliery of the Wilkes-Barre Anthracite Coal Co., at which time Leroy Winters was killed, David A. Cadwalder met his death in an effort to save Winters and John Harry made a vain attempt to rescue the men who died.

The commission awarded a bronze medal to the widow of Cadwalder, and also $10 a month with $5 additional for each of her five children while they are dependent upon her and not over 16 years of age. John Harry was awarded a bronze medal and $1000.

Bituminous

Russellton—The Republic Collieries Co. of this place, is making a number of improvements at its No. 2 mine, at a total cost of $300,000. The shaft is being enlarged and lined with concrete, and the wooden tipple is to be replaced by a steel structure. Frank Foye, of Brownsville, Penn., has the contract work.

Patten—The Barnes Coal Co., has a large crew of men clearing the land near their operations in the vicinity of this place. They are preparing a suitable site for the erection of 50 houses, two of which are completed. The foundations for ten have been laid and as soon as the land is in shape the others will be commenced. The houses are of brick construction and the greater number will be of the bungalow type.

Altoona—A. L. Anderson & Bros., Inc., Altoona contractors, have the construction of a 3900-ft. siding for the Cambria and Indiana Railroad Company. This branch line is to run to the new mine of the Commercial Coal Mining Co., at Red Mill, Blacklick Township, Cambria County. The coal company is preparing to develop the property by means of a slope, work on which was started by Foye Bros., of Ebensburg.

Uniontown—Stockholders of the Orient Coke Co. held their annual meeting in this place, elected officers and directors and in-

spected the company's plant in Redstone Township. R. M. Fry was re-elected general manager for the sixth consecutive year. The officers and directors re-elected were Julian Kennedy, Pittsburgh, president; Robert Bentley, Youngstown, Ohio, first vice president; J. W. Kennedy, Pittsburgh, second vice president; J. O. Miller, Pittsburgh, secretary-treasurer; R. M. Fry, Uniontown, general manager. Other directors elected were Julian Kennedy, Jr., and David Davis, Pittsburgh.

Johnstown—A number of local men are interested in the Sandford Coal Co. of which John C. Cosgrove is a prominent stockholder. This new firm is having a steel tipple erected and modern mining mechinery installed. Developments are being pushed rapidly, a shaft was sunk to coal recently and the mine is being opened up in the seven-foot seam of coal here. Electric equipment is being installed. Mr. Cosgrove is interested in other plants in this field; one mine is producing 2000 tons daily. The field controlled by Cosgrove and Co. consists of 8000 acres of high-grade seven-foot coal.

WEST VIRGINIA

Holden—A new tipple at the No. 2 mine of the Island Creek Coal Co. at this place will be erected at once to take the place of the old tipple which was destroyed by fire about the first of May. The fire damage was $50,000.

Bluefield—The Glen Alum Fuel Co.'s store together with its contents were completely destroyed by fire on the night of May 12. The loss is stated to be $60,000 partly covered by insurance. The origin of the fire is unknown.

Philippi—The large tipple of the Consolidation Coal Co. at Berryburg, Barbour County, was entirely destroyed by fire on the night of Wednesday, May 7, the loss being estimated at $40,000. As soon as practicable another structure was begun and a temporary structure was utilized for loading coal.

Clarksburg—Fire destroyed the tipple at the plant of the Southern Coal and Transportation Co., at Berryburg on May 9, entailing a loss of $20,000. It is believed to have been the work of incendiaries and officers are investigating the matter.

A deed in the county clerk's office states that the Corona Coal Co., successors to the Commercial Coal and Coke Co., purchased the Reynolds estate from Floraneus, for $20,000. This tract is at Hepzibah and contains approximately 100 acres.

Hinton—Development of the coal resources of Greenbrier County, heretofore almost untouched, is indicated by the prospecting under way at the present time and by the purchase being made of coal land in that county with a view to future development, the Canden Coal Land Co. just having purchased a large acreage near Rupert. More extensive development has been prevented because coal lands were inaccessible but it is believed that additional railroads will soon stimulate greater mining activities in Greenbrier County.

Fairmont—The following officers were elected at a meeting of the Northern West Virginia Coal Operator's Association on May 9: C. H. Jenkins, treasurer of the Hutchinson Coal Co., was re-elected president; he was the first president of this association. George T. Bell, executive vice-president, was chosen secretary. A. Lisle White, of Clarksburg was elected treasurer, succeeding C. J. Ryan of Hepzibah.

The West Virginia State Department of Mines held an examination for mine foremen at this place on May 13. The chief of the department, W. J. Heatherman, took personal charge of matters. The preliminary examination consisted chiefly of questions relative to the minings laws of the state; next the map work was taken up, the ventilation of mines being traced on blueprints; a third session completed the mine foremen's examination. An examination for fire bosses was also held, dealing at length with the gaseous condition of mines.

The subject of railroad fuel is a live one all over the country because of its magnitude and especially so in the Fairmont region because it is a substantial part of the business here. Accordingly the Northern West Virginia Coal Operators' Association, on May 9, decided not only to ask the Baltimore and Ohio Railroad Company to furnish figures on the railroad fuel loaded on that road, but also to secure the same information on other roads. This association represents coal operations aggregating 80 per cent. of the tonnage of northern West Virginia, or 20,000,000 tons annually.

Huntington—At a meeting of the West Virginia Coal Association held in this city on May 13 the selection of C. H. Jenkins of Fairmont and Quinn Morton, of Charleston, as directors of the National Coal Association was confirmed and Jarius Collins was indorsed for director at large for West Virginia. The holdover directors are T. B. Davis of Holden and John J. Tierney of Powhatan. J. G. Bradley of Dundon, president of the association, was elected as chairman of the delegation which is to attend the National Coal Association meeting. The executive committee of the association went on record as opposing the contemplated order of the Railroad Administration prohibiting the shipment of West Virginia coal for railroad use north of the Ohio River and sent a vigorous protest to Washington.

In the week ending May 10 substantial progress was made in the Logan field of West Virginia in the effort of the mines there to get back to normal production, the output being 23,000 tons in excess of the week ending May 3. The total production in this field was 161,000 tons, or 52 per cent. of full time capacity, and only about 40,000 tons less than the production for the corresponding period of 1918. Production losses were further reduced, being for the week above given only 140,000 tons, with 131,000 tons as the no market loss, a decline of 13,000 tons in that respect, losses from car shortage, labor shortage and mine disability cutting little or no figure. It has been largerly through additional lake orders that the mines of the district have been able to forge ahead, though coal from the district is being marketed generally in the West. During April the total production of the district was 572,000 tons or about 40 per cent. of normal. In April, 1918, 886,000 tons were produced.

Charleston—A score of mines on the Kanawha, Glen Jean & Eastern branch and the White Oak branch of the Chesapeake & Ohio railroad whose coal was transported over this road during the war will ship all in the future via the Virginian Railway. Half a dozen mines on the Stone Coal branch of the Virginian will at the same time be reached by the Chesapeake & Ohio hereafter, although served by the Virginian Railway during the war.

The organization in this city of the Black Band Consolidated Coal Co., with a total capitalization of $2,000,000, means not only a continuation of mining operations at Olcott, where the Black Band Fuel Co. formerly operated, but it means as well further development of the property in question embracing about 5000 acres of coal land. There are four mines on this property which will be operated as soon as certain improvements are made. Incorporators of the new company include S. B. Avis, I. C. Jordan, and N. F. Young, all of Charleston; Wm. Freudenburger and Henry A. Jones of Pitsburgh, Penn.

Accidents of a fatal nature in the mines of West Virginia in April were less in number than for March, there being 14 deaths in April and 18 in March. Nine of the 14 deaths were from the usual cause—falling roof and coal. The only other death inside the mines was caused by a mine car. Mine cars were responsible for three and a motor for one fatal accident on the outside of the mines. There were three nonfatal accidents each in McDowell and Kanawha; Boone, Braxton, Fayette, Logan, Marion, Mercer, Mingo and Ohio each had one accident. A special effort is being made by the Department of Mines to reduce mine accidents to a minimum, the head of the department having issued specific instructions to guard against dust accumulations in the mines by providing additional doors where necessary.

Following the creating of four additional mine inspection district in West Virginia, it became necessary to rearrange the boundary lines of the existing districts. As so arranged the various districts are now constituted as follows:

First District—Barbour in part, Grant, Mineral, Preston, Tucker and Randolph in part.

Second District—Barbour in part, Harrison in part, Lewis, Marion in part, Preston in part, Randolph in part, Taylor and Upshur.

Third District—A part of Harrison and a part of Marion.

Fourth District—Marion in part, Monongalia and a part of Preston.

Fifth District—Harrison in part and Marion in part.

Sixth District—Brooke, Harrison in part, Marshall, Ohio and Wetzel.

Seventh District—Boone in part, Braxton, Clay, Gilmer, Greenbrier in part, Kanawha in part, Lincoln in part, Logan in part, Nicholas in part and Webster.

Eighth District—Kanawha in part, Logan in part, Mason and Putnam counties.

Ninth District—Fayette in part, Kanawha in part and Wyoming in part.

Tenth District—Boone in part, a part of Kanawha and a portion of Raleigh County.

Eleventh District—A portion of Fayette, a part of Kanawha and a part of Nicholas County.

Twelfth District—A part of Fayette, a part of Greenbrier, a part of Nicholas, a part of Raleigh and Summers Counties.

Thirteenth District—A part of Fayette and a part of Raleigh County.

Fourteenth District—A part of Raleigh and a part of Wyoming County.

Fifteenth District—A part of McDowell, all of Mercer and a part of Wyoming County.

Sixteenth District—A part of McDowell and a part of Wayne County.

Seventeenth District—A part of McDowell, all of Mingo, and a part of Wayne.

Eighteenth District—A part of McDowell.

Nineteenth District—Lincoln in part and Logan in part.

OHIO

Leetonia—While at work in the Delmore coal mine near this place, Daniel Dempsey sustained injuries from a fall of rock. He died while being taken to the city hospital at Salem.

Cambridge—Joe Kotch, employed as a miner in the Harryette mine of the National Coal Co., was instantly killed by a fall of coal.

Columbus—A meeting of the Southern Ohio Coal Exchange was held in Columbus recently to name delegates for the Chicago convention of the National Coal Association, which will be held in the Windy City, May 21 to 23 inclusive. Much interest centers in the coming meeting of the National Coal Association.

Nelsonville—The Sunday Creek Coal Co., is installing a coal crusher at the Jobe mine near here which will be ready for operation within a short time. The crusher has a capacity of 1000 tons daily and will be used to prepare coal for several railroad contracts covering mechanical-stokers fuel. The machine is a Jeffrey crusher of the latest type.

ILLINOIS

New Douglas—The Madison County Mining Company struck a fine 7½-ft. seam of coal near this place in Madison county, on the Toledo, St. Louis & Western Railroad. It is believed that the seam is the same as that at Sorento, in Bond County.

Duquoin—The new coal crusher which the Victory Collieries Co., of Tamaroa, north of here, is installing at their plant is rapidly nearing completion and will improve output.

An explosion at the Marion County Coal Company's mine at Glenridge, near Centralia, occurred May 12, killing four men. The men—John Dicercon, Henry Cooley, Bux Burgess and Robert Thompson—were shot firers in the mine and a windy-shot was the cause of the accident. The fact that it happened at 5:25 in the evening probably saved many more lives as these four men were the only ones in the mine at the time. Mine Rescue teams from Duquoin, Benton and other southern Illinois towns were immediately called and with their combined efforts all of the four bodies were taken out within 36 hours. The fire which was caused by the explosion has not yet been extinguished.

Belleville—The St. Louis & O'Fallon Coal Co. has reported to the police of this vicinity that brasses to the value of $200 were stolen from the so-called Nigger Hollow mine a few nights ago. It is said that the thief came to the mine with a wagon, loaded up the brasses and then drove away. The mine announced that a reward of $100 would be paid for the arrest of the thief.

East St. Louis—State Mine Inspector Harry Thompson of this place recently visited southern Illinois for the purpose of reviving mine rescue teams throughout the district. Special interest is being shown along this line because of the coming meeting at Springfield, Ill., in September, when all the teams will compete against each other. A movement is on foot to offer as prizes to the winning teams, a free trip to the dedication of the new Bureau of Mines building which is to be held at Pittsburgh, Penn., about October 1.

West Frankfort—Judgment has been given A. Sedden against the Old Ben Coal Corporation for $25,000 on account of damages to Sedden's property, coming from a subsidence of the surface. There are twenty-two cases of this kind on the city court docket. The plaintiffs contend that the coal company is violating the state law in not leaving sufficient pillarage after the coal has been removed. Many residence property owners along East Oak Street and East Elm Street in the southeastern part of the city say they have suffered heavy damages from this cause and after the filing of the several suits for damages the Sedden case was tried as a test case.

Personals

C. H. Ronland resigned, on May 14, his position as superintendent of the Upper Lehigh and Hazle Brook collieries of the J. S. Wentz Co. **L. W. Muir** has been appointed superintendent at Upper Lehigh and **E. P. Humphrey** at Hazle Brook.

A. A. Layne has been appointed as assistant general manager to the following coal companies: Logansport Coal Co.; Pittsburgh and Allegheny Coal Co.; Pittsburgh and Clarion Coal Co.; and the Pittsburgh and Cambria Coal Co.

F. X. Meehan has recently been appointed advertising manager of the Walter A. Zelnicker Supply Co., of St. Louis, Mo. Mr. Meehan has had a broad experience in various executive capacities with a number of well known firms.

Roland B. Page has recently been appointed eastern district manager for Leamay **Company, the** manufacturer centrifugal pumping machinery. His offices are at 810 Broad Exchange Building, Broad and Franklin Streets, Boston, Mass.

Carl Becker, who previous to entering the service was with the Union Colliery Co., at Cambridge, Ohio, and Duquoin, Ill., has recently received an honorable discharge from the army and has taken a position in the St. Louis office of the Peabody Coal Co.

C. H. Jenkins, treasurer of the Hutchinson Coal Co. was the unanimous choice of the directors of the Northern West Virginia Coal Operators' Association as a member of the board of directors of the National Coal Association to represent the former Association.

W. P. Engleman has been retained as chief engineer of the Domestic Coke Corporation, of Fairmont, W. Va. During the war Mr. Engleman was in the service of the Government as a coke and byproduct expert; he has resigned his government position and has established his headquarters in Fairmont.

A. E. Hitchner has been appointed manager of the mining section of the industrial sales department of the Westinghouse Electric & Manufacturing Co. with headquarters at East Pittsburgh, Penn. Mr. Hitchner joined the Westinghouse sales organization as industrial salesman in their Philadelphia office in 1909. In 1912 he was sales representative in charge of the Wilkes-Barre office of the company.

S. G. Pierson, formerly vice president and general purchasing agent of the Colorado Fuel and Iron Co., recently has been made vice president and treasurer. **J. B. Marks,** formerly assistant to Mr. Pierson, was promoted to the position of purchasing agent. **D. A. Stout,** chief engineer of the fuel department, has been appointed assistant manager of that department, taking the place of **B. J. Matteson,** recently made the president's chief industrial representative. Mr. Stout will also continue as chief engineer.

Obituary

Jasper A. Writer, secretary and treasurer of the Colorado Fuel and Iron Co., and for more than 37 years in the company's service, died Mar. 19, 1919. Mr. Writer was 61 years old. He began work for the company in 1881; in 1892 he was made general auditor, in 1912 secretary and later secretary-treasurer.

Alva Tompkins, one of Pittston, Penn.'s, early settlers and a pioneer of the anthracite coal industry, died at his home in Tunkhannock, on May 14. He was 92 years of age. Mr. Tompkins was prominently connected with the mining and shipping of coal during its early development period. He was in the coal business for 34 years, starting in 1851. Mr. Tompkins owned the second breaker built in the anthracite region and shipped coal for eight years prior to the building of this structure. He held a controlling interest in a number of coal companies operating at present; he was also interested in a number of banks and was connected with educational institutions.

Coming Meetings

American Wholesale Coal Association will meet on June 3 at Cleveland, Ohio. Secretary, L. Romanski, Chicago, Ill.

Illinois and Wisconsin Retail Coal Dealers' Association will meet at Hotel Nelson, Rockford, Ill., June 4 and 5. Secretary, I. L. Runyan, Chicago, Ill.

Southwestern Interstate Coal Operators' Association will hold its annual meeting June 10 in the Keith and Perry Building, Kansas City, Mo. Secretary, C. N. Fish, Leavenworth, Kan.

American Society of Civil Engineers will hold its forty-ninth annual convention in St. Paul and Minneapolis, Minn., June 17 to 20. Secretary, C. W. Hunt, 33 West 39th St., New York City.

Mine Inspectors' Institute of the United States of America will hold its annual meeting July 8 to 11 at Indianapolis, Ind. Secretary, J. W. Paul, Pittsburgh, Penn.

Kentucky Mining Institute will hold its annual meeting June 6-7 at Lexington, Ky. Secretary, C. W. Strickland, Huntington, W. Va.

American Institute of Mining and Metallurgical Engineers will hold its fall meeting Sept. 22 to 26 in Chicago, Ill. Chairman Chicago meeting, Carl Scholz, 547 West Jackson Boulevard, Chicago, Ill.

American Society of Mechanical Engineers will hold its spring meeting at the Hotel Statler, Detroit, Mich., June 16 to 19. Secretary, Calvin W. Rice, 29 West 39th Street, New York City

American Institute of Electrical Engineers will hold its annual convention at the Lake Placid Club, Adirondacks, N. Y., June 24 to 27. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

Northeast Kentucky Welfare and First Aid Association will hold a first-aid contest July 4 at Pikeville, Ky. Secretary, E. H. Sowards, Pikeville, Ky.

The Rocky Mountain Coal Mining Institute will meet in Salt Lake City the first week in July, 1919. Secretary, F. W. Whiteside, Denver, Colo.

West Virginia Coal Mining Institute will hold its semi-annual meeting June 3 and 4 at the Frederick Hotel, Huntington, West Virginia. Secretary, Karl F. Schoew, Huntington, West Virginia.

Industrial News

Ashland, Ky.—The Green Rock Coal Co. has filed notice of an increase in its capital from $25,000 to $50,000, for expansion.

Williamsburg, Ohio—The Polley Coal Co., has been chartered with a capital of $25,000 by James Sheehy, U. S. Siler, John R. Howard and B. E. Sheehy.

Memphis, Tenn.—The Memphis Coal Co. has filed notice with the secretary of state of an increase in capital from $60,000 to $100,000, to provide for general expansion.

Bunceton, Mo.—A. H. Pearson and associates are understood to be having plans prepared for the early development of cannel coal properties located in Cooper County.

Hazard, Ky.—The Kentucky River Coal Mining Co. has filed notice with the secretary of state of an increase in its capitalization from $150,000 to $250,000, to provide for expansion.

Coalfield, Tenn.—The Coalfield Coal Co. is understood to be arranging plans for the rebuilding of the electric power plant at its properties recently destroyed by fire, with loss estimated at $5000.

Bristol, Va.—The Floyd-Elkhorn Consolidated Collieries have filed notice with the Secretary of State of an increase in their capitalization to $315,000, to provide for general business expansion.

Memphis, Tenn.—The Turner & Turner Coke and Fuel Co. has been incorporated with a capital of $50,000 to engage in the production of coke and other fuels. G. S. and L. E. Turner are the principal incorporators.

Ashford, W. Va.—The Curtis Branch Coal Co. has been incorporated with a capital of $25,000 to engage in general coal mining in the Ashford district. E. E. Huddleston, Charleston, is the principal incorporator.

Whitesburg, Ky. — Samuel Collins, Whitesburg, and associates, have completed negotiations for the leasing of extensive coal properties in the vicinity of Sergent, Ky., and are understood to be arranging for early development.

Barbourville, Ky.—The Kentucky Velvet Coal Co. has been incorporated with a capital of $150,000 to engage in general coal mining operations in the vicinity of Barbourville. C. C. Smith, W. B. and Walter Riley are the incorporators.

Buckhannon, W. Va.—The West Virginia & Pennsylvania Coal and Coke Co. has been incorporated with a capital of $50,000 to engage in general coal mining operations, etc., in the vicinity of Buckhannon. A. M. Minerd and O. B. Talbot are the principal incorporators.

Charleston, W. Va.—The Siler Coal and Land Co., recently organized with a capital of $150,000, is understood to be planning for the commencement at an early date of the development of a total of 15,000 acres of coal properties recently acquired. T. E. Siler is the principal incorporator.

Charleston, W. Va.—The Black Band Coal Co. has been incorporated with a capital of $2,000,000 to engage in coal mining operations in West Virginia. N. F. Young, S. B. Avis, I. C. Jordan and William Freudenburger, Charleston; and Henry A. Jones, Pittsburgh, Penn., are the incorporators.

Columbus, Ohio—The Pennsylvania lines announce fuel contracts for more than 2,500,000 tons. Several Hocking operators will share in on these contracts. The George M. Jones Co., secured 572,000 tons and the Elk Coal Co., 114,000 tons. The average price was around $2, for mine-run.

Dora, Ala.—The Mary Lee Coal Co., recently incorporated with a capital of $15,000, has perfected its organization plans, and is arranging for the commencement of work at an early date on the development of about 160 acres of coal properties. It is planned to have a capacity of about 200 tons daily. J. Johnson is president.

Paintsville, Ky.—The Wells-Elkhorn Coal Co., recently organized, is planning for the installation of new mining machinery and equipment in three mines, including motors and auxiliary appartaus. It is understood that the company is arranging for the construction of a power plant for works operation. C. O. Messenger is general manager.

Chattanooga, Tenn.—The Suck Creek Coal Co., recently organized with a capital of $350,000, is arranging for the early development of approximately 25,000 acres of coal properties in the Chattanooga district. The company has acquired the mines of the Montake Coal Co. for operation. G. F. Mehan is president; Z. C. Patten, vice-president; and C. L. Hall, general manager.

Chicago—With war orders, high prices and careful management the O'Gara Coal Co. which failed in 1912 is now solvent. This fact became known in the federal court when Judge Carpenter allowed all claims of creditors, except one for $1,500,000 by Thomas J. O'Gara, former head of the company, presented as the value of property turned over by him to the receiver.

Louisville, Ky.—The Illinois Central R.R., has requested the Louisville District Freight Traffic Committee for a revision of rates on coal from mines in Western Kentucy to Paducah, Fulton, Mayfield and intermediate points, asking the removal of preferential rates on nut, slack and pea coal, and for the placing of western Kentucky and Southern Illinois on a parity. The Southern R. R. has asked for a 10 cent per ton advance from mines on its Tennessee lines also Kentucky and Virginia lines to sations on the Elkin & Allegheny Ry. in North Carolina.

New York, N. Y.—The coal trade in the last four Liberty and Victory Loan campaigns subscribed a total of $62,510,450, to which should be added a liberal subscription for the First Liberty Loan, but which was not credited to the industry as such. In addition the local trade contributed $119,937.75 to the Red Cross and $188,572.49 to the War Work campaign. The trade feels that its record in this respect is worthy of commendation and those who have been in charge of the campaigns, particularly Michael F. Burns, John E. Berwind, Richard H. Williams and LeBaron S. Willard take the occasion to congratulate their associates upon the showing which has been made.

Weekly Review

Demand for Hard and Soft Coal Growing Better—Production Figures Show an Increase in Output—Indications Point to a Serious Labor and Car Shortage in the Fall—Bituminous To Be Scarce Before Long—Anthracite Mines Busy

THAT the demand for both anthracite and bituminous coal is increasing from week to week is proved by the gradual betterment in the output of the two kinds of fuel. During the week ended May 10 (the latest complete statistics available) there were produced 8,430,000 net tons of bituminous and 1,759,000 net tons of anthracite, as against 8,015,000 net tons of the former and 1,695,000 net tons of the latter in the week ended May 3.

Many large consumers of soft coal are still buying only for current requirements, in the belief that they will be able to contract for larger tonnages at any time. But this policy, to say the least, is an evidence only of shortsightedness on the part of those who pursue it. Based on present conditions, it requires no vivid imagination to foresee a coal scarcity next winter every bit as serious as that which the country experienced a year ago. There are several good reasons for this statement.

First, there is going to be a labor shortage. Not only has no new labor come into the United States for some time, but there has been a general exodus of foreign labor from our shores. More laboring men are returning to the countries of their origin than ever before in our history. This condition already is making its effect felt on the coal industry. One corporation operating a number of mines in Southern Illinois lost 583 men within a period of two weeks. Another company, operating mines in the East, has suffered a still greater loss covering a period of three months. An investigation conducted in the Hazard coal fields of Eastern Kentucky, where the mines are shipping large quantities of soft coal to the lakes, discloses that not an operation in that whole region has enough men. The result is that the mines are unable to produce anywhere near the tonnage reasonably expected of them.

This state of affairs promises to grow worse instead of better, for many mine workers, rather than wait until an improvement sets in to give them more regular employment, are leaving for more favored industries.

There is every reason to believe that there will be a serious car shortage next winter. Cars are plentiful at this time, it is true, but that is only because there is little demand for fuel. Let the demand become more pressing, and immediately it will be common knowledge that though the railroads have been discarding old and worn-out coal carrying equipment, they have not been adding new equipment to take its place. Our grain crop this year will be the largest we have ever harvested. Most of it will go abroad to feed starving Europe. The railroads will have to haul this grain to seaboard; and while they are hauling grain they cannot haul coal. At that very time, in the fall, the demand for fuel will be at its height. The result is obvious.

Conditions a few months hence are being discounted by bituminous operators, for many of them are growing distinctly conservative on contracts that call for deliveries through to next April. Sales agents are being warned to take care only of regular customers.

There is a quiet but steady inquiry for the better grades of soft coal, and prices are being maintained. The railroads are buying heavily, at prices ranging from $2.10 to $2.50, according to the district from which the coal is obtained. However, there are several large shippers who are still seeking May and June orders. There are sections, as in the Fairmont field of West Virginia, where there are plenty of miners but a great lack of spot business. For this reason operators in that field are quoting coal at prices lower than rule elsewhere; but even then the tonnage is disposed of with great difficulty.

The demand for the domestic sizes of anthracite continues strong from every quarter. There is a steady call from Canada, the West, and particularly from New England. The mines are operating to maximum capacity to meet the demand, and are doing their utmost to make up for the loss in production suffered the first four months of this year.

WEEKLY COAL PRODUCTION

The improvement in the production of bituminous coal which was recorded during the week ended May 3 continued through the week of May 10, the output during which is estimated at 8,430,000 net tons as compared with 8,015,000 net tons during the week of May 3 and 7,378,000 net tons during the week ended Apr. 26. During the same week of last year improvement also occurred when compared with the week of May 4, 1918, but such improvement failed to equal that of the current week. The daily average per working day is estimated at 1,405,000 net tons, and for the first time in a number of months exceeds the daily average for the calendar year to date, estimated at 1,359,000 net tons. For the period Jan. 1 to May 10 the production of bituminous coal is estimated at 152,218,000 net tons, and falls approximately 25 per cent below the output during the same period of last year, estimated at 201,023,000 net tons.

As in the case of bituminous production, improvement was also recorded in the anthracite field during the week ended May 10, the production being estimated at 1,759,000 net tons. The daily average during the week ended May 10 is estimated at 293,000,000 net tons, and while considerably below the daily average during the corresponding week of 1918, estimated at 334,000 net tons, it is far in excess of the daily average for the calendar year to date, estimated at 242,000 net tons.

Shipments of bituminous coal to all points from tidewater harbors during the week ended May 10 are estimated at 328,257 net tons, as against 397,174 net tons during the week preceding. Decreases during the current week occurred at all harbors with the exception of Philadelphia. The greatest decrease occurred at New York, the tonnage loaded declining to 178,250 net tons as against 235,141 net tons during the week ended May 3.

The tidewater shipments to New England during the week ended May 10 amounted to 72,409 net tons, which was a slight decrease compared with the tonnage moved during the week preceding, 84,176 net tons. Hampton Roads was the lone harbor to show improvement during the week, while shipments from New York decreased approximately 8400 net tons, or 20 per cent.

The production of beehive coke in the United States during the week ended May 10 is estimated at 261,115 net tons, as compared with 298,893 net tons during the week preceding and 623,993 net tons during the week ended May 11, 1918. Decreases in production occurred in Pennsylvania, West Virginia, Washington and Utah, while in other states the production was slightly in excess of that reported during the week ended May 3. For the calendar year to date the production of beehive coke amounted to 7,762,124 net tons as compared with 10,710,344 net tons during the same period of 1918. The daily average during the current week is estimated at 43,519 net tons as against 69,294 net tons during the calendar year to date, and 95,628 net tons for the same period of last year.

The bituminous coal dumpings at the lower lake ports during the week ended May 3 are estimated at 589,790 net tons as against 628,215 net tons during the week ended May 4, 1918. For the season to date, however, the dumping, estimated at 1,502,482 net tons, exceeds that for the same period of last year by approximately 180,000 net tons, or 15 per cent.

BUSINESS OPINIONS

The Iron Age—There is no mistaking the better feeling in the market following the dissolution of the Industrial Board and the freeing of the price situation from Government muddling. As at the original announcement of the March 21 prices, this last development has brought the release of some business held up for several weeks. That railroad buying before the end of the year will be on a considerable scale is more confidently looked for, as largely increased appropriations are discussed.

American Wool and Cotton Reporter—Fine wools are strong and low wools are coming in for a little attention at the present time. Prices are very firm with an advancing tendency. At the Cape, the United States, England and France have been buying rather heavily, and a large proportion of the wool has already been sold. Staple cotton is especially in demand, but is hard to obtain. Short cotton is in little demand at present. Mills are feeling much more optimistic on future business.

Marshall Field & Co.—Current wholesale distribution of dry goods is in excess of the corresponding week of 1918. Retail merchants continue to visit the market frequently and in greater numbers. All report excellent business. Orders from road salesmen, for both immediate and future delivery are in much greater volume, equaling any previous record. The market remains firm with retailers buying freely for fall. Some lines have been sold out. Collections are excellent.

Atlantic Seaboard

BOSTON

Slow movement of bituminous. Railroad buying leaves large tonnage yet unplaced. Operators conservative as to contracts. Spot orders still sought. More confidence shown in future business. Navy bids awaited with much interest. Better outlook for export. Little inquiry for Hampton Roads coals. Anthracite in demand from every quarter. Noticeable decrease in tidewater shipments by several companies. Retail trade brisk.

Bituminous—Receipts are on the same light basis that has been characteristic this season. The movement continues slow, and only through diligent canvassing is new business being developed. Many buyers are still "trying coals," the current market lending itself admirably to that method of delaying purchases. There are a good many steam-users in this territory who are buying from month to month on the theory that contract propositions will remain open until spot prices begin to swing upward, but manifestly there are pitfalls in any such policy. Admittedly, much of the present light output in all the regions is due very largely to lack of orders, but from week to week it is becoming increasingly apparent that were the orders in hand there would not be a sufficient supply of labor to get the coal.

So far as New England is concerned, no more railroad buying is anticipated this season. Although it is the policy of the Railroad Administration to publish the successful bids, there has been a good deal of secretiveness over the purchases made by certain of the roads in this territory. It is understood, however, that the range of price was about the same in every case, namely from $2.35 @ $2.55 f.o.b. mines per net ton; but aside from limited tonpages of high-grade gas coals for special runs, the average of quality would appear to be well below the customary mark. Many large shippers who have been customary channels of supply to the New England railroads this year are without a ton of locomotive business, and a large tonnage is left unplaced when comparison is made with other years. Of course, the roads here are buying something like a round million tons less than in 1917-1918, or nearly 15 per cent., but there is much interest in the trade to see what attitude certain of the large shippers will now take toward both spot and contract business.

It becomes increasingly clear that the producers in central Pennsylvania are growing distinctly conservative as to contracts that call for deliveries through to next April. Contract figures thus far have been on the basis of a dull market through the season, but certain interests who have the reputation of being far-sighted are warning their sales agents to take care only of regular customers. Buyers here are proverbially slow in sensing such a situation, and this may be another year when some of the larger consumers find themselves with increased business and without adequate provision for fuel supply. The activity of oil distributors has some bearing on this situation.

On the other hand, there are several important shippers who are still seeking May and June orders. There are sections, as in Fairmont, where there are plenty of miners, but a great lack of spot business. For this reason there are strong selling efforts at prices down to the railroad level and below, although the tonnage is absorbed only with great difficulty. There are frequent cases of "padding" on contracts, and consignees are complaining at the way their storage has been stuffed since Apr. 1. We know of plants where three to four months quota has already been received. Unless the production drops seriously below the present level, it is hard to see how there can be any broad market in New England until fall, unless the boom in general business comes earlier than is now looked for.

That a prosperous upturn is due some time between now and next spring is the way many people are talking. With the soldiers back, and peace conditions in the way of being restored in Europe, there is no doubt that commerce will improve rapidly. There are tremendous quantities of supplies that Europe will need from us, and it would seem that coal men are within bounds when they argue that coal will be very much in demand by October or November. Interests here are not quite so optimistic, but if the country is to have a prosperous wave it is probable that New England will get its share. Without doubt there is a lot more confidence in futures than was the case sixty days ago.

Meanwhile, there is only light buying of Pocahontas and New River in this market. The financial statement for April of the New England Fuel and Transportation Co. and related companies showed the extent to which the rehandling business has fallen off. It is the exception when an inland consumer takes his coal from tidewater; the great bulk of the tonnage is being supplied all-rail. Some expensive plants are practically idle, and overhead charges this year will reach record figures. Coastwise freights are easy; charters can be made at $1.50, Hampton Roads to Providence, and no takers. Were better dispatch to be had at New York piers, it is probable that a large number of soft coal barges would be diverted to the Long Island Sound trade.

Current quotations on bituminous at wholesale are about as follows:

	Clearfields	Cambrias and Somersets
F.o.b. mines, net tons	$2.15@2.75	$2.75@3.25
F.o.b. Philadelphia, gross tons	4.27@4.95	4.95@5.50
F.o.b. New York, gross tons	4.62@5.29	5.29@5.85
Alongside Boston (water coal), gross tons	6.10@6.85	6.90@7.55

Georges Creek is quoted at $3.20 per net ton f.o.b. mines.

Pocahontas and New River are being quoted at $4.69@5.14 per gross ton f.o.b Norfolk and Newport News, Va. Alongside Boston the same grades are being offered at a range of from $6.89@7.24, and on cars Boston and Providence at from $7.60@7.90 per gross ton, the latter being the contract price f.o.b cars for season delivery.

Anthracite—The domestic sizes are in strong demand from every quarter. New England is no exception in this respect, and all the shippers find it hard to regulate the flow of coal in such way as to provide for the really urgent cases. The cool weather this spring and the comprehensive advertising indulged in throughout the country have combined to bring the public into the retail market to a greater extent probably since the years when strikes were threatened. Receipts both by rail and water are disappointing to all the retail dealers, for they are anxious to put out coal while consumers are eager to take it. In cities like Providence, New Bedford and Boston the retail demand has been unprecedented in the spring months. There are several cases where dealers have actually delivered in April from one-fifth to one-sixth of their normal tonnage for the year. Orders are still pouring in, and the average householder is not at all inclined to wait. He has the money to pay, and if he can't be served by one dealer he will try another.

To a notable extent some of the smaller distributors of anthracite at New York show a disposition to favor their all-rail business rather to the disadvantage of customers who take their coal by water. Heavy car demurrage, complaints of the lack of screening at the piers, and the bill of expense for operating barge lines are reasons enough for this attitude. In some cases dealers have been notified that they cannot look to their customary sources for the usual tonnage, and it all has a serious bearing on the volume of coal for New England. Opinions seem to differ whether there will be a quiet period in the summer, or whether this present extraordinary demand will be continuous.

NEW YORK

Domestic coals in heavy demand, with stove leading. Householders getting ready for vacations insist upon deliveries. Operators are doing their best to overcome deficit. Line dealers taking coal. Bituminous tidewater market slow, but all-rail trade is active. Brisk market anticipated within next few weeks. Manufacturers entering the market for the better coals.

Anthracite—With nearly every consumer anxious to get his coal for next winter into the bin, the demand for the various domestic sizes of anthracite continues. Stove coal appears to be the favorite. This is due to the preparation accorded egg and chestnut last year, when the trade heard many complaints regarding poor coal. While egg showed large quantities of rock and slate, chestnut was complained of on account of the large quantity of pea it contained. As a result many consumers who have heretofore used egg coal in their furnaces have changed to stove for next winter. But even this change from one size to another has not caused any accumulation of either size in this market, and dealers continue to complain of the slowness of deliveries.

The mine owners are doing their best to overcome some of the loss in production so far this year in comparison with what was produced last year and the year previous. The mines are being operated as much as possible, and it is predicted that the tonnage figures for this month will compare favorably with those for April, which showed a substantial increase over those of the previous month.

The number of cars handled at the various local piers during the week ended May 16 was 5921 as compared with 6462 cars the previous week, a decrease of 541 cars. There were 3306 cars of anthracite standing on the docks on May 17.

The large producing companies claim to be booked well ahead for all the larger sizes, while many of the so-called independent operators are refusing orders for the time being, desiring to get rid of some of the orders now on their books before accepting additional business. Reports of premiums being offered for mixed cargoes of the domestic coals of so-called independents for quick delivery were current, but could not be verified.

Wholesale dealers report a heavy demand for all the larger coals from all sections of the country. There is a steady call from Canada, the West, and particularly from New England. None of these sections ought to complain of a lack of coal next winter if urgency counts for anything. Dealers are in frequent receipt of telegrams urging quick shipments.

Locally the demand is just as urgent. Many householders want their coal in the bins before they leave for the country or seashore, and retail dealers are kept busy explaining why they cannot get the coal. However, the dealers are employing all their help steadily.

There is not much activity in the local market for the anthracite steam sizes, but the so-called independent product is being readily absorbed along the line. Prices are strong for line trade, the better grades of buckwheat being quoted at from $3.15 to $3.40; rice, from $2.40 up, and barley from $1.50 up.

The trade has been curious concerning the interests to be included in the new retail corporation which is to be known as the William Farrell Son, Inc. There has been much guessing as to which of the present retail dealers will be included in the new company, but it was said early this week that no definite announcement would be made until the middle of the week.

Current quotations, white ash, per gross ton, at the mine and f.o.b. tidewater at the lower ports, are as follows:

	Mine	Company Circular
Broken	$6.05	$7.90
Egg	5.95	7.80
Stove	6.20	8.05
Chestnut	6.30	8.15
Pea	4.90	6.65
Buckwheat	3.40	5.15
Rice	2.75	4.50
Barley	2.25	4.00

Bituminous—The local tidewater situation is quiet. There is comparatively little doing in the spot market, but contract coals are moving in good shape. That a few weeks more ought to see a brisk market here is the opinion of many wholesale dealers. They see a trifle stronger market than existed last week, with bright prospects ahead.

Large manufacturers are said to be gradually entering the market, not wishing to be caught empty handed when the tide sets in, and are said to be about ready to buy large blocks at current prices.

There is a quiet but steady inquiry for the better grades, for which there is not much dickering in price. The poorer coals move slowly, some consumers wishing to take their chance of obtaining the better coals.

A betterment is noticed in production, and operators look for a still greater improvement as the season advances. There was a report current last week that central Pennsylvania operators had discussed the advisability of advancing the prices for the better grades of coal.

The railroads are buying heavily, and at prices ranging from $2.10 to $2.50, according to the district from which the coal is obtained.

Wholesale dealers look for an active market within the next few weeks. All-rail trade is picking up and prices are slightly better than on the tidewater basis. Most inquiries, however, lean toward the better coals, but these are scarce since most of the output is tied up in contracts. Operators having some free tonnage are not adding new contracts without considerable thought, and manufacturers who believe it will be easy to secure all the coal they require are likely to be disappointed.

There were handled at the local tidewater docks during the week ended May 16, 5597 cars of bituminous coal, as compared with 5133 cars the previous week, an increase of 464 cars. There were 3298 cars standing at the docks on May 17.

The quotations for the various coals at the mines, net tons, for spot delivery and contract, follow:

	Spot	Contract
South Forks	$2.90 to $3.25	$2.95 to $3.50
Cambria County (good grades)	2.75 to 2.95	2.95 to 3.25
Clearfield County (good grades)	2.50 to 2.75	2.80 to 2.95
Reynoldsville	2.50 to 2.75	2.75 to 2.95
Quemahoning	2.65 to 2.85	2.95 to 3.10
Somerset County (best grades)	2.65 to 2.85	2.95 to 3.10
Somerset County (poorer grades)	2.00 to 2.35	2.50 to 2.75
Western Maryland	2.25 to 2.75	2.50 to 2.75
Fairmont	2.00 to 2.25	2.35 to 2.50
Latrobe	2.10 to 2.25	2.25 to 2.40
Greensburg	2.25 to 2.35	2.35 to 2.60
Westmoreland ¾ in.	2.60 to 2.75	2.60 to 2.75
Westmoreland run-of-mine	2.35 to 2.60	2.35 to 2.65

PHILADELPHIA

Anthracite trade kept active by cool spring. Pea-coal situation greatly helped thereby. Stove and nut demand continues abnormal. Dealers plan to store nut this summer. Some complaint as to preparation. Present condition revives size-change talk. Retail price-cutting continues moderately. Steam demand unimproved. Buckwheat fairly taken; other sizes very free. Bituminous in fair demand. No call for spot coal. Some contracting. Rail agreements taken by some shippers.

Anthracite—Owing to the unusually cool weather which has prevailed beyond the middle of May, retail dealers have enjoyed a large business on coal for current consumption. This has done much to offset the last few months of winter, when business fell off so badly as to make most dealers pessimistic as to the future. The chief call has been for pea size, of which all dealers have a goodly stock.

With the heavy demand for stove and nut coal for summer storing, the cool weather has greatly assisted the operators in that it has enabled them to dispose fairly successfully of their production of pea coal. Early in the week this size threatened once more to pile up at the mines, but with the lowering of the temperature the calls for this coal became more active. The big companies are still compelled to place a fair volume of this size in storage, however, and occasionally one of the smaller operators cuts the price in order to move it. The practice of offering stove and nut if pea is taken is growing among some of the lesser shippers.

The heavy drive on stove and nut coal continues unabated, and yards are occasionally out of the first-named size. A disappointing feature so far this month has been the lessened production at the mines. Some of the local dealers are bitter in their complaints at not having their orders for stove and nut filled. They fail to realize that this market is at this time taking more stove and nut coal than ever before due to the consumers almost abandoning the use of the other sizes.

There has been some complaint recently as to the preparation of coal coming to this market. There are the usual complaints as to the sizing, such as a continuation of the practice of increasing the percentage of pea in nut, but in addition to this much of the coal coming in has entirely too much dirt in it, the dealers claim. We have seen some shipments recently which fully justified this objection, but we believe it is far from general. Most of the consignees are taking the coal in without going further than calling attention to it, as they realize that under present conditions they are likely to have their supply curtailed if they become too particular as to the preparation.

The present strong demand for stove and nut, to the exclusion of pea, has again brought up among the dealers the question as to the advisability of having the operators adopt the two-size plan which they attempted to effect a few years ago. Now, as then, the retailers seem to favor such a proposition, as it would simplify their work in many respects and wipe out the many complaints they receive from customers unable to get a particular size to the exclusion of others.

From the operators' standpoint conditions are good, but always with the possibility of trouble due to an overabundance of pea coal, which will accumulate the moment warmer weather comes to stay. On the other sizes—egg, stove and nut—they have plenty of orders on their books right now to keep them running for at least six weeks without taking another order.

The price-cutting situation among the retailers is improved if anything. The most extensive cutter who ten days ago increased his pea coal price from $8 to $8.75, and also made advances on the other sizes, continues at this schedule. There are a few instances of prices less than these, one or two still selling coal around $8.50. Fortunately, this is now confined to one section of the city and the tendency is for it to diminish rather than increase.

There is absolutely no improvement in the steam coal situation. All the orders for buckwheat are being filled, with at times a surplus existing with some of the larger producers. No trouble is experienced in finding a buyer for the better grades of buckwheat, as contract customers are taking advantage of the situation to put in their regular winter stock of this size. Rice coal is only fairly well taken, with quite a tonnage going into storage, as is also the case with barley. There can be no denying that the anthracite steam sizes have been much affected by the condition of the bituminous market.

The prices per gross ton for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$5.95	$7.80	Buckwheat	$3.40	$4.45
Egg	5.95	7.80	Rice	2.75	3.65
Stove	6.20	8.05	Boiler	2.50	3.50
Nut	6.30	8.15	Barley	2.25	3.15
Pea	4.90	6.50			

Bituminous—There is little activity in the trade, as with no spot coal in demand the production is kept down to the actual known needs of the market. Yet with it all the prices continue to be fairly well maintained within a radius of $3 to $2. Of course, there are at times a few sales for fine coals at a little higher figures, and vice versa. The inquiry for contract prices is still strong and with some new business being closed each week.

It is now known that a number of operators have closed contracts with the railroads for fuel supply. The prices range from $2.05 to $2.50, and some shippers hint that it is not for coal of particularly good grade. In some instances the contracts are only from month to month, while others have been made on a yearly basis.

The prices generally ruling at this time are covered by the following:

Georges Creek Big Vein	$2.90 @ $3.00
South Fork Miller Vein	2.90 @ 3.00
Clearfield (ordinary)	2.75 @ 3.90
Somerset (ordinary)	2.55 @ 2.70
Fairmont lump (ordinary)	2.40 @ 2.50
Fairmont mine-run	2.15 @ 2.25
Fairmont slack	1.90 @ 2.00

Lake Markets

PITTSBURGH

Increased activity brings closer price figuring. Market becoming steadier. Much railroad coal under cover.

With more activity in the local coal market there has been closer figuring upon orders, with the result that some lower prices have been made, particularly by operators who recognized that with a heavier operation costs per ton would be reduced and profits would be increased rather than decreased by making slightly lower prices than would have been considered a few weeks ago. The coal operators have a perfectly business-like attitude in this matter, their desire being to place the coal market squarely on its own feet, believing that it will be able to take care of itself. Almost without exception the operators look for a higher market next fall and winter than will obtain this summer. Accordingly, they will not make prices for deliveries to the end of the coal year nearly as low as the prices made for deliveries in the near future. The lowest regular sales of steam coal hardly go below $1.90, while there are sales up to $2.35 for early deliveries, depending upon grade, and for deliveries over the remainder of the coal year concessions from the basic price of $2.35 are relatively insignificant.

Slack has experienced a decline, as is usual at this season of the year, when increasing lake shipments (¾-in.) augment the production of slack. Steam slack is now selling regularly at $1.70 to $1.80, with gas slack 10 to 20c higher. Lake shipments are now of good proportions, particularly in the case of gas coal.

A large volume of railroad coal business is now closed, and purchases are continuing. Each transaction is made on its own merits, the character of the coal and its location being the governing elements. The railroads are paying neither more nor less than the general consumer would pay for the same tonnage, quality and delivery. The best Pittsburgh steam coal for railroad use to Apr. 1, 1920, is bringing $2.35, while there are sales of Panhandle coal, and even of Connellsville, at less.

The market is now quotable as follows: Best grades gas coal, slack, $1.80@2; mine-run, $2.35; ¾-in., $2.50@2.60; 1¼-in., $1.60@2.70. Steam, slack, $1.70@1.80; mine-run, $1.90@2.35; all per net ton at mine, Pittsburgh district. Byproduct coal is not quotable, as there is scarcely any movement.

BUFFALO

Coal trade conditions show little change. Shippers hopeful. Anthracite in sharp demand. Rail trade cuts in on lake movement.

Bituminous—While the tone of the reports coming from shippers is better than it was, coal must move more freely to bring about prosperity in the industry. The jobbers are doing what they can to maintain prices. In fact, they say they are doing more in that direction than are the operators. The signs of weakness in the slack trade would not have been in evidence if more of this fuel had been put into stock. It is customary to do that at this time of the year, and it might have been done now; but certain mines seem to have taken the view that it was best to sell it for what it would bring.

Canada still has considerable stocks of bituminous coal and wood that were bought to meet the demand last winter. Consumers are slow to contract for future requirements, while the fact is that the sellers do not care to bind themselves to anything that is likely to distress them later on.

While bituminous prices are not strong they are fairly steady at former figures: $4.65 for thin vein Allegheny Valley; $4.45 for Pittsburgh and No. 8 lump; $4.20 for same mine-run; and $3.80 for all slack, per net ton, f.o.b. Buffalo.

Anthracite—The demand is active locally and in all-rail markets, though the orders from upper-lake districts are not numerous. All that really disturbs the shippers is that if they yield to the eastern demand they may find themselves unable to get as much coal to the Northwest as they will need for winter. For a short time the lake loadings fell off badly, but now the shippers have returned to that branch of the trade and will endeavor to keep it up. This tends to make the local demand still more insistent; but that must go on for a while, as it is not possible to mine all the coal this summer that is to be used throughout the year.

The shipments by lake for the week were 97,100 net tons, of which 52,100 tons cleared for Duluth and Superior, 25,900 tons for Milwaukee, 7000 tons for Waukegan, 6000 tons for Chicago, 3200 tons for Fort William and 2900 tons for Marquette.

The city prices of anthracite to the end of May will be as follows:

	F.o.b. Cars Gross Ton	At Curb Net Ton
Grate	$8.65	$10.35
Egg	8.55	10.30
Stove	8.80	10.20
Chestnut	8.90	10.60
Pea	7.10	9.15
Buckwheat	5.80	7.85

With 25c. additional for loading to lake vessels.

CLEVELAND

Domestic bituminous coal is advancing in price while steam-coal is weakening. Demand for the latter is expected to improve as a result of the demise of the Peek Industrial Board. No. 8 operators still complain of large accumulations of slack. Lake coal is more plentiful than cargo space just now.

Bituminous—Domestic consumers apparently are heeding the warnings that coal next winter is likely to be scarcer and higher, and demand is reported quite brisk. This is especially true of Pocahontas, and receipts are no more than equal to sales. Anthracite and domestic bituminous are being carried along on this buying wave. Some retailers have marked Pocahontas prices up another 25c., while West Virginia splint prices are due for a similar advance next week.

Steam coal, on the other hand, is moving rather slowly, though the outlook the past few days has taken a decided turn for the better. The industrial atmosphere seems to be clearing, as a result of the determination of the Peek Industrial Board. Iron and steel mill operations will increase shortly, it is believed, and while the summer run will show considerable fluctuation the trend all the time will be toward improvement. Huge piles of slack, which they are unable to move, are causing considerable concern to No. 8 district operators.

Considerable discussion of increasing costs is to be heard at present. Cost sheets are showing an unexpectedly heavy upturn, operators say, while at the same time they are expected to revise their prices downward. No. 8 district mines now are operating at about 55 per cent. of capacity. Whether they could do 10 per cent. more were every condition ideal is a question. Labor is scarce, skilled workmen are found to have left in unexpectedly large numbers, and what remains is markedly inefficient.

Lake coal seems to be settling around the $2.35 mark. With railroads taking most of their mine-run supplies from Ohio mines at $2.10, this figure now is probably the average for mine-run sales. Slack is reported as low as $1.50 in the past few days. Net ton delivered steam coal prices in Cleveland now are about 20c. lower than they have been.

The report of the Pittsburgh Vein Operators Association of Ohio for the week ended May 7 shows shipments totaling 5563 cars, divided as follows: Railroads, 988 cars; lake trade, 3685; Ohio, 698; Michigan and Indiana, 167, and Canada, 75. Car supply is approximating 100 per cent.

Lake Trade—Because of the delay in getting some of the larger lake freighters on the run this spring more coal cargoes are being offered at Lake Erie ports than carriers are available. The number of cars being handled by the car dumpers is increasing daily, and has run as high as 3300 cars in one day. All indications are that for some time, at least, bituminous coal will be moved up the lakes as fast as carriers are available.

Prices of coal per net ton delivered in Cleveland are:

Anthracite	
Egg	$10.85@10.95
Chestnut	11.15@11.25
Grate	10.95
Stove	11.05@11.15
Pocahontas	
Forked	8.50@ 8.75
Lump	7.75@ 8.00
Mine-run	7.20
Domestic Bituminous	
West Virginia splint	7.30@ 7.40
No. 8 Pittsburgh	6.10@ 6.35
Massillon lump	7.30@ 7.40
Steam Coal	
No. 6 slack	4.10@ 4.30
No. 8 slack	4.50@ 4.65
Youghiogheny	4.70@ 4.90
No 8½ in. lump	5.15@ 5.30
No. 6 mine-run	4.20@ 4.30
No. 8 mine-run	4.50@ 4.65

DETROIT

Inquiries for bituminous coal are reported rather more numerous, but sales seem to have made no marked increase.

Bituminous—While some of the jobbers find reason for believing a larger interest in the bituminous supply is developing in the Detroit market, owing to a slight increase in number of inquiries from manufacturing plants, the apparent improvement is said not to have progressed to a tangible growth of orders. The business is still pronounced unsatisfactory with sales falling far short of what jobbers believe should be their level at this time of the year.

Criticism is also directed at the breaking of prices below the schedule fixed by the Federal Fuel Administration, and some of the jobbers intimate that dealers who have been emphatic in urging the advantages of price stability appear to have been among those who sought to increase sales by offering concessions.

Approximate quotations at the mines, on a long-ton basis, place Hocking domestic lump at $2.50 a ton, mine-run at $2 and slack at $1.50. Coal from other leading districts of Ohio is said to be available at about the same prices. West Virginia splint or gas lump is quoted at $2.65, the three-quarter lump at $2.50, mine-run at $2.25 and slack at $2. Although little smokeless coal is arriving in Detroit, Pocahontas mine-run can be had, it is said, for $2.75 at the mine.

Heavy stocks remaining in possession of consumers of steam coal and in yards of retailers are described as constituting the chief check on sales, and progress in reduction of these stocks seems disappointingly slow.

Anthracite—Domestic buyers are not showing the willingness to stock up early that the experiences they have passed through during the last two seasons should develop, according to dealers. While receipts of anthracite are not of large amount, the supply is said to be sufficient to meet present requirements for each of the sizes favored for household heating plants.

Lake Trade—Shipments over the lake routes consist very largely, so far, of coal sent to producers' own docks. The supply of vessel capacity is more than equal to requirements of the tonnage moving. Owing to the scarcity of ore and grain cargoes for loading downbound vessels, a few of the carriers are coming down light to load coal, while a few that loaded coal some time ago, have not yet started their first upbound trip.

COLUMBUS

There is a better feeling in the Ohio coal trade due largely to the award of railroad fuel contracts. Operations are more active and future prospects are better. A period of activity is predicted during the next 60 days.

The award of railroad fuel contracts, amounting to about 4,000,000 tons from Ohio mines, has stimulated the trade to a marked extent. The contracts were generally awarded at low prices, but on the whole the result will be that mines which have been idle for some time will resume operations. The general result is a better feeling in producing and shipping circles, and a large part of the gloom of the past few months is rapidly disappearing.

Beginning at once, the output of the various Ohio fields will be increased fully 50 per cent. over previous production figures. This is especially true of the Hocking Valley field proper, where operations have been working at about 35 to 40 per cent. of capacity. They are expected to reach 75 per cent. within a short time. In the eastern Ohio field a considerable part of the railroad tonnage will be produced, and operations will be correspondingly increased. Contracts for steam tonnage are still slow, although there is more of a disposition on the part of purchasing agents to secure data and figures.

The lake trade is also becoming more active as the season progresses. Shipments from the lower lake ports to the head of the lakes are becoming larger. Many lake agreements have been entered into with the price left blank, to be supplied later. Quite a few of the Ohio producers have their own docks in the upper lake region, and thus price is not a material matter at this time. The records of the loadings at the Toledo docks are showing up pretty well, and the same is true of loadings at other Ohio lake ports.

The domestic trade is still quiet, although some school contracts are being awarded at this time. The better grades, such as Pocahontas and West Virginia splints are in good demand, and prices are ruling higher. Ohio-mined grades are not moving well, although some dealers are inclined to buy better. Retail stocks are fairly well used up and not a great deal is being carried over. It is believed that the retail trade will open fairly early, and many dealers have made preparations accordingly.

CINCINNATI

Heavy demand for smokeless. Contract business picking up. Domestic demand better, with prices steady.

The coal situation in Cincinnati is still quiet, the consumer remaining sanguine that there will be a sharp decline in price when the peace treaty is signed. One of the prominent coal dealers in this city, when interviewed in regard to the coal situation, had the following to say about conditions. "The consumer is still withholding orders, anticipating a drop in price. This decline, however, will fail to materialize; in fact, there is seen in the future a surer possibility of a rise in price. This condition might be changed somewhat after the meeting of the national association in Chicago, when the general public will learn the true state of affairs. They will be advised of possibilities of another serious car shortage, which will result in a repetition of 1917 conditions. While the sales in Cincinnati are not what they should be, there is a steady increase, and some lines in particular have shown an improvement. Smokeless coal has taken a sharp rise; the heavy demand for this grade continues, and the dealers are experiencing some trouble in filling orders as the supply on hand is rapidly diminishing."

There were several large orders placed last week for steam and semi-steam grades, and the contract business is looking up, several large contracts being signed. The demand for domestic grades has somewhat improved with prices steady. Prices on coke experienced a sharp break owing to a falling off in the demand.

LOUISVILLE

Domestic prices strong, with a fair demand for block and egg sizes. Steam grades and mine-run in dull demand, and operators being forced to cut prices in order to move steam. Contract prices fairly firm.

Domestic prices are firm and stronger in practically every field of the state. In the Harlan and Hazard fields operators are getting from $2.85 to $3.10 per ton for block. In the Straight Creek field a price of $3.15 to $3.25 is asked, while on Jellico prices have advanced to $3.25 to $3.50 per ton. It is reported that Blue Gem coal is selling all the way from $3.50 to $4 a ton. Western Kentucky operators recently cut the price 5c. per ton on block, or from $2.60 to $2.55, making the latter price the standard. However, some western Kentucky spot block is selling at as low as $2.20.

Retailers have been stocking their yards freely, and are getting a few stocking orders from consumers. However, consumers are not stocking as they did at this time last year, and instead of being rushed things are a little dull with the retailers. However, the demand for block coal is coming better, and late buyers will probably meet with a high market.

In the coal fields the entire feature is the demand for block coal. Mine-run and nut and slack prices have gone off badly during the past two weeks. These reductions, however, are on spot coal only, as contract coal is holding firmly, due to the uncertain labor situation. Western Kentucky steam prices show mine-run quoted as low as $1.85 for spot, with the average market at $2.10 to $2.35. Nut and slack is selling at around $1.70, with poor grades quoted as low as $1.40. Some thin slack is selling as low as $1.40, it is reported. Local dealers report some Indiana run-of-mine offered on the market at $1.50 during the week.

Eastern Kentucky nut and slack is selling at prices ranging from $1.50 to $1.85 per ton, and mine-run at $2 to $2.35. It is understood that eastern Kentucky mines quoted $2 to $2.25 on mine-run to the Louisville & Nashville R. R., and that western Kentucky quoted $1.60 to $1.70 on the Louisville street railroad contract.

Coal is going principally into Michigan, Ohio, Indiana and Kentucky, with some movement into Georgia on mine-run. The Louisville & Nashville lines handled 301 cars of coal from Kentucky for the Lake district after Apr. 20 and up to May 1. The lake movement is now getting into good swing.

BIRMINGHAM

Demand for steam coal fails to show improvement. Strong inquiry for domestic fuel continues. Supply inadequate to meet requirements. Production from steam-domestic mines confined to half-time operations, there being no surplus stocks in the hands of producers.

General industrial inactivity continues to affect the coal market in this district, and sales of steam fuel are being held down to current requirements of users. Trade conditions may be stated as satisfactory when considered in relation to the business of consuming interests, but not otherwise.

Both the wholesale and retail channels of domestic trade are featured by a good demand, and few domestic operations have any tonnage to offer between now and the end of the year. Such relief as may come will depend on the output of the steam-domestic operations which are now either

idle or running only half time, when such mines are again restored to full-time schedules.

Basic conditions in both the steam and domestic trade are considered stable, prices remaining firm and unchanged, with a strong probability of a shortage of domestic coal during the coming fall and winter. Retailers are now carrying on an advertising drive, in which consumers are urged to not delay in providing their supply of fuel for winter consumption.

Some improvement in production will soon be noted from the mines of furnace companies, the Woodward Iron Co. starting up one or two mines to supply coking coal on account of putting one of their furnace stacks in operation. Otherwise there is no change in the production end of the trade.

Coke

CONNELLSVILLE

Continued decline in coke production. Fairly active prompt market. No contracting as yet for second half.

With the continued decline in coke production in the Connellsville and Lower Connellsville region, there is less coke available for odd-lot sales and the spot market has stiffened further. It has now closely approached the level of values obtaining on monthly adjustments of contracts, just as should be the case. While $3.60 and even $3.50 was done on spot lots of furnace coke three or four weeks ago, the common quotation now is $4, and $3.75 could be done, if at all, only with difficulty. Nearly all contract settlements for May delivery were at $4.

Furnace coke shows a somewhat broader demand, but is not quotably higher. Iron foundry operations are evidently increasing, and as there was less contracting for foundry coke for the present half year than usually occurs, there is a fairly active prompt market.

More than half the furnace coke contracts now in force expire June 30, and both furnace men and coke operators are beginning to consider the matter of second-half contracts. There have been hardly any active negotiations as yet, and the feeling of the two parties is not disclosed; but the guess may be hazarded that coke operators would quote a flat price of $4 for the second-half while furnacemen would talk $3.50 or less. It seems improbable that contracts will be renewed on the basis of monthly price adjustment. This system has worked fairly well during the transitionary period since Government control was removed Feb. 1, but for the future both buyers and sellers prefer to settle the matter of price when they make the contract, rather than later in six monthly installments. Sliding scale contracts, based on a ratio of coke to pig iron, may however be considered.

The spot market is quotable at $3.75@4 for furnace coke and at $4.25@5 for spot foundry, per net ton at ovens. There is no contract market quotable.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended May 10 at 100,980 tons, a decrease of 32,626 tons. In some quarters of the trade doubt is expressed whether the decrease in production has been as great as stated.

Buffalo—The trade continues dull, with little prospect of improvement in the immediate future. The fact that the demand for iron ore at the furnaces is still light shows the condition of the iron market to be quiet. The movement of ore down the lakes has begun, but only a few of the steamers have been ordered into it. Ordinarily they would all be busy by this time. Prices remain at $7.25 to $7.60 for 72-hour foundry coke; $6.60 to $7 for 48-hour furnace, and $6.10 for off grades, per net ton, f.o.b. Buffalo.

Middle Western

MILWAUKEE

Coal market is quiet and uneventful. Prices of all grades well sustained, however. Cargo receipts brisk for this season.

The coal market at Milwaukee at present is quiet and devoid of anything worthy of special mention. Deliveries are being made at a normal rate only, as it is altogether too early to expect consumers to burden their minds with thoughts of another winter supply of fuel. Pocahontas of all grades is easily obtainable this year, and many are turning to this class of fuel because of the high price of anthracite. Illinois coal is being held up, despite heavy stocks everywhere. Production has been curtailed to meet the situation, and it is apparent that there is organized effort to sustain the price of western coal. There is considerable complaint as to the poor quality of coke now on the market. Those in position to know say the byproduct plants were compelled to use Illinois coal to some extent last winter, with the result that the coke is not up to the usual standard.

ST. LOUIS

Market continues inactive, with practically no demand for anything and a tendency on the part of the Standard operators to continue cutting prices. Both steam and domestic inactive in the city and country.

There is no change in the local situation from that reported for the past few weeks. There is practically no call from the country for coal, and there is nothing to indicate that the domestic user in the country will do much storing before July or August, if then. The first country business will come from the threshing, which is expected this year about the middle of June. Beginning the first of June, therefore, there will be some threshing coal moving; but this seems to diminish in tonnage year after year, owing to the growing use of gasoline tractors.

The country demand is rather good for anthracite chestnut sizes. This coal is moving south through St. Louis for the first time in years to points in Texas and Oklahoma, and to places in Arkansas and the southwest. This is accounted for by the fact that no anthracite is moving via boat to New Orleans as in previous years, and such demand as comes from the southwest must be taken care of all-rail.

The local demand is off on everything. There is a little coal going into storage for domestic purposes, but it is so small that it is hardly noticeable.

In the Standard field the feeling prevails that every mine must work, with the result that the few that are working are cutting prices to get the little tonnage offered. The only thing in the field that looks at all promising is screenings, which seem to be getting stronger all the time.

Some mines work one day a week, some not as many as three days a week, and some have been idle for many weeks. Dissatisfaction is growing among the men.

In the Mt. Olive field conditions are somewhat better. Prices are rather firm, and there is a feeling of satisfaction with the business that this field has been able to take care of up to the present.

In the Carterville field of Williamson and Franklin County some improvement has been noticed during the past week in the movement of domestic sizes. There is at the present time a shortage of screenings and steam sizes. All the mines are on short time, but a fairly good tonnage seems to come in from the Northwest on domestic coals, while there is nothing doing in the St. Louis territory or south thereof. The same condition applies to the Duquoin field.

Cars are plentiful and movement is good. The Franklin County operators are expected to raise their prices on June 1 10c. above those quoted below, which are prices prevailing today:

Williamson and Franklin County Association:	Mt. Olive and Staunton	Standard
Lump, egg and nut	$2.75	.....	.....
Washed Nos. 1 and 2 nut	2.85	.....	.....
Independent:			
Lump, egg and nut	2.55	$2.55	.....
Lump and nut	....	....	1.90@2.10
Washed Nos. 1 and 2 nut	2.85	.....	.....
Mine-run	2.35	2.20	1.60@1.70
Screenings	2.20	2.05	1.25@1.40
3-in. lump	....	2.30	.....
2-in. lump	....	.....	1.75@1.90
2x6 egg	....	.....	1.80@2.00

Williamson-Franklin County rate to St. Louis is $1.07½; other rates $0.92½.

General Statistics

ANTHRACITE SHIPMENTS, APRIL, 1919

The shipments of anthracite for the month of April, as reported to the Anthracite Bureau of Information, show a substantial recovery from the slump which prevailed during the two closing months of the coal year 1918-19—February and March.

The quantity shipped from the mines in April amounted to 5,224,715 tons, as compared with 3,938,908 tons in March, and 3,871,932 tons in February.

The increase over March shipments was 1,285,807 tons. Notwithstanding this decided increase over March, the shipments in April this year were 1,143,658 tons less than in the corresponding month last year, when they amounted to 6,368,373 tons. The difference in weather conditions in the winters of 1917-18 and 1918-19, and also the speeding up of production last year because of the war, account for the smaller tonnage last month as compared with the corresponding month last year. As compared with April, 1917, the shipments last month showed a decrease of less than 370,000 tons.

The shipments by companies were as follows:

	April, 1919	April, 1918
P. & R. Ry.	1,044,192	1,233,512
L. V. R.R.	865,924	1,175,027
C. R.R. of N. J.	481,781	528,886

COAL AGE

Volume 15 New York, May 29, 1919 *Number* 22

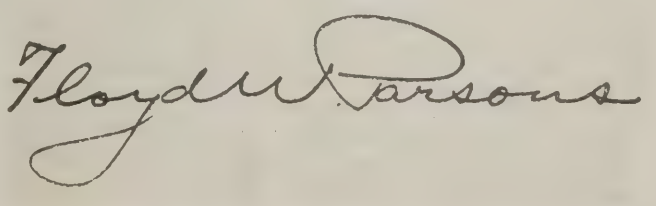
A Parting Word

Dear Friends:

Nearly eight years ago the first copy of a small and modest, but rather hopeful, mining weekly was submitted for the attention and approval of the coal fraternity. That paper was COAL AGE, and almost to a man the original crew that embarked on the journalistic adventure is still busy trimming sails and bailing out the water that was shipped in occasional high seas.

Unlike most editorial organizations of a similar nature, the staff of COAL AGE had a chief in name only. Of course, it was necessary to have someone sit in the pilot-house, look at the compass and see to it that the boat didn't run in circles, which job was mine. And although at first I felt quite necessary at the wheel, it soon became evident to me that the rest of the crew also knew north from south and were perfectly able to perform the captain's duties at any and all times.

It is a fact, therefore, that my associates on this journal have never worked for me, but always with me. We have all shared alike in the numerous discouragements and felt equal joy over the successes. If the respect and friendly cooperation of America's great coal industry has been gained, it was accomplished through the paper constantly reflecting the ideals, not of one man, but of several loyal workers, who have stood fast on the platform that modern industry is a four-cornered affair. It must deal squarely, not only with capital and labor, but also with the people as represented by the state, and brains as represented by management.



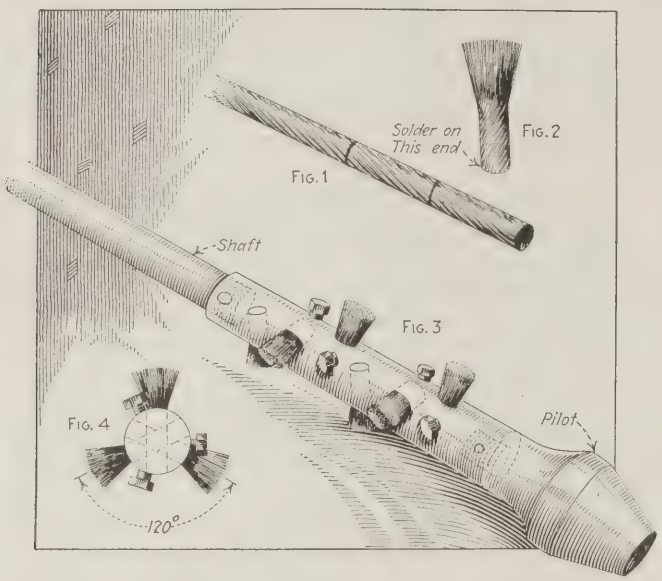
I am resigning from COAL AGE with this issue, after having spent the happiest years of my life in helping build it. If I were not certain of the great future of the paper, nothing could induce me to leave; if I were not aware of the splendid abilities of my associates who will "carry on" so successfully, no possible inducements could lure me away.

The coal industry is the one business I have served continuously since the day I left college to earn my first dollar. No man can labor in the dark chambers of Mother Earth, face the perils of death that lurk there, help carry the lifeless forms of his buddies to daylight, and then forget. I have my friends in and about the mines in thirty states. To me they constitute the greater part of the whole world in which I move, and I want it always to be just that way. No doubt I can take my body elsewhere, but the heart of me stays in the mines.

In the new field I enter, it is my hope that there will be opportunities to serve the great industry I love, and if such chances appear, it will be no fault of mine should I fail. But the real editorial work that will be of profit to the coal industry in the future, as in the past, will, of course, be carried on in COAL AGE. R. Dawson Hall, who has worked hand in hand with me from the day of the christening, has qualities so rare they arouse in me a feeling of envy. Indefatigable in his work, loyal to his friends, uncomplaining when the way is rough, consistent and faithful to the demands of justice, he has grown largely in the esteem of his intimates and the respect of his company.

No men are better equipped to continue the plans and policies of this journal than Messrs. Hall, Beard, Kneeland, Moss and Harris. What little there will now be of added responsibility for them will be taken care of by the greater play of latent powers that now have a still better opportunity for individual expression. COAL AGE has preached humanity and democracy in industry, and we are happy to apply these teachings in our own case by recognizing and rewarding merit. When a company must go outside its organization to pick men for the jobs higher up, there need be no doubt of the injustice and inefficiency of that corporation's management.

If the words here used and the method employed in thus saying adieu are at all unusual, it is because my feelings in the matter are unusual. In my heart at this moment are but two thoughts: The first—Thanks for ten thousand favors; the second—good luck and an ocean of success.



IDEAS AND SUGGESTIONS

Unique and Durable Tube Brush

BY CHARLES H. WILLEY
Concord, N. H.

The tube brush shown in the accompanying illustration may seem a rather queer-looking affair, but if any of the readers could step into the boiler room of the plant with which I am connected and see a set of these homemade brushes driven by air motors, chasing out the havoc created by a week's run on "bugdust," they

FIGS. 1 TO 4. DETAILS OF A HOMEMADE TUBE BRUSH

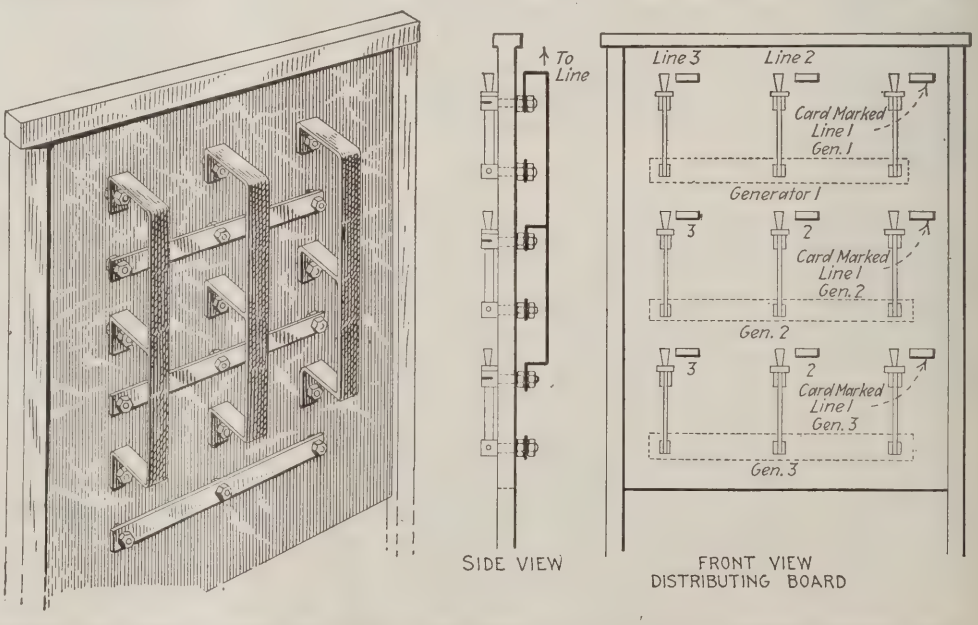
would get busy and make up a few of them for their own use.

The idea for these brushes came to me after I had consumed many dollars' worth of standard spiral tube brushes. I had searched the advertising pages of several trade papers for some sort of a tube or flue brush that would permit the renewal of the wire fagots, but none could be found. So I set out to make such a brush. The wire used was some $\frac{3}{8}$-in. eight-strand cable from the scrap heap.

A length of this wire was soldered at points $2\frac{1}{2}$ in. apart, as indicated in Fig. 1, and then cut into short lengths. Then in a piece of round bar stock (Fig. 3), $1\frac{1}{4}$-in. in diameter, a series of holes was drilled at 120-deg. angles along the piece and into these were inserted the short lengths of cable. The soldered ends, as indicated in Fig. 3, assisted in this insertion. Each piece was secured in its hole by a set screw, as shown. The large pilot was screwed onto the end of the brush, thus making it easy to enter the brush into the tubes. The other end of the brush head is provided with a shaft whereby the device is revolved.

In use the brushes are pushed through the tube while revolving to the right, and then the air motor is reversed and the brushes pulled back while turning to the left. This not only keeps the brushes from laying one way and gives them longer life, but it results in a better cleaning job. One set of brushes will last long enough to pass through and back again in 600 four-inch flues, 8 ft. long. It is then only a few minutes' work to put in new pieces of cable.

Three Different Types of Switchboard

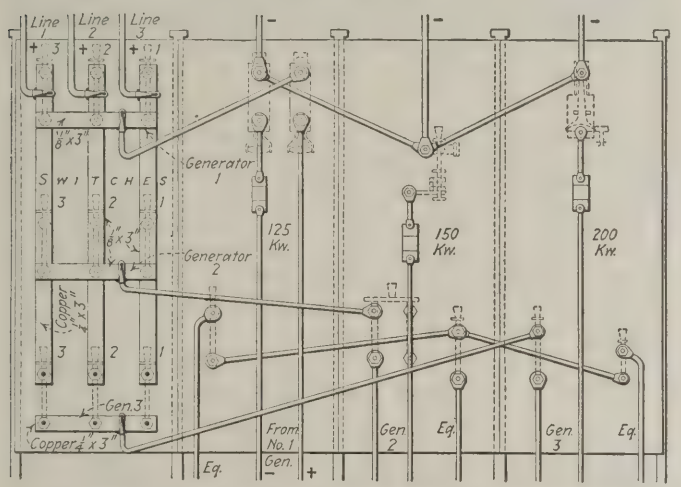


BY J. J. NOLAN
Linton, Ind.

The accompanying illustrations show three different makes of switch boards installed in one plant. This makes it inconvenient to install bus bars on account of the wide difference in the location of the studs on the rear of the boards as will be seen.

Seven hundred and fifty thousand circular mil, stranded, covered cable was substituted with terminal lugs in place. The station where these boards are installed supplies current to three different points as shown by the top of the distributing board.

Lines Nos. 1 and 2 furnish current to motor driven centrifugal pumps in the mine and line No. 3 supplies mine locomotives and mining machines. This line must be kept separate from the pumping load because short circuits would be injurious to motors and pumps.



The distributing board shown is of original design and was intended to prevent mistakes in throwing in

SIDE AND FRONT VIEWS OF THE DISTRIBUTING BOARD FOR THREE GENERATORS

switches when changing over from one unit to another, paralleling, etc. As will be noticed any one of the generators can be connected to either Nos. 1, 2 or 3 line separately, either two or three paralleled on one line or all three lines as needed while in case of breakdown any line can be operated from any unit. The parallel connections are of course placed on the distributing board.

For example, suppose No. 3 generator was supplying current to No. 1 and No. 2 lines, No. 2 and No. 3 switch on lower row would of course be closed and it was desired to put No 2 generator on this load and close down No. 3 generator without stopping the motors. After building up voltage on No. 2 generator close

REVISED LAYOUT OF GENERATOR CONNECTIONS

No. 2 and No. 3 switches on the distributing board in middle row, close breaker and double pole switch of No. 2 generator (this parallels the two), trip breaker and pull single pole knife switch on No. 3 generator (this separates them), then pull No. 2 and No. 3 switch on lower row of distributing board. In this operation it is hardly necessary to use the equalizing switches.

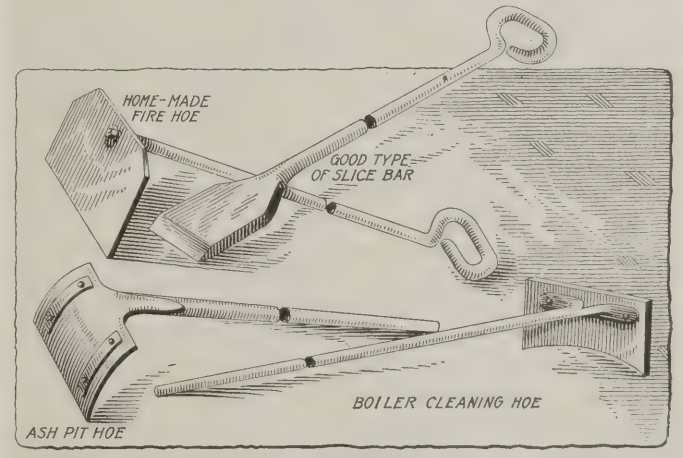
This arrangement makes a handy but simply arranged layout in both front and rear of the board and has more than paid for the expense incurred in its installation through preventing mistakes which might have occurred damaging the equipment.

Alarm in Case of Mine Fire

As soon as word of a mine fire or an explosion is received, an alarm should be given and assistance summoned by an official or employee of the mine. In case of fire within the mine or in the entrances, the alarm should be sent immediately to all parts of the mine in order that the men may escape, and efforts be made at once to put out or control the fire. In case of an explosion, aid will necessarily be needed. All employees not engaged within the mine should be hastily summoned to appear near the mine entrance, and help should be asked from near-by mines. The call for assistance should be for mine foremen, firebosses, electricians, mechanics, hoisting engineers and timber and brattice men. Reliable men should be stationed at once at all entrances to prevent any but safety or electric lamps being taken into the mine and to make a written list of all who enter.—*Rescue and Recovery Operations in Mines.*

Fire Cleaning and the Tools Therefor

By Jack L. Ball
Amsterdam, Ohio



When the length of the grate bars of a boiler furnace is not over 6 ft., the quickest and easiest way of cleaning fires is to push the live coals back to the bridgewall, pull out the ashes in front, pull the fire forward and then clean the back of the grate. The method of "kicking" over one side at a time is uneconomical for these reasons: It is necessary to have one fire door open while cleaning, thus allowing great quantities of cold air to enter the furnace; it requires a longer time to clean; and it will be noticed that when a fire is "kicked" over a large amount of pit ashes is the result.

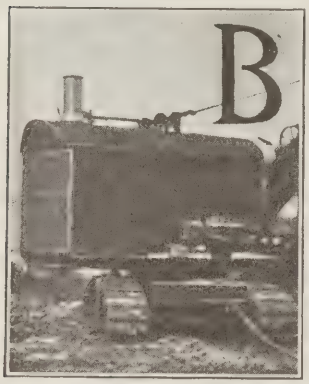
If the method of pushing the fire back is used, the following advantages will be noticed: The time required to clean fires is reduced to a minimum; the fire doors can be kept nearly closed while pushing back the fire, thus preventing a large amount of air from entering the furnace; also, the fireman is not exposed to the heat to any great extent. It is true that a small amount of ash will be pulled over with the fire, but the quantity will be small if a little care is exercised.

The handle of a fire hoe usually breaks near the blade, at which place the handle is usually welded. If the hoe is drilled and tapped, and the handle threaded, the blade can be securely fastened to the handle with check nuts, as shown in the accompanying illustration. This method insures a quick repair if repair is necessary, and will save the blacksmith the task of welding and riveting.

A good slice bar is shown below. It will be found to be an excellent tool for freeing clinkers from the grate bars; also, it is effective when used for "spudding" loose the clinkers that adhere to the furnace walls.

For cleaning ash pits, the ash-pit hoe shown was

HANDY TOOLS FOR CLEANING BOILER FIRES



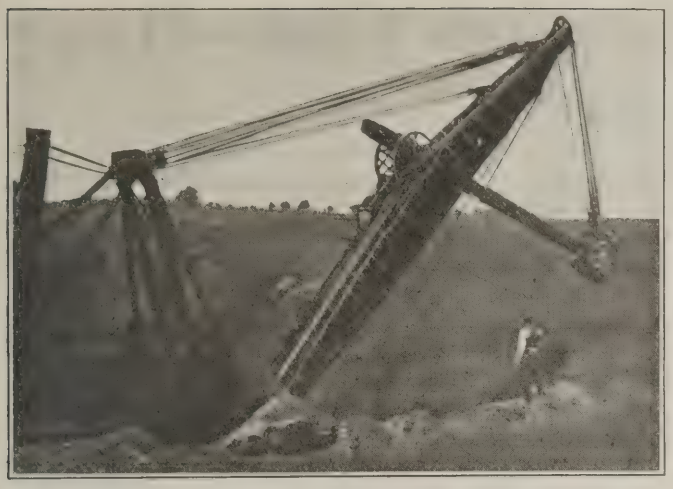
made from a discarded No. 2 coal shoved. This was bent and braced as shown and provided with a long handle. It is surprising how quickly and easily an ash pit can be cleaned with this homemade tool.

If horizontal return tubular boilers are fed through the front head, it will be noticed that much loose scale will be deposited at or near the blowoff connection of the boiler. It is often necessary to clean a "hot" boiler. As it is impossible for a man to get into it for the purpose of removing this scale, the boiler-cleaning hoe shown will come in handy for pulling this scale to the front end of the boiler so that it can be removed.

Machinery Used in the Stripping of Coal

By S. B. Creamer
Cambridge, Ohio

SYNOPSIS — *Describes stripping practice in Ohio as regards the types of machines used both to strip the coal and load it into cars. The comparative advantages of steam and electrically driven shovels are noted. The latter are gaining in favor wherever electric power is readily obtainable. The recovery of coal by the open-pit method of mining and the loading of it into cars by a power shovel, introduce more careful preparation in the tipple where impurities are removed.*



BOTH steam and electrically driven shovels are used in the stripping of coal. These shovels are massive machines of the revolving type, weighing approximately 350 tons with 80 to 90-ft. booms; they dig a cut 100 to 125 ft. wide and place dirt 145 to 165 ft. from the digging face. A 1⅜- to 1½-in. wire cable 365 ft. long is used on the hoist. This rope has an average life of from one to six months, depending upon the nature of the material dug and the running time. The shovels are carried on four sets of narrow-gage trucks—one set under each corner—and these run on two tracks 25 ft. between centers. Each type has its advantages, but much depends upon local conditions in determining the power to be used. The steam machine has had a preference. However, the electric type is gaining in favor.

There are many advantages in the use of electric power on shovels, and where it is cheap and reliable it is rapidly coming into use. There is much less vibration in a rotary electric motor than in a reciprocating steam engine, and the reduction of vibrations, due to various causes, not only reduces the amount of repairs but prolongs the life of the machine. With the electrically operated shovel steam lines with leaking joints are eliminated; less oil is used; a cleaner shovel is possible and delays due to cleaning fires are done away with. This delay is unnecessary with machines having two boilers, however, as one boiler has sufficient capacity to operate the shovel. Thus the fireman can clean the fire in one boiler while the shovel runs on steam from the other. Some may say that the cold air drawn in by the exhaust is injurious to the flues, but this can easily be prevented by the three-way valve in the exhaust line which turns the entire exhaust into either stack or both as desired. When boilers are used ashes are deposited on the coal. This dirt is eliminated when electricity is the motive power on the shovel; in the latter case expensive water supply and frozen pipelines are done away with, and labor is reduced to a minimum. Five to six men compose a machine crew on the electric shovel—a runner, a craneman, an oiler and three pitmen. The craneman often is omitted. Compare this with eight men on the steam machine; this crew includes a runner, craneman, oiler and fireman, with four men in the pit. The extra man in the pit is required to keep the shovel supplied with coal. When it comes to speed, the electric shovel is practically automatically controlled and "foolproof." It is impossible to speed it up as in operating the steam machine. When there is an overload, as there often is in pulling heavy stones, an increase in power above the capacity of the machine cannot be provided for at the electric control, as is often done at the steam throttle. The manufacturers arrange for a fuse to burn out instead. This prevention of an excess overload may save thousands of dollars on repairs and shovel upkeep, as well as add life to the cable. Ashes are not dumped on the coal and trenches are not dug in it, as is done when obtaining fuel for use on the steam shovel; these trenches frequently make extra trackwork. Some insist that it is unnecessary to dump ashes on the coal, but this is hard to prevent entirely. Six and 8-cu.yd. buckets are used on these shovels. However, the use of a 5- or 6-cu.yd. bucket is to be preferred over the 8-yd. bucket, on account of less strain. Yet with all the advantages of the electric shovel, the reliability and flexibility of the steam machines give them much prestige. With a supply of coal and water they can operate regardless of location.

The shovel used to load the coal is a much smaller machine than the stripping shovel; it is also of the revolving type. Shovels with booms from 28 to 32 ft. in length give the best satisfaction. The most valuable asset of this type of machine is the caterpillar tractor, which completely eliminates the use of pontoons and makes possible its operation with one pitman. On these small machines steam power has many advantages over the electric drive. While the large electric shovel is a machine run by three motors, the small one is operated by only one motor. The hoist, crowding and swinging mechanisms are operated by friction drives from this one motor, making impossible the "speeding up" of the machine while loading trains, as is possible with steam shovels. These shovels being small, it is easy to

STEAM SHOVEL USED TO LOAD STRIPPING COAL

STRIPPING COAL BY SHOVEL IN OHIO

increase their speed, and each minute saved in loading trains means cheaper production. On the other hand, only two men are required on the electric machine, the runner and pitman, while three men are required on the steam machine—a fireman being necessary.

The great advantage with the steam coal-loading machine, as with the "stripper," is its great flexibility. With the aid of a team to haul coal and water, and an extra man to help with the caterpillars, the shovel can be moved a distance of two miles in 10 to 16 hours. This, of course, depends upon the topography of the land. Such a move would be impossible with an electric machine, as the cost of power transmission would be prohibitive. These shovels can climb a 20 to 30 per cent. grade, but they must be moved straight up or down the hill. If an attempt is made to follow the contour of the hill, trouble is encountered by the trucks jumping the caterpillar belts. The only objection to the steam loading shovel is the leaking of flues in the vertical boiler. Much of this leakage is caused by mud on the flue sheet, which can be prevented by cutting out two or three flues every four or six weeks and "washing out" with water under high pressure. There are some objections to this, but they are negligible in comparison with the results obtained.

The haulage equipment depends largely on the plant layout. If coal is loaded directly into standard-gage cars, which is quite undesirable, one standard-gage 50-ton dinkey will serve one loading shovel. The big objections to loading directly into railroad cars are the lack of opportunity to clean the coal and the heavy track required. Then, too, it is often impossible to build a track from the railroad switch to the grade of the coal. Where the plant layout calls for a tipple, contractors' narrow-gage equipment is the most satisfactory to use. With two 14- to 18-ton dinkeys each hauling 15 four-yard dump cars, a loading shovel can be served at a distance of two miles from the tipple. An extra haulage unit of one dinkey and 15 cars should be kept in condition for use in any emergency that may arise.

The use of a tipple on a stripping plant is almost a necessity in the preparation of coal. Even with great care on the part of the shovel runner, bottom rock is occasionally loaded. Through the use of the tipple and picking table all impurities can be removed.

The increased use of automatic stokers in power plants makes a crushing unit most desirable, and an up-to-date tipple must include a picking table, crusher and slack conveyor. Each piece of apparatus should be equipped with an individual power drive, for should it be necessary to stop the picking table, in order to remove rock, the crusher can be run until emptied. In this way the crusher is not choked nor is it necessary to start it while loaded. The same is true of the slack conveyor.

Pit drainage is important as it is not always possible to obtain natural drainage. This makes necessary the use of pumps. In the choice of pumps there are three factors to be considered—capacity, portability and power. The capacity of the pump is quite important and it should be large. For instance, let us suppose we have a dry pit with the loading shovel descending a dip. A heavy rain falls during the night or early morning, which floods the loading pit. A man comes out with a team one or two hours before starting time, pulls a pump into the pit and has it dry by the time work should begin, or shortly after. This makes possible a full day's run, while if only a small pump is available one or two days' loading is lost because of the wet pit A portable centrifugal pump with a 4-in. suction and 3-in. discharge working against an 80-ft. head has given satisfactory service. This pump was driven by a 15-hp. gasoline engine with a chain drive and friction clutch. A gasoline engine, while a little troublesome at times, is convenient; and with a good gas-engine man on the job is fairly dependable.

The water supply, while one of the most important factors in steam plants, is generally given the least consideration. An undersized pump, with a 2-in. discharge, is generally hastily installed for the stripping shovel. As the shovel travels, the increased pipe friction and the addition of a loading shovel and dinkeys soon overload the pump and a shortage of water is the result. To close down a plant for lack of water because of low-capacity pumps and an undersized pipe line is not only expensive and inefficient management, but it is discouraging and exasperating to the man in charge as well as demoralizing to the working organization. On any stripping work, of one unit, a pump should have a capacity of not less than 60 gal. per min., and two pumps should be installed. Nothing less than a 3-in. pipe line, well buried below freezing, should be laid.

Flooded Coal Mines in Great Britain

The possibility that the Black Country mines will become totally submerged by the rising water has become a matter of grave concern in Great Britain, especially in view of the millions of tons of mineral that will be lost to the nation. In consequence of the heavy rainfall in the last few months and the inadequacy of the pumping machinery following serious breakdowns, a number of collieries were flooded, and it was intimated that several others will be unable to continue operations. Most of the pits in the Tipton district are working short handed, and the longer roads from the shafts have been abandoned. The colliery proprietors are urging government assistance to free the mines of water, but it is feared that any efforts made in this direction will now be too late. The miners' federation, at the request of the local association, is bringing pressure to bear on the coal controller, and local members of parliament are being urged to use their influence. The district has never before been faced with such a dismal outlook so far as the coal supply is concerned.

Preparation of Bituminous Coal—II

By Ernst Prochaska
Benton, Illinois

SYNOPSIS—*The water used in coal washeries must ordinarily be clarified before it is either allowed to run to waste or used for washing again. Various means have been tried for this purpose with varying degrees of success. One important adjunct of all coal washeries should be a raw-coal storage bin. This should be of sufficient capacity to hold one day's supply of coal. Suitable elevators or conveyors must be provided for placing the coal in storage and removing it therefrom.*

THE methods used for the clarification of the wash water and for sludge recovery at washeries have the combined purpose of using the sludge otherwise carried away with the outflowing wash water and of obtaining sufficiently clear wash water to be used over again. The wash water must be cleared to such an extent that a continuous circulation can be carried on, as the use of fresh water, on account of the great quantities required, would increase the cost of washing to a considerable extent. Theoretically the process of clarification should be carried on in such a way that only sufficient fresh water will be required to make up for the loss of water carried away with the washed coal and the refuse, and also that lost by evaporation and leakages.

The methods of water clarification depend entirely upon the nature of the raw coal. Friable coal which shatters in crushing and which contains a great amount of fireclay will require more extensive and carefully designed clarification plants than a raw coal which does not break up quite so fine and which is freer of fireclay.

The oldest and simplest means of clarifying water consisted of large settling ponds in which the sludge was permitted to settle. After one pond was filled up with sludge a new one was installed or the walls of the first one were built up higher. These settling ponds, however, required immense ground space and later on two clearing basins were installed which were used intermittently. If the first basin became filled, the water was run into the second and the sludge removed from the first.

Did Away With Removal of Sludge by Hand

This arrangement, however, required the removal of the sludge by hand. Further improvements were sought by the use of *Spitzkasten,* which permitted a continuous operation. The sludge was withdrawn from the apex of the *Spitzkasten* and carried in a sluiceway to a settling tank out of which the sludge was conveyed by means of a dewatering elevator to the fine-coal bins. The outflow of the sludge from the *Spitzkasten* was regulated by a valve or cock and was hardly ever continuous.

In some installations the *Spitzkasten* were consolidated into one large settling cone similar to the Callow tanks used in ore dressing. One of the first and best arrangements of this kind is the Ramsay sludge recovery tank used in connection with the Robinson washers. To make the process of sludge recovery still more automatic and continuous, narrow and long settling tanks were installed in which slow-moving scraper conveyors or even screw conveyors collected the sludge which had settled out on the bottom of the tank. On the end opposite to the inlet of the dirty water the bottom of the tank was depressed to form a sludge pit or sump out of which an elevator carried the sludge to the fine-coal bins.

None of the installations described in the foregoing brought about a sufficiently perfect clarification of the wash water. The moving conveyors disturbed the body of the water too much to permit perfect settling; the water overflowed too rapidly to drop all of the fine particles and the resulting sludge was too liquid to be used advantageously without further dewatering. The question of an efficient way of handling and preparing the sludge is still far from being solved in a satisfactory manner.

Dorr Thickeners Clear Water Satisfactorily

The most modern type of sludge recovery and water clarification apparatus—one that promises to become an important part of any coal washery—has been borrowed from the ore-dressing plants where it has been used satisfactorily for many years. The use of Dorr classifiers for the coarse sludge and of Dorr thickeners for the fine pulp is coming into favor, and the experience gained with a few existing plants has shown encouraging results. The Dorr thickeners, if properly installed, do clear the water satisfactorily; and the resulting sludge, even if too liquid to be used without further treatment, is removed continuously and automatically in a simple and economical manner.

The theory of the Dorr thickener is based upon correct principles. The dirty water enters the apparatus at the center and the clear water overflows at the periphery. The sludge settles on the bottom of the circular tank and is carried toward the center discharge in the bottom of the tank by means of slow-moving scrapers. These scrapers being located near the bottom of the tank do not in any way disturb the surface of the water, therefore they do not interfere with the settling out of the sludge. The proportion of solids to liquid in the sludge is only limited by the ability of the pumps to carry away the sludge. In actual practice sludge has been made having 56 per cent. of solids to 44 per cent. of liquid. This sludge is dry enough to be mixed with the dried coal coming from the washer.

Little has been accomplished in treating the sludge succesfully; in fact few people have taken this problem in hand. Some washeries spray the sludge while on shaking screens with fresh water, but this is merely done to wash off the adhering fireclay. In most washeries the sludge if recovered at all is mixed in with the washed fine coal without further treatment. Otherwise it is simply thrown away on the refuse dump.

The most feasible way of treating the sludge would be to dewater it on continuous drum-type filters, and if low enough in ash and sulphur mix it with the washed

coal; or if too high in impurities to permit this, to treat the sludge on slime tables.

The sludge disposal is the final process in coal washing. In regard to the general arrangement of a coal washery it must be stated as important that it has always been considered advantageous to eliminate as far as possible all mechanical means for conveying the materials from one unit to the next. The different units should be arranged in such a way that by gravity only, or by the use of the wash water, the materials can be moved through the whole washing plant.

Where washeries are located on level ground this is only partly possible and elevators and conveyors must be installed. In the early washeries the mistake was made of spreading them out in a horizontal direction and installing between each unit a separate elevating device. This necessitated a great number of individual drives, requiring constant repairs, a great number of spare parts and consumed excessive power. For this reason the modern washeries are built with the units arranged vertically, thereby concentrating all elevating machinery at the incoming end of the plant. This simplifies the machinery, condensing it into a few heavy but carefully designed elevators, driven by large motors that can be operated with a higher efficiency than a great number of smaller ones.

Reasons for Installing a Raw-Coal Bin

A raw-coal storage bin by all means should be included in every coal washery, and this should be made as large as possible for the following reasons:

1. Every interruption in hoisting coal will stop the washery if a certain reserve cannot be supplied during such periods.

2. The foregoing holds true for an interruption in the operation of the screening plant.

3. If the operation of the washery is interrupted, the presence of a raw-coal storage bin will permit the screening plant to be run until the raw-coal bin has been filled. Otherwise the screening plant must be shut down and in connection therewith the hoisting of coal must cease and the working of the whole mine must be stopped.

4. A coal mine does not deliver the coal regularly during the whole day. In the morning the hoisting is rather slow and speeds up until the middle of the day. It is apt to slow down toward the evening. For the proper operation of a washery a regular supply of coal is of the greatest importance. A good sized raw-coal bin permits drawing off of some coal left over from the preceding day during the period of slow hoisting and the filling up of the bin when more coal is hoisted than the washery can handle.

5. If on account of heavier hoisting than figured upon or on account of insufficient capacity of the washery more coal is mined than the washery can take, a large raw-coal bin will make it possible for the washery to consume the daily output of the mine by working overtime.

In consideration of the reasons just enumerated, the raw-coal storage bin demands the fullest consideration as it is an important equalizer between the mine, the screening plant and the washery. If it is not possible to build a sufficiently large bin between the screening plant and the washery, it will become necessary to build one or more reserve bins at some convenient place. Conveyors must be installed to carry the coal between these bins and from them to the washery. The different units between the screening plant and washery are the conveyors from the screening plant to the storage bin, the storage bin proper and the conveying system from the bin to the washery.

Location of the Raw-Coal Storage Bin

To arrive at the proper arrangement of the different units it is necessary to form a correct idea of the most advantageous location and elevation between the screening plant and the washery. The following facts must be considered:

The elevation of the screening plant is fixed by the elevation of the railroad track in the loading yard under the tipple. To load the coal directly from the screens into the railroad cars in the most efficient manner the coal should neither be elevated by separate machinery nor should it drop from too high a point. The elevation of the rails under the tipple are the base from which the elevation of the screening plant must be determined. In a screening plant the use of elevators can be easily avoided, but in a washery conditions are different. The coal must pass over a number of different pieces of apparatus and elevators cannot be entirely avoided.

It has been previously stated that modern washeries are designed with the point in view of avoiding as far as possible the use of numerous small elevators and to place the first units of a washery at such a height that the materials can be conveyed either by gravity or in sluiceways with water through the whole plant. On account of this method of construction it becomes necessary to elevate the raw coal from the screening plant to the washery at a considerable height.

Because the raw coal travels from the screening plant to the washery by way of the raw-coal bin it will be necessary to determine how this bin can be located to the best advantage and so as to make the carrying of the coal as economical and efficient as possible. A raw-coal bin of even a few hundred tons capacity requires a heavy supporting structure and therefore it should not be located any higher than absolutely necessary. The conclusion is thus reached that the heaviest elevating should not be done between the screening plant and the bin but between the bin and the washery.

Storage Bin Should Be Close to Washery

Some designs do not show a proper bin at all but only an arrangement to deposit the raw coal on the ground, with maybe a low retaining wall on both sides to keep the coal from spreading too far. These walls can also be used to support the loading conveyors. The coal is recovered from this pile by a conveyor running in an underground tunnel. For the elevation of great quantities and the required uniform delivery steep bucket elevators have proved themselves especially well adapted. Skip hoists cannot be considered, because the delivery is irregular and intermittent.

For these reasons it is advantageous to locate the raw-coal bin close up against the washery at the ground level. If we now consider that the coal is delivered from the screens at a slight elevation above the track level, and that the top of the raw-coal bin, on account of its required large capacity, is at a much higher elevation, a normal arrangement of the units between the screening plant and the washery will be as follows: Elevating or conveying machinery to overcome slight differences in height between the screening plant and

the raw-coal storage bin and elevators to overcome a considerable difference in height for feeding the washery from this bin.

Scraper conveyors are well adapted for medium grades and short distances. Their construction is simple and they have large capacity with relatively small power consumption. Belt conveyors are also advisable because they carry the smaller sizes of screened coal efficiently. The question to be solved is, which of these two types of conveyors fulfills the conditions to the best advantage?

Belt conveyors are theoretically well adapted for this purpose. The delivery chutes from the screens deposit the coal upon the belts in the best possible manner. The hoppers under the screens act as equalizers and permit uniform loading of the belts. The discharge of coal from the belt into the bin is carried on easily and the coal is transported without degradation. But on the other hand belt conveyors are rather expensive and the belts require frequent renewals.

Scraper conveyors are comparatively cheap, quite durable, and the separate parts can be easily and cheaply replaced so that they are better adapted for rough treatment. But they grind up the coal so that the choice between the two types of conveyors depends a great deal upon the nature and size of the material to be conveyed. Soft friable coals require belt conveyors, especially if the small sizes are of little value. To a hard coal that does not shatter much or to a coking coal where fines are not objectionable, scraper conveyors will be better adapted. But the scraper conveyors use more power than the belt conveyors so that the cost of energy is another consideration that must be taken into account in making the proper selection of the most economical type of conveyor.

Conveyors Transport Material Through Washery

Scraper or belt conveyors are not only used for the filling of the raw-coal bin but are also employed for the conveyance of the different materials through the washery, and especially for the filling of the washed coal bins, which are usually arranged in a series of separate bins set in a row. To fill these bins by means of scraper conveyors it is only necessary to put in openings provided with sliding gates in the bottom of the conveyor trough, at the proper points.

Belt conveyors can be easily equipped with trippers, which will permit the discharge of the coal at any point, or fixed discharge stations can be built into the conveyor. The trippers can be either hand-operated or they can be made automatic and self-reversing. By locating movable stops on the track rails the coal can be discharged either over the whole length of the bin or over any part of it. For bins which are located at right angles to the general flow of material, shuttle conveyors can also be used to advantage.

Which one of the arrangements should be employed depends entirely on the type of the bin. Generally speaking, belt conveyors on account of their light weight and their adaptability to almost any condition are to be used for long distances and for fine coal if it is not too wet. For coarse and wet coal and for short distances scraper conveyors are to be preferred. For short horizontal conveying, shaking conveyors of the Marcus or Zimmer type can also be used to great advantage.

If the raw-coal bin is included within the main washery building the same material is used in the construction of both units. This is either timber, steel or reinforced concrete; in some rare cases, cast iron. Raw-coal bins are built either rectangular or round. Rectangular bins are more expensive in construction but have a greater capacity per square foot of ground space occupied than have circular bins. Rectangular bins permit also a more perfect arrangement for loading and unloading apparatus than do round ones, especially if the necessary capacity increases.

The capacity of the raw-coal bin depends upon the output of the mine and should be at least as large as the daily production. Bins with a capacity of 4000 tons have been constructed and some of the latest designs show bins with 6000 tons capacity.

The mechanical appliances for supplying the washery with raw coal are of the greatest importance. The continuous and regular operation of the washery depends entirely on a steady coal supply; therefore, the strictest specifications should be applied for the design and construction of these appliances.

The capacity must be fully equal to that of the washery. It must be considered that elevators handling large tonnages require large, heavy buckets. On account of the size of the weights to be hoisted and the height to which the coal must be elevated, failures of the chain are disastrous and repairs become difficult and take up much time. For this reason it is preferred to use in large plants two elevators.

Importance of Reliable Elevator Operation

On the other hand the general arrangement and the space available permit the installation of only one raw-coal bin. This makes the installation of more than two elevators almost impossible on account of the lack of room at the bottom of the bins. The conditions at the discharge end of the elevators are similar.

As a usual thing only one unit is provided to receive the raw coal, and economic reasons demand the concentration of the flow of coal through the washery. Therefore we must seek absolutely reliable operation of the elevators. This can only be obtained by using the best of materials, by ample dimensions of the carrying members and by the best workmanship. First cost cannot be considered if we take into account the increase in cost of operation caused by repairs and interruptions.

But even with all these precautions it is advisable, whenever possible, to have a complete spare elevator on hand. In case of a wreck or a collapse of an elevator repairs take a long time, and for this reason a spare elevator ought to be in place for immediate use.

If these precautions are required for continuous operation, there remains still the necessity for a regular and uniform supply. This is of the utmost importance for the efficient working of a washery. On account of the existing conditions, which require the elevating of coarse-grained material at a steep angle to a considerable height, absolutely continuous discharge can hardly be accomplished. But the continuous bucket elevator comes nearer to fulfilling the conditions than any other apparatus.

Bucket elevators are used in coal washeries for various purposes. The most important of these are the following: Supplying the washery with raw coal; dewatering the washed coal and elevating it into the washed coal bins; supplying the rewash jigs; dewatering the sludge; dewatering the secondary product (boiler house coal) and elevating it to the boiler house

coal bin; dewatering the refuse and elevating it into the refuse bin.

The design and construction of elevators depend upon the material to be handled. Most of the elevators are constructed with a two-strand steel-link chain. The chain links and the connecting bolts and rods ought to be fabricated out of the best medium carbon machinery steel. Small elevators have flat links, but for heavy elevators links with upset ends are to be preferred. Under ordinary conditions and for dewatering elevators, buckets are fastened to the chain at every other link. For raw-coal elevators buckets are provided at every link, making it a continuous bucket elevator.

Buckets are made from steel plates, securely riveted to the end plates and provided at the top edges with stiffening bands. Wide buckets have also a stiffener in the middle to prevent bulging out of the sides. The ends of the buckets are fastened to the sides with angle iron or, in some instances, the ends are made of malleable iron. Malleable-iron buckets or those pressed from one piece of steel plate are seldom used. Dewatering elevators have buckets with sides and ends made out of perforated plates. The size of the perforation must be in proportion to the size of the coal handled.

The elevator chains at the top are carried over sprocket wheels or head drums. On the lower end foot drums are universally used. Square, hexagon and octagon drums are employed, depending on the pitch of the chain links. Octagon drums can be used with short pitch chain, whereas those of long pitch require square drums. The pitch of the chain links varies from 8 to 18 inches.

Mechanical Details Are Important

The take-ups are generally placed at the foot of the elevator and only on small elevators are the take-ups placed at the top. Head and foot drums are either made of steel or have steel wearing plates. The chains are guided between angle irons which ought to be protected by wearing plates. To prevent a reverse or running-down motion of the elevator in case of a break, holdbacks are sometimes used.

Elevators are usually driven through a train of gears or by a sprocket or silent chain drive. Belt drives should not be used on account of the danger of slipping. The gear wheels should be of steel while for heavy elevators manganese steel gears ought to be specified.

The framework supporting the chains may be made of steel for the raw-coal elevators, but for dewatering elevators timber frames are to be preferred. The head and jack shafts ought not to be supported on the elevator frames, but on a separate supporting structure. This is advisable in order to facilitate repairs and to keep the gears in better alignment. The size of the bucket elevators varies considerably. The elevators for heavy tonnage are massive and heavy, and must therefore run slowly in order to prevent rapid wear. Dewatering elevators also must operate at a slow speed to permit the draining out of the water before the buckets reach the discharge point.

Dewatering elevators must be inclined to such a degree that the water running out of one bucket will not drip into the one next lower. Raw-coal elevators could be installed vertically, but this arrangement would require too much room at the head as well as at the foot end. The inclination of a raw-coal elevator depends entirely upon the room available. The speed of raw-coal elevators ought not to exceed 100 ft. per minute while dewatering elevators should not be run faster than from 50 to 60 ft. per minute. The maximum capacity of elevators in coal washeries is about 200 tons per hour.

(*To be continued*)

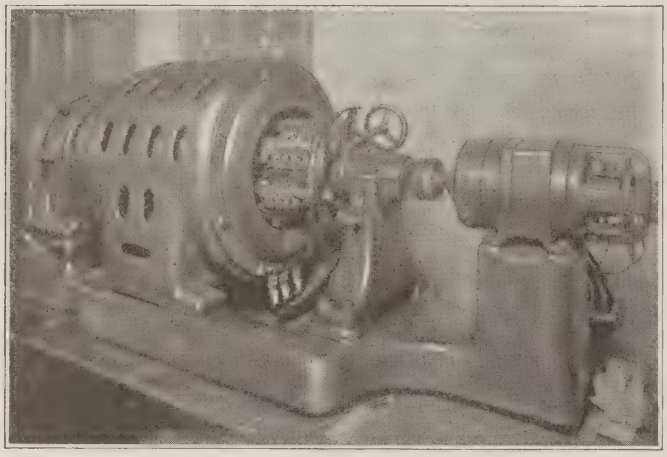
Legal Department

Exclusive Sales Agencies—A contract by a coal-producing company granting another company an exclusive agency for the sale of its output impliedly binds the agent corporation to dispose of its entire output so far as reasonable effort permits. (Kentucky Court of Appeals, Cassidy Coal Co. vs. North Fork Coal Co., 208 Southwestern Reporter, 769.)

Mine Engine as Part of Realty—Where a mining company installed on mining property owned by it an engine weighing 25,000 lb., with a flywheel 12 ft. in diameter, and embedded in a heavy concrete foundation, the engine passed under a subsequent deed of the real estate, as a part thereof, there being no attempted reservation of title to it in the deed. (Alabama Court of Appeals, Lewis vs. Mable, 80 Southern Reporter, 690.)

Pennsylvania Workmen's Compensation Act—A miner dying from inhalation of noxious gases in a mine while obtaining tools is to be regarded as having died from an accident occurring in the course of his employment, entitling his dependent relatives to an award under the Pennsylvania Workmen's Compensation Act, although he had been warned against going to that part of the mine. (Pennsylvania Supreme Court, Gurski vs. Susquehanna Coal Co., 104 Atlantic Reporter, 801.)

Mining Lessee's Timber Rights—A lease of coal lands, granting to the lessee the right to such trees not more than twenty inches in diameter one foot above the ground as might be needed in mining operations, should be construed as applying the diameter limit to the time of cutting, and not as authorizing cutting of trees of that size at the time the lease was made but exceeding the twenty-inch limit at the time of cutting. (West Virginia Supreme Court of Appeals, Raleigh Coal and Coke Co. vs. Mankin, 97 Southeastern Reporter, 299.)



No Liability for Injury to Employee—A mine tracklayer stepped in between two motors to obtain a drink of water from a bucket on one end of one of the motors, although he could have safely and conveniently stood at one side in a clearance way. Not knowing of this man's presence between the motors, one of the motormen attempted to move his motor, but when the brakes were released it rolled back toward the other motor, for want of contact with the trolley wire, and the tracklayer was crushed between the motors and killed. Held, that the mine operator is not liable; there being no actionable negligence through failure to take proper precautions for the safety of decedent. (Kentucky Court of Appeals, Komonyi vs. Consolidation Coal Co., 206 Southwestern Reporter, 883.)

Rights of Coal Corporation Stockholders—An entryman on public coal lands, being unable to pay the price required by the Government, induced three other persons to organize a corporation, to which it was proposed to transfer the entries in exchange for stock. It was agreed as to the proportions in which the stock was to be distributed. Held, that other stockholders cannot recover from the three promoters on the theory of an improper stock distribution to the latter, where the transaction resulted in a profit to the corporation, and all the stock was worth at least par by reason of the lands so conveyed to the company. It is immaterial that the promoters may have reaped greater profits than other purchasers of shares in the corporation. (Utah Supreme Court, Robertson vs. Draney, 178 Pacific Reporter, 35.)

Coal Mine Ventilation Motors*

By H. W. Chadbourne
Schenectady, N. Y.

IN COAL mining it is necessary to keep all passageways and working places in a healthful and safe condition for work. To accomplish this there must be maintained a circulation of fresh air that will dilute, render harmless, and sweep away the noxious gas produced by the breathing of man and animals, the burning of lamps, the condensation of powder smoke, the decay of timber and other organic matter, the gases occluded from the coal faces and the fine coal and slack. Also, if gasoline mine locomotives are used, their exhaust contains additional gases to be diluted and swept away. Not only is the oxygen of the air consumed in the operations

REGULATING SET FOR MINE FAN MOTOR

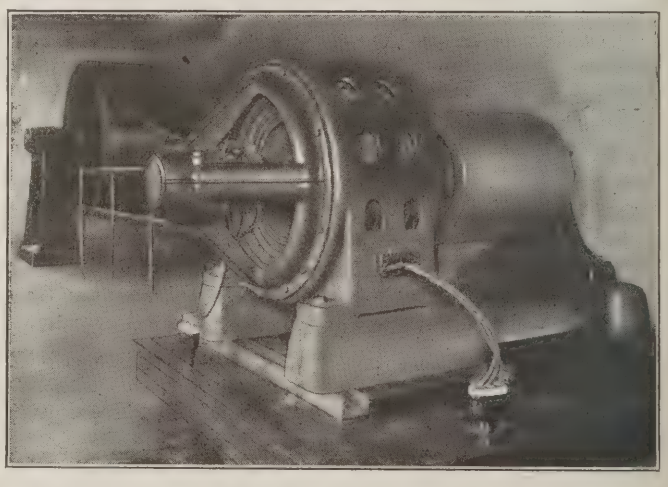
performed in a mine, but a portion is also absorbed by the freshly exposed faces of coal.

There is always an unequal pressure on the air in a mine. This is caused by the difference in temperature of the air inside and outside the mine. This pressure forces air through the passages and workings. The volume of air passing through the mine varies directly with the pressure and inversely with the resistance of the air passages.

Although this method may be suitable for small non-gaseous mines, it is rarely used. Some of the objections to its utilization are that the air pressure varies with the external air temperature. The direction of pressure may be reversed from winter to summer and at intermediate times the pressure will be light or even non-existent, and may vary with the force or direction of the wind. The amount of this natural pressure can be calculated for any given difference of air temperatures, and thus the volume of air at any time be determined.

A furnace is sometimes used to raise the temperature of the up-cast air so that it will be lighter than the down-cast air. This gives more pressure and insures the air always traveling in the same direction. The chief point to be considered is the correct size of furnace. This type of ventilation should not be used in gaseous mines, and in some cases it is prohibited by law.

There have been a number of mechanical methods tried for ventilating mines. Among these might be mentioned: The wind cowl by which the wind pressure on the surface is brought to bear effectively upon the mine air-ways, the waterfall, the steam jet, and the fan or blower.



Mine ventilation fans are of two types, the disk fan and the centrifugal fan, with both of which all mining men are familiar.

The matter of fan speed is an important one. A small fan at high speed may give the same pressure and volume as a large fan at lower speed. There are, however, a number of conditions which make it desirable to have a variable-speed fan. For a given fan with a given size outlet the pressure varies nearly as the square of the speed, the volume directly as the speed, and the power required as the cube of the speed.

There are some conditions where a constant amount of air is necessary 24 hours a day all the year. For this constant-speed work, the standard induction motor is perfectly adapted. It may be remote-controlled if necessary, and requires no attention except to the oiling system; and that only at long intervals.

The choice as to whether a squirrel-cage or phase-wound rotor is used depends on the size of the motor and on the capacity of the transmission line and power service to supply the maximum peak requirements. Generally speaking, squirrel-cage motors should be employed up to about 200 hp., and phase-wound or slip-ring motors above that capacity.

When a mine is in the early stages of development only a small ventilating capacity is required, but later as the workings grow more air is necessary. Also there are times when because of falling roof or other blockades in the air passages a higher pressure is desir-

MOTOR DRIVING VENTILATING FAN

able with a smaller volume. Under these conditions an adjustable-speed fan is desirable and almost necessary. It is therefore the usual practice to use fans of low or moderate speeds, arranged for increased speed when required.

For adjustable-speed motors one naturally thinks first of direct current. The characteristics of a direct-current motor are well suited for adjustable-speed fans, and a large number of such installations have been made. These motors, however, require attention to the

*Abstracted from "Ventilation of Coal Mines," in *General Electric Review.*

commutators, and brushes and the transmission of direct current is not economical except for short distances. Therefore alternating-current motors are used almost entirely.

There are a number of methods for adjusting the speed of alternating-current motors. The first and simplest utilizes the standard induction motor with slip rings or phase-wound rotor and external resistance in the rotor circuit. This motor starts with a small current input and for a given resistance in the rotor circuit it runs at constant speed for a given fan load. As the fan load rarely changes except because of a change in speed, any speed or fan output desired may be obtained by varying the resistance.

The principal objection to this system is that it is inefficient. For instance, for half-speed operation, the power exerted upon the air will be the cube of ½, or 12½ per cent. of full load; but there must be dissipated an equal amount in the resistance plus the losses in the motor itself. Thus an efficiency of less than 50 per cent. is actually obtained. In spite of this low efficiency, however, a large number of these motors have been and are being installed for this class of service.

There are a variety of different dynamic regulation methods which can be employed. Under rheostatic control the energy from the rotor circuit is dissipated as heat. In the dynamic methods this energy is put back into the line. The most common of these systems is that of a regulating set. This arrangement gives exceptionally good operating characteristics, together with high efficiency and power-factor. Its only objection is the additional first cost of the set.

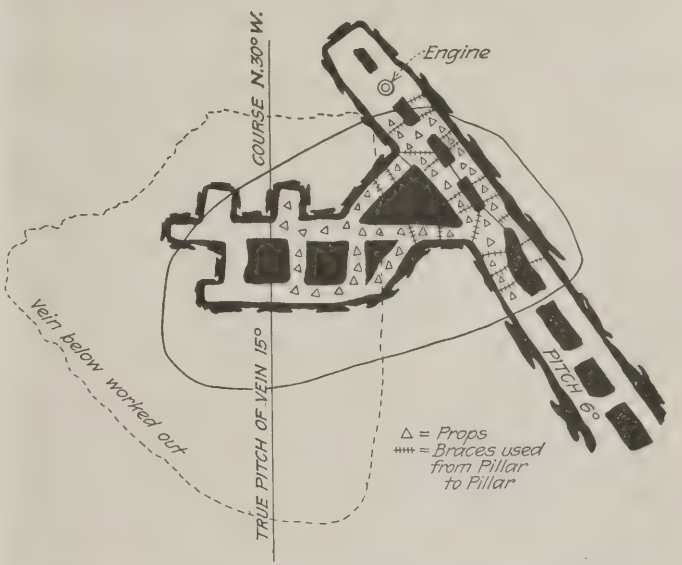
For fan motors of 300 hp. or less, a brush-shifting motor gives a simple, efficient and easily operated machine. This motor is started, its speed changed and even reversed by means of shifting the brushes. With a certain brush setting no torque is developed, and under this condition the motor will not start even if the line switch is closed. The brushes are shifted by a worm gear and handwheel to obtain the desired speed. This type of motor gives stable operation for fan service down to 70 per cent. below synchronism.

Cannel Coal in Texas

What is possibly the largest body of cannel coal in the United States, if not in the world, lies on the Rio Grande about 25 miles above Laredo, Tex. The outcrop of this coal can be traced for many miles in the bluffs along the river in Webb County to a point at which it swings northward into Uvalde County. The coal has been mined for many years at Santo Tomas and more recently at Darwin, or Cannel, and Dolores. It occurs in two principal beds, about 90 ft. apart, both of which are being mined. The beds range in thickness from about 2 ft. to 2 ft. 6 in., and are fairly persistent. For many years they have supplied a large part of the coal used on the railroads in southern Texas and the adjacent part of Mexico.

This coal is of geologic interest because, although it lies in rocks which elsewhere in Texas contain only lignite, it is a bituminous coal. It has the qualities of a cannel coal; it contains a large amount of volatile matter, or gas, and it yields oil by distillation—about 50 gal. of oil to the ton of coal. It contains more nitrogen than any other coal in the United States.

At most places the roof of the coal is poor and requires considerable timbering, and as no trees grow in Webb County this requirement adds considerably to the cost of mining. At each of the mines in this district there is a huge dump of clay, either removed in mining the coal or derived from the shale that forms the roof.



The coal of this field is described in a bulletin entitled "The Santo Tomas Cannel Coal, Webb County, Texas," by George H. Ashley, issued by the United States Geological Survey, Department of the Interior, as Bulletin 691-I.

A Sudden Mine Squeeze Arrested

By J. R. Thomas
Plymouth, Penn.

A squeeze is looked upon by mining men as a difficult problem to handle. Especially is this the case when a squeeze occurs in a bed where the seam underlying it has been worked out. The illustration shows the workings of a section of a mine where a sudden squeeze occurred, and as the bed underneath was worked out within the area shown by the dotted line, many reasons existed to support the belief that it was impossible to save the workings from caving in, or falling into the bed below.

When this squeeze was discovered the first thing done was to temporarily support the roof in the plane

SECTION OF MINE WHERE SQUEEZE OCCURRED

and plane airway with a row of substantial props. Then it was noticed that the props were getting loose, which necessitated their being recapped. It was deemed advisable, therefore, to try and support the roof from the bed beneath, but it was found that it was impossible to get into this at the proper point. The next thing done was to use good strong braces from pillar to pillar, as indicated by the small triangles in the drawing. After the first three pillars had been braced firmly, the squeeze seemed to settle a little. The braces were then used on the pillars, as shown in the sketch, and the workings allowed to stand awhile. It was noticed that the braces were taking weight, as they were bent.

After the workings had stood for a few days the work of reopening began. As the props and braces were removed, double timber of ample size was set and the bed beneath flushed to offer insurance for the prevention of a similar occurrence. The workings at present are still in operation, and everything is quiet.

Progress in Utilizing Pulverized Fuel*

SYNOPSIS—*Many reports received from users of pulverized fuel vary widely in tone, character and enthusiasm. Too much emphasis has been laid upon "heat balances" and by far too little on "cash balances."*

PULVERIZED (or powdered) coal has actively engaged attention for the past five years. Last year we all laid off from studying such things as pulverized coal to do our share in attending to the case of a combination in Central Europe that threw a monkey wrench into the gears of world progress with the idea of revamping things terrestrial to suit their particular kultur scheme. The boys went at the job so hard and earnestly that most of them have not really stopped yet.

The progress report now offered, therefore, will on account of the unusual conditions which have existed consist of a summary of some results, comments and suggestions. These are offered solely with the idea that they may bring out pertinent frank discussion and constructive criticism on an interesting engineering subject. All deeply appreciate the earnest work that has been done thus far to advance the art of burning pulverized coal by both manufacturers and those interested in effecting steam economy. There are many things about pulverized coal that we are satisfied with. There are some things that we are not satisfied with.

It is of the utmost importance that accurate analysis of this subject be made in order that progress may proceed along correct lines. The exact truth of the matter is what is wanted, as no one is so badly fooled as he who fools himself. And now, on the eve of a new advance in world progress, seems a good time to take an inventory.

As railroad interest in pulverized coal at this time lies principally in its value as a steam producer, the subject will be considered from that angle only. To date five different American railroads—the Atchison, Topeka & Santa Fe, Chicago & Northwestern, Delaware & Hudson, Missouri, Kansas & Texas and New York Central—have successfully operated during test periods individual locomotives equipped for and burning pulverized coal. These tests were all made under regular service conditions, and have demonstrated that locomotives burning pulverized coal will meet the train-handling conditions imposed by the different classes of service. None of the locomotives tested is in service at this time, it being necessary in most instances on account of war activity and demand for power to remove the pulverized-fuel equipment and discontinue the experiments.

Requests for information on results obtained from the tests made on locomotives were kindly complied with. The following points from replies received are of interest:

a. A carefully conducted test between two engines of the same class, one burning pulverized coal and the other hand-fired, showed that a saving of 23 per cent. in fuel burned could be made by burning pulverized coal. The main difficulties encountered were the slagging over of the flue sheet and burning out of the brick arch. The slagging was largely overcome by an air jet to blow off the slag accumulations. A number of burner arrangements were tried, but it was found impossible to overcome the rapid burning out of the brick arch. The cost of replacing the arch brick largely overcame the saving in fuel. The delay to locomotive, replacing arch brick, was also a decided drawback.

A comparison of total costs of hand-firing versus pulverized-coal firing on the locomotives tested, which include cost of pulverizing, cost of handling, cost of arch maintenance, interest and depreciation, showed the hand-firing to be the more economical.

In fairness to the pulverized coal it was thought possible to design a firebox that would eliminate such troubles as burning out of the brick arch and show an advantage in favor of the pulverized coal.

b. Burning pulverized fuel was quite satisfactory, furnished all the steam that was wanted with splendid control all the time, burning 60 per cent. anthracite and 40 per cent. bituminous, the bituminous being necessary to increase the volatile.

The question of economy is quite another thing, and unless a poor or byproduct coal can be purchased at a price that will absorb carrying charges, operation, etc., of a pulverizing plant and not exceed the price of a satisfactory lump coal, it should be given careful thought. There is no saving in the quantity of fuel used when pulverized, in fact the difference is in favor of the lump coal. Pulverizing costs between 45 and 50 cents per ton.

c. The burning of pulverzied coal in a locomitive was quite an easy proposition, and with us was very satisfactory. The only difficulties were with the drying, pulverizing and handling of the coal, and also the danger in connection with it. In case of a large number of engines being equipped to burn pulverized coal, were the plant to be blown up, burned or otherwise made inoperative, the locomotives would be tied up until the plant was in service again.

One foreign railroad, the Central Railway of Brazil, has made marked progress in burning pulverized coal. The following quoted from data kindly furnished by the Pulverized Fuel Equipment Corporation, will be of interest and give an idea of what has been accomplished:

d. The Central Railway of Brazil, after considerable investigation of pulverized-fuel-burning locomotives in this country, on account of the high cost of imported coal and inability to utilize the low grade domestic coal by burning it on grates, decided to install pulverized-fuel equipment for locomotive and stationary boiler purposes.

From a study of the coal measures in the southern part of Brazil during 1904-06 it was concluded that the native coal was unsuitable for economic use. Later, during 1915-16, at the direction of Dr. Miguel Arrojado Lisbona, then director of government-operated railways, an investigation was made of the use of pulverized fuel in the United States with the result that the Central Railway of Brazil decided to install a 15-ton-per-hour fuel-preparing and coaling plant and a stationary boiler equipment at Barra do Pirahy, an engine house and shop terminal about 65 miles north of Rio. Plans and specifications were prepared and installation was made. Arrangements were also made for the equipping of 250 existing and new locomotives, and since 12 ten-wheel type and two consolidation-type locomotives have been newly built and so equipped by the American Locomotive Co. and put into regular use.

The first locomotive put into service was No. 273, one of the ten-wheel type, which on its first round trip between Barra do Pirahy and Entre Rios ran a distance of about 110 miles, in freight service, in 7 hours 11 minutes, maintaining an average steam pressure of 172 lb. with maximum

*Progress report submitted by pulverized fuel committee to the International Railway Association. Committee consisted of W. J. Bohan (chairman), H. T. Bentley, H. B. Brown, R. R. Hibben, D. R. MacBain, J. H. Manning, H. C. Oviatt, John Purcell and L. R. Pyle.

working pressure of 175 lb., and with the pulverized-fuel-burning equipment working perfectly.

Steam pressure was easily maintained at all times with a clear stack with no difficulty whatsoever from ash or slag in the firebox or flues.

The first *official* run with the Brazilian native coal pulverized was made on Sept. 9, 1917, with a special train that transported Dr. Wenceslao Braz, President of the Republic of Brazil, and his staff. Ten-wheel type locomotive No. 282 handled the President's special train from Barra do Pirahy

ANALYSES OF FUELS USED

Name	Kind	Moisture	Volatile	Fixed Carbon	Ash	B.t.u.
Jacuhy	Bituminous	6.10	28.40	45.70	19.80	10,851
Santa Catharina	Bituminous	12.60	36.00	42.10	9.00	10,259
S. Jeronymo	Bituminous	3.00	31.00	39.30	26.70	9,565
Cascapava	Lignite	19.00	36.00	19.20	25.80	5,249

to Cruzeiro, a distance of about 90 miles, and during the greater part of the trip President Braz remained in the locomotive cab and fired the locomotive, on which the steam pressure was fully maintained throughout, without any smoke.

The Central Railway of Brazil locomotives equipped with pulverized fuel are operating in fast passenger, mixed passenger and freight, and freight service, and all are giving excellent results.

The results of tests recently conducted with Brazilian native coal and lignite may be stated as follows: (1) Distance traveled during trials was 118 miles. (2) Boiler pressure during trials remained almost constantly at 175 lb., which is working pressure.

The only difficulty met with has been in instructing the enginemen, who were not acquainted with this method of combustion, and for this purpose an illustrated instruction book has been issued to each man.

Only by adopting this pulverized-fuel system has the problem of the utilization of Brazilian coal, which cannot be burned practically or economically on grates or in retorts,

PERFORMANCE DATA

Fuel Name	Fuel Kind	Fuel B.t.u.	Quantity Burned Per Trip, Net Tons	Evaporation Lb. of Water Per Lb. of Fuel	Ash Found in Firebox and Pan, Lb.
Jacuhy	Bituminous	10,851	4.19	7.2	176
Santa Catharina	Bituminous	10,259	3.5	7.1	176
S. Jeronymo.	Bituminous	9,565	5.42	7.1	198
Cascapava....	Lignite....	5,249	4.41	7.3	220

or utilized to good advantage for the production of producer gas, been solved, and the development of the native coal fields of the country is now in process through the establishment of steamship and railway means of transportation from the mines, and in the actual mining developments.

Something like 200 pulverized-fuel installations on stationary plants are in operation throughout the United States, comprising central power and lighting stations, street railway power stations, power stations of various manufacturing industries, railroads, mining companies, smelters, sugar refineries, office buildings, hotels, schools, laundries, etc. These plants are reported as successfully burning all grades and classifications of anthracite, bituminous, sub-bituminous and lignite coals in the pulverized form.

The following are quotations from various replies to inquiries sent to different parts of the country asking for results obtained from stationary plants:

a. From an engineering company handling pulverized-coal equipment:

The advantages which can be obtained by using pulverized coal in plants where the quantity of coal used daily is sufficient to obtain a low cost of preparation is marked. In the first place, where pulverized coal is used, it is necessary that the boilers be equipped with combustion chambers suitable for the maximum amount of coal that will be burned to operate the boilers at maximum rating. The reason for these large combustion chambers is to eliminate refractory troubles entirely. The obtaining of good combustion is secondary to furnace life, and therefore this feature of design of the combustion chamber is the most important one to consider.

All kinds of coal can be burned satisfactorily in pulverized form regardless of quality, and there are no limitations to boiler capacity due to poor qualities of coal fired. Economy of operation is therefore far beyond that obtained by burning coal in lumps with any other kind of equipment, and from results already obtained there is no question in our minds but that pulverized coal is the coming fuel and that burning coal in pulverized form will shortly become the standard method of burning on account of the high economy obtainable.

b. Remarks in connection with a test made at an eastern experimental plant burning anthracite silt:

All claims made as to efficiency to be obtained were demonstrated to the satisfaction of everyone present, and it was remarkable how they made it possible to control the temperature in the ash pan. As you are aware, this has been the source of considerable trouble when removing the slag, but I wish to state no trouble in this connection was experienced at this test. The evaporation of 8 lb. of water per pound of coal was remarkable in view of the fuel used.

The proximate analysis of the fuel used in this test was:

	Per Cent.
Moisture	0.5
Volatile	8.5
Fixed carbon	78.0
Ash	13.0
B.t.u.	12,000 to 13,000

c. The folllowing is a log of test of a 300-hp. boiler burning a low grade of Pacific coast sub-bituminous pulverized coal exclusively at one of the power stations of a large West Coast traction, light and power company. (Figures shown in column A.)

The committee also obtained a log of test of two 512-hp. Stirling boilers located at one of the stations of another large railway, light and power company in another city in the same territory burning a similar grade of coal with Sanford Riley stokers. (These results are tabulated in column B for comparison.)

	A (Pulverized Coal)	B (Sanford Riley Stoker)
Type and capacity of boiler	B. & W. 300 hp.	Stirling 512 hp.
Duration of trial	14 hr., 7 min.	10 hr.
Temperature of feed water, deg. F.	185	150
Water evaporated, lb.	148,240	238,099.47
Temperature of steam, deg. F.	412	.....
Steam pressure, lb. ga.	112	.....
Factor of evaporation	1.1	1.17
Weight of coal, lb.	24,540	.....
Evaporation per lb. of coal as fired	6.05	5.175 (dry coal)
From and at 212 deg.	6.67	6.054 (dry coal)
CO_2 flue gas	13	8.8
B.t.u. raw coal	8,061	6,974 (as fired)
B.t.u. pulverized coal	9,688	9,650 (dry)
Efficiency, per cent	67 (details not given)	
Kind of coal	Centralia-Tono	*Chehalis-Superior
*Approximate analysis	*As fired	*Dry Coal
Moisture	27.50	....
Volatile combustible	35.53	49.08
Fixed carbon	27.98	38.65
Ash	8.9	12.27
Sulphur	1.07	1.53
B.t.u.	6,974	9,650

NOTE.—Attention is called to the comparative closeness of results obtained considering comparative B.t.u. of the two dry coals.

d. Personal visits to pulverized-coal-burning plants installed in a large office building, a high school building and a large laundry in this city (a Western city) developed that at both the office and the high school buildings trouble was being experienced with moisture in the powdered coal, and that one case of explosion had occurred at the laundry

due to careless operation. Engineers in charge of these plants expressed the opinion that oil and powdered coal at present prices in that locality were about a standoff.

e. From a company handling pulverized fuel apparatus:

Supporting data will show you that past experience has demonstrated that for locomotive use the economy of pulverized fuel has been proved, and that the items of auxiliary cost, trouble with moisture reabsorption and slag are things of the past and not of the present or future.

f. From a cement company (Southwest) which has burned powdered coal in its stationary boiler plant to some extent:

We have for years used pulverized coal in our kilns and therefore are fully equipped for drying, pulverizing and conveying this fuel in powdered form. Our coal when dried contains less than 1 per cent. of moisture, and we have provided against damage and therefore have never had an accident on account of spontaneous combustion. I may state further that our limited experience leads us to believe that while there are some difficulties to be overcome, greater efficiency may be obtained from the use of coal in the powdered form, under properly equipped stationary boilers of suitable type, than can be obtained from the use of such coal in any other form.

g. From a large power and light company (Middle West):

We do not experience any slagging, brickwork or explosion trouble. Difficulties are being encountered due to moisture in the coal, but whether it is a reabsorption or not we cannot definitely state. We are making arrangements to determine this by changes in our drying plant. When this is completed we will have eliminated one uncertainty.

h. From a large smelting company (Rocky Mountain district):

In the following report of boiler test is shown the type and size of boilers used and the efficiency obtained in our power house boiler No. 8. Only No. 7 and No. 8 boilers are now equipped with pulverized-coal burners. But it is expected that we will equip the other boilers to burn this fuel in the near future. The power house boilers are used as auxiliary to the waste heat boilers in the reverberatory furnace flues; so that the load factor on these boilers is quite variable and the efficiency is correspondingly low.

The coal is dumped from the cars into coal bins; then on belt conveyors it travels past Ding magnetic pulleys, which take out all iron, onto rolls where it is crushed; into Ruggles coal dryers; up elevators to Raymond five-roller pulverizers; fan elevators and screw conveyors; to powdered coal-storage bins over furnaces to be fired. Eighty per cent. of the powdered coal will pass through a 200-mesh screen. At first considerable trouble was experienced with explosions. These difficulties were overcome by study of conditions. In drying the coal the temperature of the dryer and amount of air was regulated according to amount of moisture.

With moisture from 5 to 10 per cent. the temperature used is 110 to 130 deg. C.
With moisture from 10 to 15 per cent. the temperature used is 120 to 140 deg. C.
With moisture from 15 to 20 per cent. the temperature used is 130 to 145 deg. C.

Explosions are sometimes still experienced in the elevator that takes the coal from the dryer, but explosion doors are provided and the explosions do no damage. The pulverized coal in the storage bins sometimes ignites spontaneously, but these bins are air-tight and the smoldering fire is soon extinguished by cutting off the coal supply to the bin on fire, and feeding out the coal in the bin.

i. From a southwestern railroad:

I am not in a position to give you very much of a report for the past year, as our stationary boiler plant that uses pulverized fuel has during the past year been compelled to use a considerable amount of oil, this on account of breakdowns and other troubles, and also the mixing of oil and powdered coal.

The manufacturers have for some time, in fact almost all winter, been changing, overhauling and remodeling their equipment, and on two boilers we have had very little service on this account. I am not going to give you any figures as to the cost of using pulverized coal at our plant for the reason that our pulverizing and drying plant has not sufficient capacity to properly take care of the demands upon it, and this, you understand, requires more labor than would otherwise be necessary, hence the cost is greater and would not be a fair comparison. We have, however, kept the plant going on pulverized coal most of the time, but it has been a forced proposition.

The foregoing summary you will note has been collected from widely different sources. It is representative of the results obtained with different fuels throughout the United States and also is representative of the enthusiasm of the manufacturer of pulverized fuel apparatus and the reality of the man who must justify his engineering opinion for power installations by increased economies sufficient to justify the expenditures made and who must primarily keep the industry in which he is interested operating at full capacity. The following conclusions may be deduced:

The development of the art of burning pulverized coal during the past two years has shown marked progress in that the experimental work done and tests made, although still incomplete, have demonstrated the

EVAPORATION TEST ON 330-HP. TYPE K-19 STIRLING BOILER BURNING POWDERED COAL

1.	Date of trial	Sept. 6, 1918
2.	Duration of trial	6 hr. 48 min.
	Make of boiler	Stirling
	Sq.ft. heating surface	3,297
	Rated horsepower	330
	Volume of firebox	1,782 cu.ft.
	Number of burners	1
	Average Pressures	
3.	Steam pressure in boiler, by gage	153.5 lb.
4.	Absolute steam pressure	166.28 lb.
5.	Atmospheric pressure, 25.95 in.	12.78 lb.
	Average Temperatures	
6.	Of external air	77 deg. F.
7.	Of fireroom	80 deg. F.
8.	Of steam	366.6 deg. F.
9.	Of escaping gases	514 deg. F.
10.	Of feed water	64 deg. F.
	Fuel	
	Kind	Wyoming lignite
	State	Powdered
	Analysis of Coal	
		As Fired / As Received
	Moisture	2.83 per cent. / 19.2 per cent.
	Volatile	42.77 per cent. / 34.3 per cent.
	Fixed carbon	49.90 per cent. / 42.5 per cent.
	Ash	4.50 per cent. / 4.0 per cent.
	B.t.u., per lb	11,849
11.	Total amount of coal fired	13,821 lb.
12.	Dry coal fired	13,430 lb.
13.	Combustible fired	12,808 lb.
14.	Total coal fired per hour	2,032 lb.
15.	Dry coal fired per hour	1,975 lb.
16.	Combustible fired per hour	1,884 lb.
	Quality of Steam	
	Percentage of moisture in steam	3.3 per cent.
	Quality of steam	96.7 per cent.
	Degrees of superheat	0.
	Water	
	Total water fed to boiler	99,679 lb.
	Total water actually evaporated	96,390 lb.
	Total water evaporated from and at 212 deg. F.	115,547 lb.
	Water fed to boiler per hour	14,659 lb.
	Water actually evaporated per hour	14,175 lb.
	Equivalent water evaporated per hour from and at 212 deg. F.	16,992 lb.
	Lb. of water fed to boiler per lb. of coal fired	7.21
	Lb. of water evaporated per lb. of coal fired	6.97
	Lb. of water evaporated per lb. of dry coal	7.18
	Lb. of water evaporated from and at 212 deg. per lb. of coal	8.36
	Lb. of water evaporated from and at 212 deg. per lb. of dry coal	8.60
	Lb. of water evaporated from and at 212 deg. per lb. of dry combustible	9.02
	Average heat in coal 11,849 B.t.u per lb. of coal as fired— Heat produced per hour	24,077,168 B.t.u.

Heat required to evaporate a lb. of steam as discharged from the boilers = 0.967 (1195.1 — 32.0) + 0.033 (338.7 — 32) = 1124.7 + 10.1 = 1134.8.

Total heat given to the boilers per hour = $14,659 \times 1134.8 = 16,635,000$ B.t.u.

$$\text{Efficiency of boiler} = \frac{16,635,000}{24,077,000} = 69.1$$

$$\text{Horsepower developed} = \frac{16,635,000}{33,479} = 497.$$

$$\text{Per cent. of horsepower rating developed} = \frac{497}{330} = 151 \text{ per cent.}$$

apparent soundness of the principle of burning coal in a finely divided form in suspension, and that the complete commercial success depends upon the further careful working out of such details as the correct determinations of proper fineness of the various grades of coals, and economical and efficient methods and apparatus for preparing, storing and transporting the pulverized coal to the stationary plant or locomotive furnace.

It has not been clearly established that coal ground to the extreme fineness and dried to the extent recommended by most of the supporters of pulverized coal best meets the conditions of the practical user operating under widely diversified conditions. The tendency to explosion and spontaneous combustion, which is always present in coal of this character, should be eliminated entirely if possible to do so. The tendency of reabsorption of moisture in containers and transmission piping in stationary plants and at coaling stations of railroads will always be a problem in climates having extreme variations of temperature and humidity.

Experiments to determine if thoroughly air-dried coal ground to the fineness of, say, coarse granulated sugar and burned in suspension in specially designed furnaces will not produce greater over-all economies should be made.

Individuality of Locomotive Should Be Considered When Using Powdered Coal

Further, in so far as the use of this kind of fuel on locomotives is concerned, it seems advisable to give more careful consideration to the individuality of the flexible steam locomotive as it exists today. Regardless of the objections which may be raised at this time to the locomotive stoker, the fact remains that it is a usable and practical device capable of producing economical over-all results. Much improvement may be expected in the locomotive stoker during the next ten years, and it is without the realm of possibility that a pulverizing and stoking device might be arranged that would prepare any grade of coal on the tender and deliver it to the firebox in the pulverized form, thus eliminating all of the expense incident to preparing and transporting pulverized coal from a central plant. The same thing would also apply in a modified form to a stationary plant.

As is frequently the case with large engineering projects this one has some too-enthusiastic promoters. Much ill-advised engineering work and experimenting has been done and some snap conclusions have been rendered without careful analysis of the problem and without the essential laboratory work necessary to the establishment of fundamental facts.

Some hurriedly prepared and conducted tests with incomplete and inadequate facilities and equipment have been made, particularly on locomotives on busy railroads during periods of heavy traffic movement. Tests of any kind conducted at such times always create prejudice, due to the fact that they are more or less of a nuisance. Such tests are frequently void of results, not only from lack of preparation and facilities, but also because employees cannot give them proper attention. In fact, the tendency of employees during such busy times is to do all they can to get rid of tests as quickly as possible. For these reasons also adverse opinions and doubt about pulverized fuel prevail in the minds of many.

It does not seem that we are using the laboratories of our great universities to a sufficient extent. Many of these universities have thoroughly equipped laboratories, and they always have many eager and bright young men who, guided by capable faculties, could and gladly would not only thoroughly thrash out all of the technical questions and lay the foundation for reasonably operative devices before making field applications, but the opportunity for so doing would vastly increase the practical knowledge of these students and better prepare them for the field of work they may select, by giving them an insight into the practical side of their work and thus produce increased man efficiency which would be of mutual value to both the young men themselves and the industries that employ them.

It is particularly noticeable in the reports of pulverized-fuel tests received by this committee that practically all dealt with fuel economy only and by means of a deluge of figures and "heat balances" conclusively proved fuel economy to everybody's satisfaction. Not enough has been said about "cash balances." All industries are operated for the purpose of paying dividends and maintaining economic balance. In this respect conclusive evidence is lacking about pulverized coal, at least in so far as this committee has been able to develop after careful inquiry. This has been disappointing. May we hope for some reliable statistics in the near future that will dispel all doubt that now exists on this important matter?

There is little or no question about the ultimate practicability, efficiency and economy of burning coal in a finely divided form, both in stationary plants and locomotives. To develop this fact to a practical conclusion requires thorough coöperation of both manufacturer and user and it is suggested that in view of the immense supply of bituminous, lignite and other grades of coals of various characteristics peculiarly adapted to the pulverized method of burning, that as soon as business conditions again adjust themselves, the railroads, with the assistance of manufacturers and universities, make the necessary conclusive and exhaustive tests and develop the fixed principles of methods and apparatus necessary to successfully meet the urgent demands for more economical consumption of coal. This is not a question of self-interest on the part of either manufacturer or particular industry. It is one of national interest and urgency.

After a mine explosion many miners and officials from other mines offer their services. The number of such volunteers is generally so large during the first four or five days following a disaster that the services of all the men cannot be profitably utilized, but they as well as those whose services have been accepted must necessarily be fed. For this purpose a commissary and mess should be established. The commissary should be placed in charge of the manager or superintendent of the store and the mess in charge of an experienced cook who should be furnished from the commissary the necessary stoves, utensils, dishes, etc., to enable him to supply wholesome food for the men doing the rescue and recovery work. The mess should be assigned to some unused building or part of a building or to a tent. The kitchen should be kept separate from the mess room, and all persons except those engaged in preparing and serving the food should be excluded from it.—*Rescue and Recovery Operations in Mines.*

Original Pocahontas Coal Field

Among the pioneer coal and coke operations of the original Pocahontas coal field of West Virginia is the Houston Coal and Coke Co., whose plant (as it appears today) is shown in the accompanying panoramic view. The store and office of this company is opposite the Elkhorn station on the Norfolk & Western R.R. The Houston plant has expanded wonderfully under the management of the family whose name it bears, and the leadership of T. E. Houston. In the '90's a modest tipple occupied about the site of the present modern plant for preparing and loading coal. At that time Mine No. 2 of this company was opened up and preparations were actively prosecuted to make the operation what it is today—the largest single shipping plant of the old Pocahontas field.

With the increase of mine opening, greater accommodations were provided for workmen, more coke ovens were built and every facility added to handle large tonnage. The Houston tipple is located between the two mine openings, and the coal is moved from mines to dump over surface roads by motors. The location of these tramroads is clearly indicated by the grade and the line of trolley poles. Extensive sidings for loaded and empty mine cars are provided at the tipple, 50 loads being accommodated at one time. The narrow valley at this point is so completely taken up by the plant that it would seem as though "standing room only" were left.

The long line of inactive ovens calls attention to the days when the Norfolk & Western R.R. distributed cars for the transportation of coal in proportion to the number of coke ovens possessed by an operation. This was in the days when Pocahontas coal was making its way in the world, and often slack would have been a drug on the market were it not converted into coke. In the '90's new plants were sometimes developed and 100 or more coke ovens built solely to secure railroad cars. The ovens might be built of the cheapest materials and never be fired up; in a short time grass grew on the oven-clay filling, and later the firebrick disintegrated and the ovens caved. In the light of present-day practice this would seem to be quite a waste of capital.

It was during these days that an operator started a mine near the town of Pocahontas and decided to combat the policy which was then in vogue in the field. No coke ovens were built at his plant, and when the mine and tipple were about ready to ship coal he notified the Norfolk & Western of his intention to ship shortly and asked for a railroad siding and cars. This request being refused, teams were secured and coal from his plant was dumped at the railroad freight depot. This operator claimed that the railroad company was a common carrier of freight and should receive transportation when presented. The situation was an interesting one. In the course of time conditions in the field changed and the coal became one of the most famous fuels on the continent. In 1916 about 19 millions tons of coal were shipped from McDowell County, West Virginia.

The appearance of the Houston oven plant reflects conditions throughout the field. In 1916 there were 9730 beehive ovens in McDowell County, of which just 6269 were not in use; only about one-third of the ovens were making coke. While Pocahontas slack is in demand among byproduct coke oven operators who use it to mix with certain high volatile coal, many authorities claim that this noted fuel should never be used for any other purpose than raising steam, asserting that not a pound of Pocahontas coal should be made into coke. The Houston interests are represented at other points in the Pocahontas field, one plant, the operation at Keystone, closely approaching the mines at Elkhorn as regards annual shipments. The aggregate tonnage of the Houston plants shipping Pocahontas No. 3 coal amounted to 1,139,100 in 1916. As the operators of these noted Pocahontas mines look forward to the exhaustion of their properties, other coal investments are often made in territory adjacent to the original field. The Houston people have valuable properties in the newer Pocahontas field as well as in the Thacker territory.

PLANT OF THE HOUSTON COAL AND COKE CO. AT ELKHORN, W. VA., IN THE HEART OF THE

Nova Scotia's Submarine Coal Mining Problem

At the extreme northern part of Cape Breton County, Nova Scotia, the coal measures dip toward and extend under the sea at low angles. The beds are affected by no important structural breaks or faults, according to "The Coal Resources of the World."

Mining operations beneath the sea have shown that the coal seams are continuous beyond the points where, from a consideration of the structure, faults might be expected to occur. From the undisturbed condition of the land areas it might be expected that the undersea area is also undisturbed and that a large portion of its coal, to a limited distance from shore, will utimately be utilized. The coal seams throughout the whole field are generally quite uniform in thickness.

Mining operations are being extended under the sea at several points in the Sydney field. Some of the mines have workings extending over a mile from shore; at a distance of a mile some small rolls parallel to the coast were passed through. These are the only disturbances in the regularity of the measures, and it therefore seems possible, according to the authority previously noted, to extend the workings everywhere to the limit of haulage and ventilation. In an estimate of the amount of coal, the limit for probable reserves is fixed at three miles from the shore and that for possible reserves at five miles. Figuring on this basis and including seams of one foot or over to a depth of 4000 ft., the actual coal reserves of Cape Breton County are 1,027,911,000 metric tons; this calculation is based on actual thickness and extent. An approximate estimate places the probable reserves at 4,064,357,000 metric tons.

The Sydney coal field extends for a distance of about 30 miles in an airline along the northeast shore of Cape Breton Island. Recently a question of considerable interest, both from an engineering and a legal standpoint, has arisen in relation to the undersea extension of this coalfield, says an editorial in the *Canadian Mining Journal*. The coal practically can be attacked only from the shore end of the deposit and along a line 30 miles in extent. The system under which the undersea coal areas have been leased for the mining of this coal has permitted the blanketing of some leases by other leases.

A situation has now developed which calls for some remedial action by the Province, which is the lessor of the coal areas. It is the intention of the local government to enact legislation which will correct the existing condition. The lease plan of this coal area as it exists today shows a checker board of conflicting and interfering leases that absolutely prohibit the extraction of the submarine coal by any methods which would commend themselves to a mining engineer or operator interested in the best, the most complete and the most economical extraction of the submarine coal.

Probably when the early leases were given out to lessees the extent of the coal field was not known; its extension under the sea may have been given little if any thought. Furthermore, the lease lines were drawn arbitrarily to further disconnected and oftentimes conflicting private and corporate interests during many generations. The last and least consideration that has governed the layout of the submarine leases has been the preservation of the coal field for economical operation. It has been aptly stated of the lease plan that, like Topsy, "it growed." No person living is to blame for the tangle, but the remedy is within the power of those who administer the coal areas as stewards for the people of Nova Scotia.

The Cape Breton coal field is a unique deposit of coal, at least as far as the American continent is concerned. Its exact submarine extent is not known, but enough of its probable extent is known to state confidently that the field has a long future if it is conceived as one comprehensive mining proposition. It is a field in which one operation by unwise or careless management may depreciate the value of the whole or even impair the accessibility of a considerable part of it.

ORIGINAL POCAHONTAS COAL FIELD; ON MAIN LINE OF THE NORFOLK & WESTERN RAILROAD

A memoir on "The Coal Fields of Eastern Canada" was written for the Canadian Federal Department of Mines some three years ago by F. W. Gray. In this report is summarized the mining laws of the Province in relation to the unworked submarine coal field; the state of affairs revealed by the Fuel Controller of the Province was noted, and Mr. Gray stated that it was the obvious duty of the present generation "so to prosecute the work of extraction as not to imperil the accessibility of the remaining submarine coal." This is precisely what the present arrangement of the submarine leases will not permit of being done. If the existing lease lines are adhered to, the greatest single asset of the Province will be imperiled.

In discussing the limitations to working the submarine coal field in the memoir just referred to, Mr. Gray predicted that the cost of mining would be the first limiting factor to make itself felt. Therefore, no artificially difficult conditions of extraction should be unnecessarily imposed on mining coal from submarine territory. This would cause the limit of profitable mining to be reached sooner than would otherwise be the case, and the Province would the earlier lose its revenues and all the other advantages that accompany the production of coal.

If previous experience could have governed the leasing of submarine areas, then it would have been realized how different submarine mining is to ordinary land operations. In the latter case mine openings can be located at many points on the surface, but access to submarine areas is limited to certain parts of the shore. Therefore, it would have been seen that no submarine leases should have been granted, unless their accessibility was secured by the terms of the lease itself.

The present outlook for coal in Nova Scotia seems to be uncertain in view of the fact that this industry is admittedly going to have sufficiently hard work to keep its head above water without the addition of unnecessary duplication of expenditure and effort, and without the totally unnecessary addition to the cost of extraction which adherence to existing lease lines will inevitably cause. The truth is, says the *Canadian Mining Journal*, that the whole submarine coal question should be thoroughly reviewed. A map should be made of the whole coal field showing the existing workings, the outcrops, the location of the faults and folds, and all lease lines. Due consideration should be given to the facts disclosed by soundings at sea, the nature of the sea bottom, data concerning the superincumbent strata, the position of the coal seams and the probable extent of the submarine coal field. This information should have been available for reference on a government map, especially as the whole matter is controlled by the Province. Some of the data must have been on hand for many years; a complete land map at least should have been kept up to date. Other information could readily have been added from time to time and a comprehensive view of the whole situation would have disclosed at an earlier date the tangle which now comes prominently to light. But of course hindsight is distinctly better than foresight.

The making of the map proposed would seem to be inevitable. It should then come up for consideration by competent mining engineers who might to advantage practically disregard existing lease lines where they seriously handicap the final working of the coal field as a whole. This plan would necessitate considerable lease readjustment on the part of the owners of the coal (the Province) to satisfy the lessors. However, the conservation of the submarine coal, its protection from inundation, creep, improper mining and the preservation of its accessibility over the maximum period of operation should guide those having the readjustment in hand.

The measure which has recently been passed by the Nova Scotia Legislature regarding coal areas in Sydney Harbor, in which both the Nova Scotia Steel and Coal Co. and the Dominion Steel Corporation are interested, is a fair and reasonable one, according to W. D. Ross, vice-president of the former company. Mr. Ross commented that there is much misapprehension outside of the Province as to the meaning and effect of the act. This legislation is necessary owing to the hopelessly uneconomic location of the submarine leases in the Cape Breton coal field. The act provides that governmental inquiry is to be made by a commission and that on the report of this commission, the Governor may rearrange these areas so that the undersea coal may be systematically mined. The so-called blanket lease of the Dominion company is not to be interfered with, the act only applies to other submarine areas and due compensation is provided for. The governmental investigation and subsequent adjustment of this matter is expected to insure not only to the benefit of the Province but to the principal coal companies involved as well.

TARDINESS

By J. KENVIN
Jeddo, Penn.

Every day in the mines of America I make thieves of honest men.

I steal from employers precious hours, never worked, but paid for nevertheless.

I cause miners to hurry along forbidden haulageways when Death rides a speeding trip bound bottomward.

Outside men caught by habit hurry along forbidden paths or travel on busy planes and trips, risking life and limb to hide their guilt.

Breaker boys in my clutches hurry over dangerous drag lines and under speeding shafting, often meeting with injury or worse.

By these and other means I cause delay and friction in the starting of breakers and the operation of mines, and mar the workday at its beginning.

I am Tardiness. Promptness and Punctuality are my worst enemies.

AT ONE TIME it was considered that waste constituted fine coal, the largest piece of which passed through a $\frac{3}{32}$-in. mesh. This fine coal or culm approximated 7½ per cent. of the total output. At the present time coal passing through a $\frac{3}{64}$-in. mesh is either utilized at the plant, shipped or stocked for future use.

Haulage Capacity of Locomotives

By E. Steck
Hillsboro, Illinois

MINE superintendents often order a haulage locomotive of certain weight because they have seen such a locomotive in operation in some other mine, and hauling an amount of coal which they desire to haul in their own mines. If the locomotive fails to haul this amount of coal, or if its armatures burn out, the blame is often laid at the door of the manufacturer. The reason for this failure may be any one of a number of causes, as the haulage capacity depends on the following factors: Weight of locomotives, type of tires, speed of haulage, horsepower rating of motors, grades, weight of pit cars, type and condition of wheels on pit cars, condition of track, length of haul, number of cars per trip loaded, number of cars per trip empty, number of trips a day. In the foregoing it is assumed that the proper voltage is supplied to the locomotive.

The maximum drawbar pull of a locomotive in pounds is equal to one-fifth of the weight of the locomotive for iron wheels, and one-fourth for steel-tired wheels. This is on the basis of a clean, straight rail. Beyond this, excessive slipping of the wheels will occur.

The horsepower developed by the motors equals:

$$\frac{\textit{Tractive effort} \times \textit{speed of locomotive in feet per minute}}{33000 \times \textit{mechanical efficiency of locomotive.}}$$

For example, take a 10-ton locomotive with steel-tired wheels and a speed of 7 miles per hour:

$$\textit{The tractive effort} = \frac{2000 \times 10}{4} = 5000\ lb.$$

$$\textit{Speed in feet per minute} = \frac{5280 \times 7}{60} = 616.$$

Assume the mechanical efficiency as being 90 per cent., then

$$Hp. = \frac{5000 \times 616}{33000 \times 0.90} = 103\ hp.$$

The practice among locomotive builders is to furnish on standard equipment 10 hp. per ton, or on a 10-ton locomotive two 50-hp. motors.

The horsepower rating of this type of motor is on the basis of a rise of temperature of 75 deg. C. after one hour's operation at full load. In other words, if the locomotive under discussion were loaded to develop a maximum tractive effort at the end of one hour, the motor temperature would show a rise of 75 deg. C., which would mean, in a room temperature of 70 deg. F., a motor temperature of $70 + \left(\frac{9}{5} \times 75\right) = 205$ deg. Fahrenheit.

For a day's run the square root of the mean square values of the current for the various cycles of operation for the two 50-hp. motors must not exceed 75 amp. per motor; or, in other words, the average horsepower must not exceed 34 per cent. of the normal rating of the motors.

The drawbar pull to move pit cars varies greatly with the condition and type of car wheels. This variation may be from 15 to 50 lb. per ton. A conservative average is 30 lb. per ton. On grades 20 lb. per ton additional is required for each per cent. of inclination independent of the friction of the wheels.

Again referring to the 10-ton locomotive with a maximum tractive effort of 5000 lb., the total drawbar pull on various grades is as follows:

Drawbar pull on level $= 5000 - (30 \times 10) = 4700$ lb.
Drawbar pull on 1 per cent. grade $= 5000 - (30 \times 20)\ 10 = 4500$ lb.
Drawbar pull on 2 per cent. grade $= 5000 - [30 + (2 \times 20)]\ 10 = 4300$ lb.
Drawbar pull on 3 per cent. grade $= 5000 - [30 + (3 \times 20)]\ 10 = 4100$ lb.
Drawbar pull on 4 per cent. grade $= 5000 - [30 + (4 \times 20)]\ 10 = 3900$ lb.
Drawbar pull on 5 per cent. grade $= 5000 - [30 + (5 \times 20)]\ 10 = 3700$ lb.

The number of tons this locomotive will haul on the different grades is as follows:

Level, $\frac{4700}{30} = 157$ tons.

1 per cent. grade, $\frac{4500}{(30 + 20)} = 90$ tons.

2 per cent. grade, $\frac{4300}{[30 + (2 \times 20)]} = 61$ tons.

3 per cent. grade, $\frac{4100}{[30 + (3 \times 20)]} = 46$ tons.

4 per cent. grade, $\frac{3900}{[30 + (4 \times 20)]} = 35$ tons.

5 per cent. grade, $\frac{3700}{[30 + (5 \times 20)]} = 28$ tons.

Assume that a pit car weighs 2500 lb. and has a capacity of 4 tons, the number of cars and tons of coal this 10-ton locomotive is capable of hauling will be as follows:

Grades	*No. of Cars*	*Tons Coal per Trip*
Level	30	120
1 per cent	17	68
2 per cent	12	48
3 per cent	9	36
4 per cent	7	28
5 per cent	5	20

The foregoing tabulations give the haulage capacity of the 10-ton locomotive on the basis of one hour with a maximum permissible rise of motor temperature. The continuous capacity of the locomotive would be only 34 per cent. of that given in the tabulation. The actual cars per trip must be calculated from the sequence of grades, the number of empties and the number of loads per trip, as well as the number of trips per day. The square root of the sum of the mean square values of the currents must not exceed, in this particular case, 75 amp. per motor. The current values can be determined by placing an ammeter on the locomotive and taking readings for a round trip, and then taking into consideration the number of trips per day. The graphic ammeter is the best variety to employ because the time during which the various current values flow through the motors of the locomotive may be readily calculated from its graph.

Attention should be paid to curves, as the track gage on them should be increased, especially where long wheel base locomotives are employed. Otherwise the wheels will bind and reduce the haulage capacity of the locomotive.

National Coal Association Holds Meeting at Chicago

The National Coal Association meets in perfect harmony after several months' experience in co-operation. A banner in the meeting room states that "The big idea of coöperation is education." The members are fully committed to that form of education as far as it is embodied in open prices, but there are not a few who still halt at accepting Dr. Garfield's appeal for open costs of production.

EVERYTHING at the meeting of the National Coal Association, held in Chicago May 22 to 24, moved quietly and according to schedule, but the session did not lack for enthusiasm nevertheless. The only unexpected discussion was one relative to the use of Mexican oil. That matter may, in the future, cause no little anxiety in the minds of the members of the association. Some are already keen to its possibility as a menace.

The meetings of the association were held in the Congress Hotel, and no one was excluded, the regular press table being well filled and plainly in evidence. The association lays all its cards on the table. It is not purposing the violation of any laws. Never was an organization more careful of its ground. From the rostrum its attorney watches every move like a hawk, ready to counsel the meeting should it in its proceedings vary a hair's breadth from the straight and narrow way of strict legality.

An address of welcome was made by H. H. Merrick, president of the Chicago Association of Commerce. He declared that the three essentials of life were air, water and coal. Chicago, he said, had them all, and it was certainly true that Chicago had more than its share of rain and smoke-laden air while the members were in session.

Suspicious of Proposed Amendments

Proposed amendments to the charter aroused the suspicions of one of the West Virginia delegations, of which Tom Lewis was a conspicuous leader. Mr. Lewis sought to delay action on the amendments until they were printed and duly considered by all present. Later, when it appeared that the voluminous amendments might be expressed by laymen in a few words, and would be dismissed by them in a few minutes as entirely inconsequential, Mr. Lewis and his friends withdrew their opposition. By that time the amendments were in the print shop and shortly thereafter were ready for distribution. They were carried unanimously. The only purposes of the change were (1) to lift bodily out of the charter the requirement that there be 37 directors, (2) to put that provision in the by-laws and (3) to give the general secretary the title of vice president with all the powers of the general secretary intact.

The word "secretary" has a progressively attenuating value. The word "general" placed before it does not attain the object sought, which is to name the real executive officer of the organization. Some institutions have added "general manager" to the title, but "vice president" is, by and large, considered the better term. Hence J. D. A. Morrow, the permanent central ganglion of the National Coal Association, becomes "vice president in receipt of pay."

President Wheelwright's report confined itself in the main to a recital of the cheerful acquiescence of the coal industry in the work of the war. General Secretary Morrow, with business-like and fluent oratory, took up the questions confronting the association in some detail. He said that the war revenue legislation was written with an eye to the manufacturing industries and not to mining. Washington was not blind to the fact and was prepared to recognize the difference as taxables between the two types of industries.

He spoke a good word for open prices—open covenants openly arrived at. The reports of prices as received did not, he admitted, cover the whole country. Some associations had not gathered their forces together properly since the war and could not at that moment collect price data. Others doubtless viewed the propriety of open prices with some doubt. What data had been collected did not include all the sales made. The collection of such data would probably never be complete.

Open Market Prices Inspire Confidence

But even in the Stock Exchange there are "wash sales" which disguise the real market movement. There are sales made out of the exchange regarding which no word is obtainable. Nevertheless the Stock Exchange prices receive almost universal recognition. They inspire confidence. No one feels, when he buys or sells on their indications, that he is being, or is even in risk of being, dealt with unfairly.

They shed a light on the conditions of industry, and a similar light is shed by the open price in the coal market. It is about the only large basal industry which has till the present been content to grope in the dark. Given a dark room and a cry of fire, the members of the august assembly he was addressing might be found bleeding and mangled as a result of a wild, haphazard rush for the exits. But given a light, all might be expected to find their way out by the devious paths that led to the adjacent room.

Similarly, given the cry of low-price sales in a market unlighted by published quotations, the mine operators might expect to find themselves, as they had often found themselves before, struggling in the dark and injuring one another in the hope of finding an exit from their financial troubles by the dangerous and mutually harmful way of unfair competition. The darkened way is over the chairs and the lighted way, the way of the corridor.

He said the operators would sit up nights trying to save a fraction of a cent in the cost of production and then with the return of the working day would give away several times that fraction in the first contract that they made.

In the afternoon it was decided that a portion of each company's assessment be allocated to payment for the

Digest, so as to make that publication subject to second-class rates. The railroad-relations committee recommended in its report that legislation be passed forbidding the assignment of cars in return for the acceptance of railroad orders.

One of the star features of the meeting was the report of the cost-accounting committee as read by Thomas T. Brewster. As it is printed and will go to all the members, it is not necessary to consider it here. Taking issue with some of the recommendations of the Federal Trade Commission, the committee relies on the commission to show again the broad judgment that it has always exhibited in the past and to modify its stand wherever a good case can be made for the change.

The foreign-trade committee did not report. It is understood that the committee of 27 formed a subcommittee of three which went to Washington and obtained a promise that 1,500,000 tons of shipping would be allocated to the coal industry in the last quarter of the year. This is regarded by some as entirely inadequate, and indeed it will be so unless the allocation is permanent and not for one trip only. The reason for the delay of the report was the absence of Thomas F. Farrell, the chairman, who was at the coast to welcome his returning soldier-son.

The credentials committee reported that 28 associations were represented and that 21,009 votes would be cast out of 21,050.

On the following day Dr. H. A. Garfield, United States Fuel Administrator, made a valedictory address in the spirit which has endeared that official to the coal industry. He admitted that the Administration had made some mistakes. He said he did not blame the N. C. A. members for criticism so long as it was constructive criticism. This was, he added later, his valedictory. Some would be glad he was saying goodby; to such he could only say that he was glad to say goodby to them. This was said in Dr. Garfield's most winning manner. Not even those at whom it was aimed would take offense. But he intimated these persons were few in number and that he was more than pleased that after the years of trial he was a welcome guest to the counsels of the National Coal Association and a good friend to those engaged in the production of coal.

Dr. Garfield declared himself of the opinion that owing to the increased size of corporations we could no longer do business as in earlier days. Some corporations are now so large that they employ as many men as there were people in the thirteen states at the foundation of the republic. Some corporations are as big as some governments in 1776. The same rules could not, he believed, be applied to such mammoth corporations as had been adequate when dealing with partnerships and individuals. The day of "laissez faire" he felt was passed. Hereafter it was not a question whether government shall interfere, but how much.

The coal industry has grown in public respect. When the war started the railroads, recognizing that coal would keep, kept it on the sidetrack. Coal, we have learned, is the food of industry. We have recognized at last that the army is but the cutting edge of our nation, whereas industry is the real force by which the nation triumphs.

Strategy is no longer confined to the foughten field. In a large sense it runs back behind the lines. The narrow pass which decides a campaign may not be crossed by men of war. It may be merely some congested point of traffic or a shortage of bunker space in a harbor. The lack of supplies that its existence causes may not be felt at once, and it may be some months later when the issue at the strategic point decides the campaign.

Dr. Garfield added that, fortunately, owing to the stimulus given the industry in production campaigns, our production grew progressively larger as the war advanced, whereas in other countries it progressively declined.

He urged the industry to hold firm to cost accounting and warned the mining men that if the public believed it was not getting a square deal it would not be satisfied, and the industry would then have to settle with radicalism. He advocated open production costs, so that the United States might know that the coal business is properly conducted. There are three parties in interest—the consuming public, capital and labor. They may well sit apart in their counsels but they should, before final decision, sit together. The cost of production should be as well known to the Government as the cost of living.

The report of the finance committee was as follows:

	Expenses Year Ending Mar. 31, 1919	Expenses Estimated Year Ending Mar. 31, 1920
Executive	$43,576.68	$43,000.00
General office	33,987.02	31,064 46
Information	116,762.58	40,648.56
Traffic	10,886.00	9,700.00
Accounting	3,391.64	7,400.00
Legal	14,501.20	12,000.00
Market information service	1,833.68	21,000.00
Equipment	1,162.94	2,000.00
Total	$226,099.74	$167,313.02

In the afternoon the new president, Harry N. Taylor, took the chair. He declared his determination to give a square deal to the multiple interests of the National Coal Association: A. F. Sheldon, president of the Sheldon School, addressed the meeting on "Selling Coal for a Profit." His address was excellent though not strikingly new. He based salesmanship on service. It was at the conclusion of his remarks that the discussion on Mexican oil arose. C. E. Bockus, president of the Clinchfield Coal Corporation, said that the oil could be produced for 19c. per barrel with a labor cost of only 8c. It can be delivered on the coast for from 60c. to 70c. a barrel. Two or three hundred contracts have been placed, to come in effect as soon as the refining plant being erected at Charleston, S. C., is completed. With oil at such prices coal would have to be sold on the coast at $2 or $3 per ton. T. W. W. Guthrie, president of the United Coal Corporation, Pittsburgh, Penn., stated that if coal of equal thermal power to oil were to be delivered to the market it would have to be sold for 20c. per ton to compete on an even basis with oil when freight rates are considered.

The smoker held Tuesday evening was a most enjoyable event, especially an address by an orator named Mallett, of the *American Lumberman.* His epigrams kept the whole party convulsed.

THE FOLLOWING ACCOUNT of an accident furnishes food for thought from several different angles. A motorman left his trip while it was in motion and with the power turned on, and ran ahead to open a door; he fell on the track and was run over and killed by the trip. This man's idea likely was not to save time but rather to avoid the trouble of walking back to his trip. A motor should never be left alone with the power turned on; it would also be well to reflect that an automatic mine door would have avoided the issue altogether.

Liquid-Oxygen Explosives*

The military necessity which compelled Germany to requisition her entire stock of nitric explosives created an emergency which gave liquid oxygen its opportunity, and its development as a mining explosive has occasioned considerable comment.

The explosives now in general use are mixtures or definite compounds containing two essential constituents, a combustible element—carbon—and an ignition element—oxygen. The explosion is the result of the abrupt and violent combination of these two elements. Oxygen is introduced under the form of nitric combination or chlorinated combination, whereas the carbon is in the form of an organic matter. Therefore, in ordinary explosives, the combination of the active elements carries with it a considerable dead weight, constituted by the other elements.

New Explosive the Result of Evolution

This is not the case with "Oxyliquit," for in the latter the liquefied oxygen is put in contact with carbon in a divided and porous form. Under a system of ignition the combination takes place with explosion, and in principle the procedure is perfect. In the evolution of this process, however, which was first invented by Linde in 1895, many difficulties were encountered.

Liquid oxygen is always produced on the spot where it is to be used, as it is impossible to prevent volatilization for very long, notwithstanding all the precautions. It is prepared by liquefying the air, the mixture so obtained of liquefied nitrogen and oxygen being submitted to a partial distillation, which eliminates the larger part of the nitrogen, more volatile than the oxygen. The resulting bluish liquid contains about 85 per cent. of oxygen. A German company exploiting the Linde patents is able to furnish installations giving an hourly output of 23 lb. (10 kg.) of liquefied rectified oxygen.

Containers Used for Transporting Liquid Oxygen

Transportation of the liquefied oxygen from the place of production to the place of utilization, mine or quarry, required a new container. In the laboratory, glass vessels, so-called "Dewar" bottles, having double walls with a vacuum between, have been used for the keeping of liquefied oxygen. These bottles are not closed—on account of the danger of a closed bottle in handling—but, owing to good insulation, the loss of oxygen by evaporation is small. These glass bottles, easily breakable, are neither convenient for wholesale manufacturing nor for use in the workshop, and are now replaced by containers of metal—especially brass and steel—which give excellent service.

The steel or brass bottles do not hold the vacuum as well as those of glass, and the vacuum must be often renewed. To lessen this inconvenience, Dewar inserts porous charcoal between the walls.

By what is known as the Kowastsch method, the liquid oxygen is poured upon lampblack in the borehole. A cylindrical cardboard cartridge is made of the same diameter as the hole, the cartridge containing the lampblack or other porous material rich in carbon. It is closed at both ends with cardboard or cork. Two small tubes of thin cardboard pierce the stopper at the outer end. These tubes serve for the pouring of the oxygen; also for the ignition system (fuse or electric). The cartridge being thus made, a metal rod is inserted in each tube to prevent it being crushed, and the cartridge is deposited at the bottom of the hole, which is then packed with a wad of clay. The metal rods are extracted and the liquid oxygen is poured in through the larger tube by means of an elbow funnel. The gaseous air escapes by the shorter tube, and also the overflow of liquid oxygen when the cartridge is saturated completely. The cartridge is now ready for the firing. The explosion is comparable to that of dynamite.

The Marsit method allows of a more regular working. It is therefore more in use than the other. Here the cartridge is saturated before being introduced into the borehole. To do this the cartridges are immersed in a special vessel of cylindrical shape with double walls filled with liquid oxygen. The cartridges are first exposed for a few minutes to the vapors above the liquid to cool them off, then completely immersed for half an hour. The saturation is therefore complete. When the cartridge is saturated, it is taken out and the ignition system attached as quickly as possible. It is then placed in the borehole, tamped and exploded.

Inconveniences of Marsit Method

The manipulation in this method is far simpler than in the first mentioned. The only inconvenience is the unavoidable delay between the taking out of the cartridge and the placing in the borehole. During the lapse of these few minutes a certain part of the oxygen of the cartridge evaporates. To lessen this loss, and to keep in the lampblack a sufficient excess of oxygen, the walls of the cartridge, which are made watertight, are of corrugated cardboard. No detonator is needed to explode these cartridges, and this is one of the advantages of the new method. All that is necessary is a small primer ignited by a fuse or by electricity.

The principal company manufacturing "Oxyliquit," the Sprengluft Gesellschaft, of Berlin, claims to have delivered each year an equivalent of 10,000 tons of nitric explosives. Even allowing for probable exaggeration, this figure shows how widely this product is used in Germany. Its greatest advantage over other explosives is that it almost entirely eliminates the danger of accidents. The cartridge itself is explosive for about 10 min. only, between the time of its saturation and the time of its ignition. During this time the danger is not any greater than with any other explosives. The result is that in case of a miss it is only necessary to wait half an hour for the cartridge to become entirely harmless, and then one can uncover the borehole without danger. Moreover, all dangers inherent to transportation and storage of the explosive are entirely eliminated.

Some Objections to the Method

The method, however, has its inconveniences, the principal objection being that it is impossible to store liquid oxygen, necessitating the establishment of a liquefaction and rectifying plant at the place where it is used. Also, there is need of experienced hands for a quick charging of the boreholes.

Theoretically the new explosive may claim superiority over others. In practice, however, it gives an explosion hardly equivalent to the most powerful explosives known, common dynamite and gelatin-dynamite.

*Abstract of an article appearing in the January issue of *Compressed Air Magazine.*

Urge Elimination of Waste in Mining and Consumption of Coal

In pointing out the means of remedying wastefulness in the use of energy resources, C. C. Gilbert and J. E. Pogue, of the Division of Mineral Technology of the National Museum, make the following reference to coal:

Coal is the basis of organized life—the home, industry and commerce are entirely dependent upon it. Under the present conditions, it is failing to live up to that responsibility. It is wastefully mined because of unnecessary conditions of competition; it is wastefully distributed as a result of unnecessary transportation to regions already supplied with water power or with coal of a lower grade than that transported; it is wastefully used because the numerous valuable byproducts resulting from burning coal are not recovered.

The wastes in mining may be decreased by considering coal as a public utility and eliminating undue competition, by integrating the mining operations—organizing them to work together instead of in competition. Unnecessary distribution of coal may be reduced by developing water power in favorable regions, and by improving methods of utilizing the large quantities of lower grade coal in the regions where it occurs, doing away with the necessity of hauling high-grade coal to those localities. The waste in utilization of coal may be eliminated by establishing municipal public utility fuel plants to convert coal into gas for heating purposes, at the same time recovering the valuable byproducts, ammonia. benzol and tar. This method of community use of coal will give cheaper fuel, end the smoke nuisance, relieve transportation, and cause the growth of a great coal-products industry, whose ultimate possibilities are beyond the grasp of imagination.

In concluding, the authors reduce the whole energy situation, an extremely complicated subject, to a fundamental basis in which two courses of action on the part of the Government will bring about the proper development of the whole matter.

1. The provision of a common-carrier system for the transmission of electrical energy, which will lead to a balanced development of coal power and water power, and serve as a coördinating influence in the building up of municipal public-utility fuel plants.

2. The application of a constructive economic policy to the production of petroleum, which will largely correct the wasteful methods which are now leading to a premature exhaustion of the petroleum resource.

Foreign trade, despite the relaxation of many restrictions, is still hampered by Government regulations.

Reifkin Sues du Ponts for Commission on Coal Purchases

A suit for $473,750.43 against the E. I. du Pont de Nemours Co. has been filed in the Supreme Court of the District of Columbia by Philip M. Reifkin, formerly of the Bureau of Mines. The amount in question is alleged to be due Mr. Reifkin as a part of his commission while acting as coal purchasing agent for the du Pont company. Mr. Reifkin alleges that between Nov. 15, 1917, and Mar. 31, 1918, at the request of the company, he obtained for them 3,168,100 tons of bituminous coal for a commission of 15c. a ton and 41,950 tons of anthracite coal for a commission of 20c. a ton. He received on account of his claim $9,854.57, and alleges that the company refuses to pay the balance.

Many Coal Companies Paid Unnecessary Taxes to Government

Now that the coal industry is becoming more familiar with the revenue act, it finds that many companies have paid more taxes than was necessary. Since it is held not to be the intention of the law to take money inequitably from those that were undercapitalized, or who made payments through miscalculation, it is believed that arrangements will be perfected to make reimbursements in all such cases. The matter is being presented vigorously to internal revenue authorities at the present time by attorneys for numerous coal interests.

Railroads Trying to Collect Old Accounts

In their efforts to relieve their present financial stringency, the railroads are going to unusual extremes to collect money. They are going over their books and raking up old accounts that had been regarded as impossible of collection. In a large number of cases, freight bills which the consignee has failed to pay, and which cannot be collected, are being presented to the consignor. A large number of suits are being filed in such cases. A considerable percentage of such cases is based on coal shipments.

While the Industrial Board of the Department of Commerce is a thing of the past, due to the refusal of the Director General of Railroads to coöperate with the stabilization program of the Department of Commerce, it is believed that his very obstinacy in this matter will bring the whole question of consolidated purchasing power to an issue.

EDITORIALS

Overwhelming Flood of Money

INFLATION is not necessarily accompanied by high prices, any more than quantities of mines are inevitably associated with large tonnage, or extended lengths of railroad lines with car-miles of transportation.

Mines, at times, lie idle or work irregularly and half-heartedly and the tonnage is low despite the multitude of collieries. Railroads which could carry immense quantities of merchandise may rust for lack of traffic. Similarly, when times are unfavorable any amount of currency and credit may be idle.

But granted there is a demand, the mines produce a flood of coal, adequate railroads will transport endless quantities of goods and the currency will support an unheard-of amount of inflation. That is why we have to fear the flood of money of which the world is now possessed. When we get busy the money will come pouring out upon us. Comparatively idle now, it will be active tomorrow.

We want a little higher price now only for stimulus. In the year coming we may well find it disturbing to our social relations. The war increases will not be duplicated; nor, alas, will the war patriotism. We shall not have the chance to stay the ill feeling that a readjustment may bring with it. For this reason it would be well if we could secure a new dollar such as Professor Fisher has been advocating, a dollar that will be a unit of consumption and based, not on gold values, but on all the elements which enter into our expenditures for living.

Labor is most efficient when times are bad and there is little demand for goods. As soon as times become good the workmen become indifferent and listless. Thus supply is shut off by demand and actually fed by lack of orders. All of which contradicts, in part, the law of supply and demand.

Spectacular Career of Electric Mine Motor

THE electric locomotive for haulage purposes in and around the mining districts has become such a matter-of-fact part of the equipment today that one seldom considers how rapidly it has forged to the front as the dominant system of haulage in the coal mines. The mine operator of this country is quick to appreciate the advantages of improved equipment and there is, perhaps, no better example of this than the spectacular career of the electric mine motor. For example, the number of electric locomotives in use in and around the Pennsylvania bituminous mines had increased from 1300 in 1910 to 2600 in 1916, thus doubling itself in a six-year period.

This same period has witnessed the gradual demise of steam and air locomotives. The steam locomotive underground has shown a gradual but fairly persistent decline in numbers, from 166 in 1910 to 142 in 1916, though it did show indications of recouping its declining fortunes in 1912, when 168 were in use; however, the decline in their use since that time leaves small room for doubt as to the ultimate future of the steam locomotive in the coal mine.

Even the air locomotive, with its reputation for safety in gaseous mines, is apparently suffering the same fate. This type of locomotive apparently reached the climax of its career in 1915, when 168 of these machines were in use, this representing an increase of about 20 since 1910. There was a gradual decline in their use in 1914 and 1915, the number falling off six in each year. But in 1916 there was a sharp decline of 19, making the total in use in that year 137, or twelve less than in 1910.

The history in the anthracite field is much the same, though the decline of the steam and air motor is less evident. The number of electric locomotives has practically doubled, there being 568 in use in 1910 as compared with 1133 in 1916. The air locomotives in use in 1910 numbered 142, this increasing to a maximum of 163 in 1912. This number remained practically stationary until 1915, when there was a moderate decline to 156. The number of steam locomotives increased up to 1915, but the succeeding year showed a very sharp decline; a continuation of this movement can have but one final result.

Nor is this trend confined alone to the State of Pennsylvania. Ohio, with high wage scales, has been quick to adopt any means that might reduce operating charges, and the increase in the number of motors there has been quite as rapid as in the Pennsylvania field. The state report shows 405 electric motors in use in 1909 and 525 in 1912.

The reports from Illinois tell the same story; in 1907 there were only 129 electric locomotives in use in the mines of Illinois, and in 1917 there were 744. Statistics for this state also show the falling off in the use of cable and animal haulage. In 1907 there were 26 mines using cable hauls and only five in 1917. Even the old mine mule has had to give way before his more efficient and economical brother, the mine motor. The reports show that some 27,000,000 tons of coal were handled by 303 mules in the year 1907, and 10 years later there were only 113 left, which handled 9½ million tons.

Figures such as these cannot but bring home to the mine operator the need for closer attention to the mechanical side of his operations. It is only in this way that the economies necessary to meet the aggressive competition that marks the coal industry today can be met. Further improvements in mechanical equipment are necessitating higher grade men as time goes on, and it is not unlikely that the next decade will see the mechanical engineer as an important official at all the larger mining operations.

Operators could well take example from the army in its rehabilitation work. There is no reason why a man who has lost one or more of his members in a mine accident should not be prepared for some job for which his injuries do not necessarily render him unfit.

Other Times, Other Preferences

STYLE changes. First of all, "Any coal so it's bright"; then, "Any coal so it's chunky." Later we began to inquire into its sulphur and phosphorus contents, then into the thermal values. Still later we started investigations into the fusing temperature of ash. We may yet regard content of recoverable nitrogen as the true index of superiority or, perhaps, the quantity of material solvent in phenol or the amount of pyridine extract. As we play new favorites among coal qualities the high places of coal production will change their location. We do not now know whether the type of coal produced in the Pocahontas region or that found in North Dakota will eventually be considered preferable?

The operating revenue of the railroads under the Government administration during the first three months of this year was $1,125,078,000; the loss was $192,000,000, or 17.06 per cent. on every ton hauled. A good beginning for Government ownership!

Is It Safe to Dry the Air Entering Coal Mines?

FOR SOME time English engineers have been considering how best to meet the difficulties of mining coal at great depth. It is claimed that the heat and humidity of the air will be the principal obstacle to be overcome at depth. The remedy suggested is the cooling and drying of the air entering the mine and, if necessary, drying the air at different points in the mine. This operation is common practice in refrigeration establishments. It seems that it is not so much the heat that affects the miners as it is the heat combined with the moisture in the atmosphere. It is well known that if the humidity is low, perspiration takes place freely from the surface of the human body and a man may be fairly comfortable even though the temperature of the air is high. Suffering is caused by the atmosphere being so charged with moisture that perspiration is not readily absorbed.

It has been suggested that modern cold-storage methods be followed as to mechanical equipment to dry and cool air entering mine workings. While overcoming one objectionable feature by this method will not dangerous conditions of another sort be brought about? In some gaseous and dusty bituminous mines in the United States it is common practice to humidify the air and to sprinkle the roadways to keep down the dust. Will not the possibilities of coal dust explosions be increased in some instances by drying the air entering mines?

Pinching the dollar till the eagle screams was well enough during the war. Let the dollar loose now, wherever the expenditure will serve to restore the wastes of deferred maintenance.

Powdered Coal and Its Application

INQUIRIES reaching *Coal Age* concerning the applicability and use of coal in powdered form show that the characteristics and utility of this method of combustion are not thoroughly understood by the average person. The introduction of finely divided fuel into a furnace by means of a strong air blast, and the production there of a flame with intense heat strongly resembling a gas or oil flame, is apparently sufficiently spectacular to take powerful hold upon the layman's imagination.

That powdered coal will burn while in a state of suspension in air has been common knowledge among engineers for many years. Serious attempts to utilize this process on a commercial scale started about the beginning of the present century. Today, after approximately twenty years of experiment, trial and use, the limitations of the process are fairly well defined and accurately known.

A powdered-coal fire is one of great heat intensity or high local or centralized temperature. In certain metallurgical processes this is exactly what is desired. Here the value of the metal treated is large compared to the cost of the furnace. The degree of temperature necessary to fuse the metal is sufficient to ruin the furnace after a certain number of runs, regardless of the kind of fuel used. To such processes pulverized coal lends itself admirably, and is consequently there employed with excellent results.

Difficulty experienced with powdered coal in steam-raising has arisen from the fact that the temperature attained in the furnace is greater than the boiler setting can long endure. Here the process is continuous, and the value of the product (steam) made daily is small compared to the cost of the setting. Frequent renewal of the furnace or its lining is therefore out of the question.

The claim that coal burned in the powdered form yields more heat than similar coal burned on grates is, other things being equal, absolutely false. Any unit, such as one pound or one ton, of any coal contains a definite, determinable number of British thermal units; and no device, contrivance or process of man can change this amount one iota. It is quite true, however, that the definite amount of heat evolved from the combustion of a pound of coal by one process may be more available, or recoverable in larger measure, than that resulting from the combustion of the same pound of coal by another process. Thus, if the coal contains 15,000 B.t.u. per pound, in one case 10,000 B.t.u. only might be absorbed; while in another, say, 12,000 B.t.u. might be utilized. This, however, is a question of heat absorption, not heat generation.

It is probable that much of the misunderstanding and misconception surrounding the utilization of pulverized coal arises from a confusion of heat volume with heat intensity. The average person has no more definite and exact idea of just what constitutes the difference between a British thermal unit and a degree Fahrenheit than he has of the distinction between a watt and a volt. To such a man a high-flame temperature may be quite easily, perhaps naturally, confounded with large heat yield from the fuel.

Workingmen everywhere rejoice when the industry they labor in is attacked for its prices, despite the fact that if their goods are bought for too low a price they must be produced by low wages. Where the prices charged are known to be fair, at least a decent neutrality might be expected. Furthermore, when one knows that a daily paper continually misrepresents one industry—one's own—it is safe to assume that it misrepresents other industries as well. Why therefore credit it?

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

A feeling has been prevalent that the British Columbian plan of advancing wages to accord with increased costs of living by an automatic provision embedded in the contract would not find favor with the mine worker. It is true it was not popular in British Columbia among the workmen, but it is also true that there is in western Canada a degree of unrest unparalleled, and apt to continue unparalleled, here.

In fact, had an automatic clause been introduced earlier it would have done much to delay the progress of sovietism in western Canada. Canada has gorged herself even more gluttonously than have we, with foreigners who do not understand her free institutions, do not know her language or appreciate her spirit. Many of our coal regions were well peopled with Americans before the mines were opened in them. There was thus a basis of Americanism on which to work. The civilization of the people in parts was, it is true, often quite backward. The mountains had shut them in and arrested their development. But they were of our kin; they spoke our language; they were fostered in the same traditions; they revered what we revere. As a result there is always a bedrock of conservatism that cannot be found in every instance in western Canada, where all is newer and where the percentage of foreigners is higher.

The adjustment of wages to prices is a cardinal point of justice. It should appear in every contract. Unionism makes it possible to adjust wages to meet the cost of living, and the operator should fully avail himself of that and of his happy opportunity to grant essential justice to his workmen without injury to himself. So long as wages were determined by private dicker he could not do this, but now that there is no competition among employers as far as wage is concerned (the matter of bonuses being overlooked) a price is bound to be obtained that will have a definite relation to the wage rate regardless of what that rate may be, high or low.

Difficulties of Mexican Oil Situation

The competition of Mexican and other oil does, however, introduce some uncertainties. Mexico is a country which is not necessarily affected by the same wage changes as the United States. It is an independent variable in many respects. However, the careful reader of *Coal Age* will remember that O. P. Austin showed (Vol. 15, p. 863) that price movements in Mexico are not altogether independent of like movements elsewhere. In fact, sisal grass, which rose in price 300 per cent. in four short years, exhibits the fact that Mexico is getting the full benefit of the world's changed conditions with some of its own added for good measure.

It must be remembered that Mexican oil is a menace in itself, and not merely a menace because it is produced by cheap labor. Moreover, Mexican oil is not the only source of concern. Our own oil, produced, as it is, by well-paid labor, is in the South causing much worry, whereas in the West western coal is triumphing over western oil. Still too much stress must not be placed on oil competition. Wages must be kept where they are, and even raised to meet increased living costs, when they occur, whether Mexican or other oil invades or does not invade the coal market.

A wage which rises and falls with cost of living is not a sop thrown to labor. Today it is one of labor's rights, whereas it was not a right a few years ago, because it could not be safely assured to labor so long as there was a free wage market, where some could concede it and others need not.

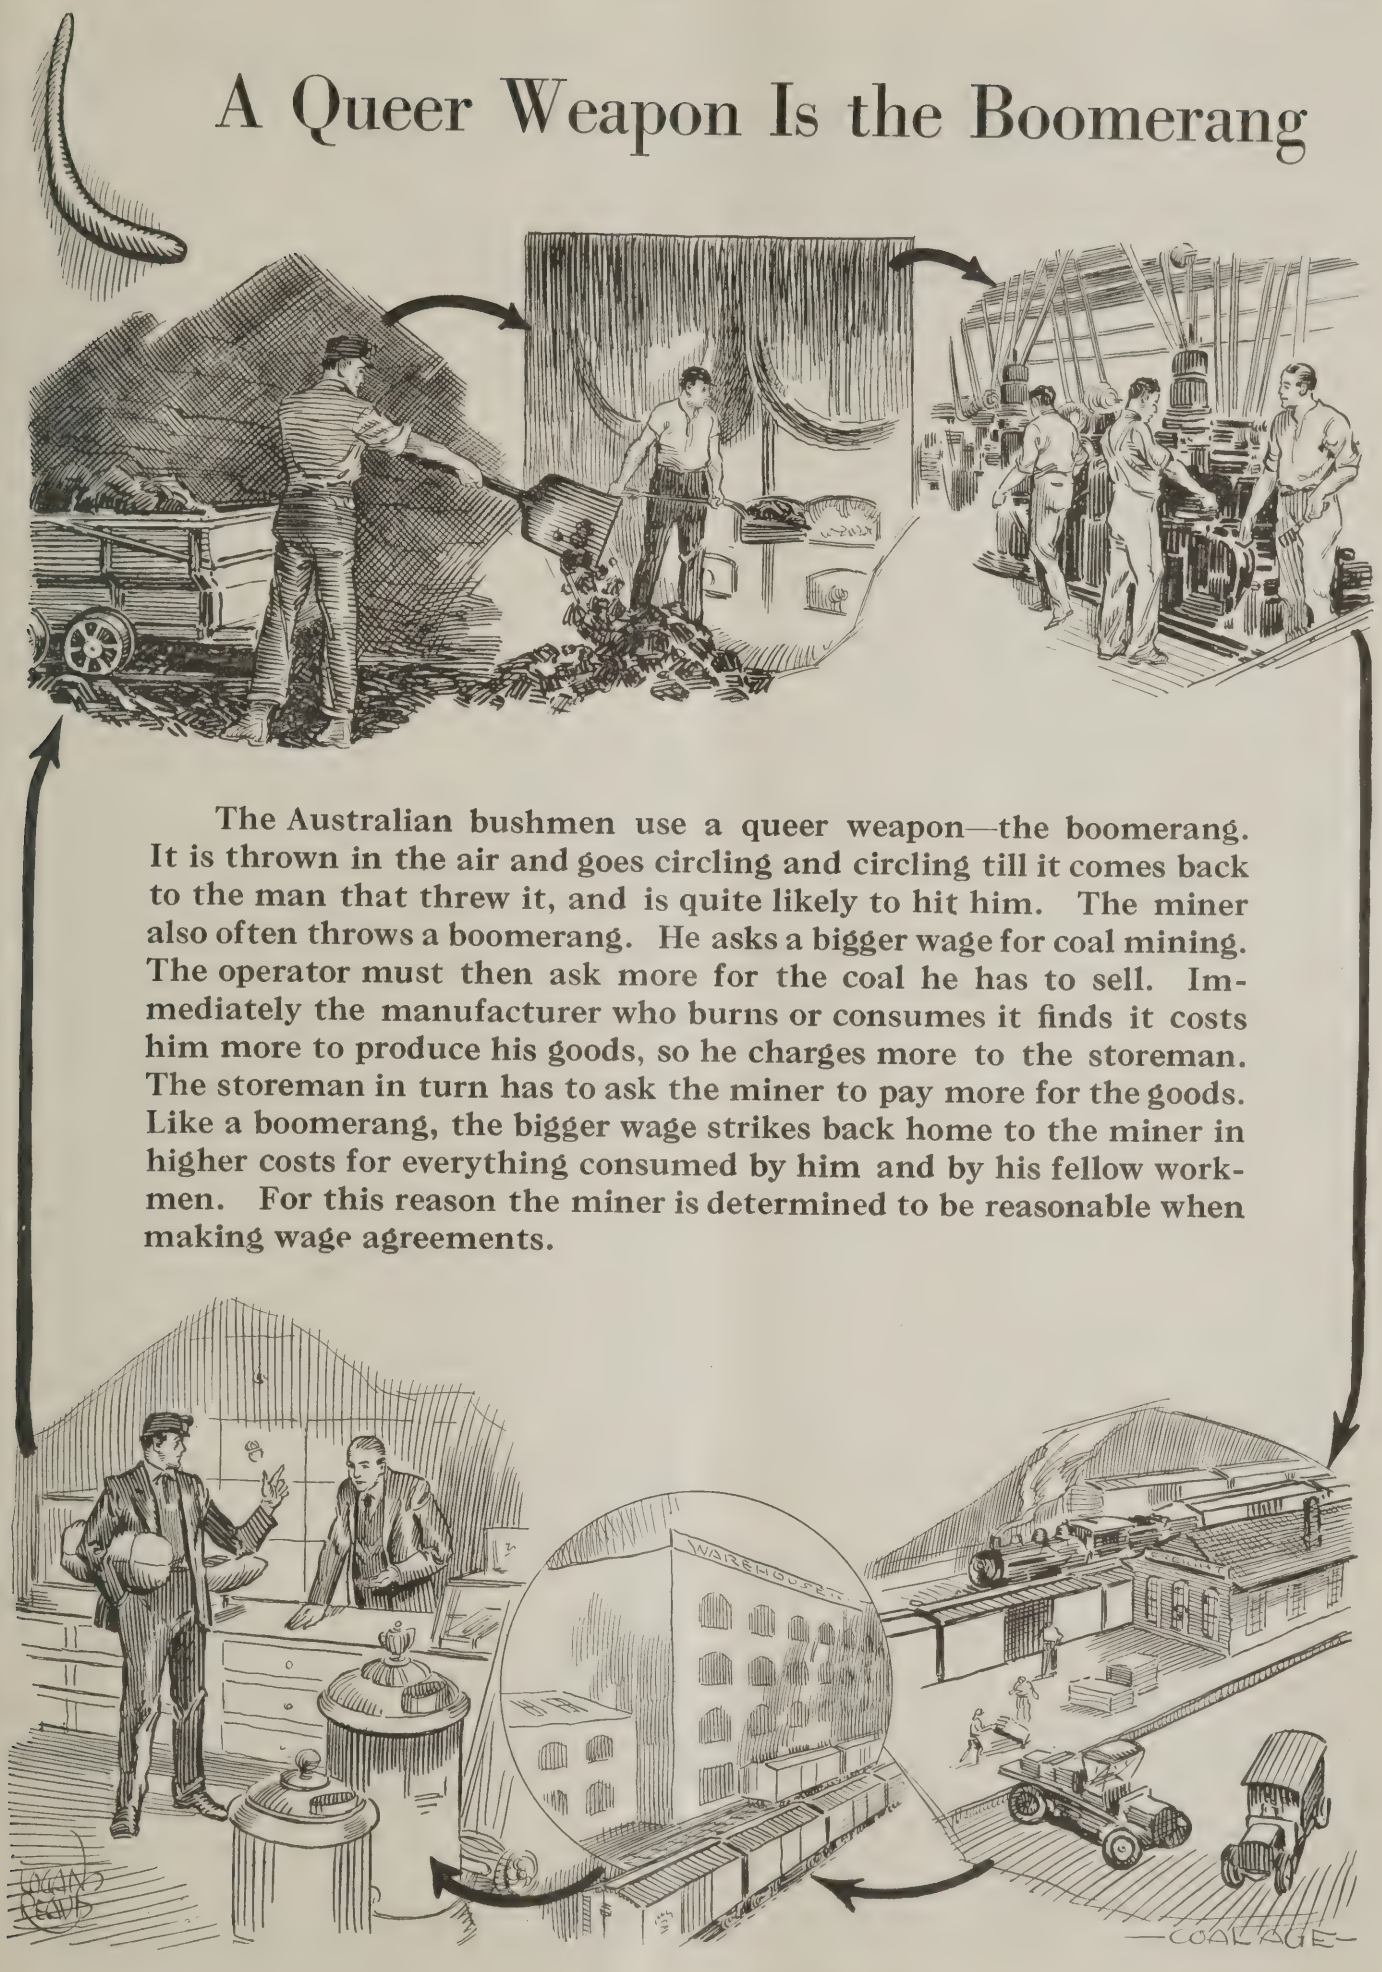
J. D. A. Morrow said at the meeting of the National Coal Association recently that a shortage of 48,000,000 tons of coal was imminent. Dr. Garfield has, it is said, approved that statement. Some say the national labor market is depleted by over 5,000,000 men already, that figure taking in consideration the loss from the cessation of immigration as well as the decrease in the labor force owing to the departure of those who for a time formed a part of our labor forces. According to Mr. Morrow we will lose 40,000 of our foreign coal laborers in the next year. A Wilkes-Barre paper recently stated that from that city and from Hazleton about 1900 workers were preparing to return to their native lands. Shortages like these are quite likely to cause a semi-panic in the coal industry as soon as the public becomes aware of the true situation. Its slowness to buy is making the alien restless and homesick.

The labor situation is everywhere quiet. On the Monongahela River the men, at the Seventh Pool coal mine, organized themselves on May 16 and marched through Greensboro. The mine had been closed down for some time. When it reopened it cut wages 25 per cent. The men demand the scale price.

Strike of Labor Temple Builders in Ohio

By a peculiar irony of fate, mine workers now know how it feels to be the victims of a strike, for the laborers doing the excavating work for the new $100,000 temple of the coal miners at Thirty-fourth and Belmont Streets, Bellaire, Ohio, went out on strike on May 15. As a result, the completion of the new building will probably be delayed for some time.

The men ask for $4.30 per day of eight hours. They have been working nine hours per day and receiving 40c. per hour. Fifteen men laid down their picks and shovels and left their work. Eight teamsters who were working on the job and receiving $1 per hour did not strike.



According to officials of the miners, members of coal miners' unions were to be given preference when men for the work were being secured and after that any man who was a member of a local union could be employed. The R. R. Kitchin Co., of Wheeling, was recently awarded the contract for erecting the temple. The contract calls for completion of the building in ten months from May 1.

Sympathy Strikes Violate Wage Agreement

Officials of the United Mine Workers of America have taken steps to end the strike of coal miners in the McAlester, Okla., district. About 380 miners quit work in sympathy with the striking electrical workers of the Texas Power and Light Co. and the Choctaw Light and Power Co., which furnish electric power for many of the coal mines and also for the homes of the miners. When the union men of the power and light companies walked out the electric companies employed nonunion men wherever possible. The coal miners claimed that the power companies were employing incompetent help and that their lives would be endangered in the mines if they continued to work under such conditions. Several of the largest mines in the McAlester district were forced to close down for a time, including the Rock Island Coal Co.'s mines at Hartshorne and the mine of the Osage Coal and Mining Co. at Krebs.

International officials of the United Mine Workers have telegraphed the leaders of the strike at McAlester, holding that the coal miners are working under the Washington agreement and that they cannot go on a sympathetic strike. All the men were ordered to return to work except in those mines where all equipment is electrically operated. All mines have resumed operation with the exception of Mine No. 10 of the Rock Island Coal Co. at Hartshorne.

A Queer Weapon Is the Boomerang

The Australian bushmen use a queer weapon—the boomerang. It is thrown in the air and goes circling and circling till it comes back to the man that threw it, and is quite likely to hit him. The miner also often throws a boomerang. He asks a bigger wage for coal mining. The operator must then ask more for the coal he has to sell. Immediately the manufacturer who burns or consumes it finds it costs him more to produce his goods, so he charges more to the storeman. The storeman in turn has to ask the miner to pay more for the goods. Like a boomerang, the bigger wage strikes back home to the miner in higher costs for everything consumed by him and by his fellow workmen. For this reason the miner is determined to be reasonable when making wage agreements.

DISCUSSION BY READERS

EDITED BY JAMES T. BEARD

Punishment of Intimidators

Letter No. 1—I read with interest the brief reference to the action of the Raleigh County Grand Jury, in West Virginia, which indicted 19 members of the District Local, for recent acts of intimidation at the mines of the E. E. White Coal Co., *Coal Age*, Apr. 3, p. 630. The announcement led me to reflect and wonder if those who think that the American Government is radically wrong in its methods of conducting its industries are not more pronounced in giving expression to their ideas than those who have greater faith in their government and believe that it is the best on earth.

A man who finds fault with existing conditions is entirely within his rights as long as his fault finding does not find expression in acts of violence and the intimidation of others. But, when it comes to the overturning of existing systems and authority, by a group of individuals, we face a revolution. Revolutions are justified only in rare instances and are, at all times, highly dangerous.

Under our republican form of government, the fellow who repudiates authority and strives to upset law and custom is either misguided or guilty of having wrong intentions. The high officers of the United Mine Workers of American have rightly advised all their locals against any concerted movement for a strike in behalf of "slackers" or "conscientious objectors," who have gotten themselves into jail by reason of setting themselves against the authority of the nation.

Submission to Government Essential

It is poor logic to think that one can support and uphold the Government and, at the same time, seek to enforce a demand for the release of any one man or group of men who have violated its laws and been thrown into jail to await their trial. Obviously, such a demand is a clear repudiation of the regularly constituted authority and must be so regarded. There are men of socialistic inclinations, though otherwise high-minded and regardful of law and order, who are led to support and favor the making of such a demand on their government. Such inclinations are akin to the socialistic tendencies that animate the I. W. W. and stand for revolution.

Certainly, a personal friend of a prisoner who is suffering for his acts of disloyalty or violation of law has a right to petition the Government for leniency or clemency in his friend's behalf. But, when it comes to a group of men making such a petition and accompanying it with a threat or act of intimidation, it is time for good people to get busy.

When established authority is not free to enforce law and order, and if its decrees are repudiated, there is no government worthy of the name. It is a pity that men of good intentions and kindly natures become blinded and fall victims to class prejudice that would lead them to support any movement that would subvert law.

Never was there greater need for law abiding citizens than today, when the future of our country depends on the overwhelming loyalty of the people who enjoy its privileges. The fact that German propaganda is at work to overthrow the peace and prosperity that we enjoy is sufficient argument for the full punishment for intimidators such as those indicted by the Grand Jury of West Virginia.

LOYALTY.

Clinton, Ind.

Waste of Coal

Letter No. 6—I was much interested in reading the letter by a Colorado mine foreman on this subject, *Coal Age*, Mar. 20, p. 544. As he intimates, in his letter, while there is undoubtedly much coal lost after it has reached the surface, a much larger loss occurs in the mine.

Briefly stated, the principal sources of loss of coal are the following: (1) The fine coal and slack produced in blasting and cutting the coal. (2) Coal left in mine pillars instead of being recovered. (3) Loss in loading at the tipple. (4) Loss in storage by reason of sizes being reduced and ground to dust. (5) Loss in transportation to market. (6) Loss by improper methods of firing. (7) Unburnt coal thrown away in the ash.

Now that the war is over we do not hear the cry so often raised during the past two and three years, "Save coal to win the war." It is to be hoped that the lessons learned in the conservation of coal and other supplies will not be forgotten. One of the most important of these lessons is the need of avoiding the waste of coal, particularly, in the operation of the mines.

In the letter to which I have referred, the foreman alludes to the waste in machine mining, because four or five inches of coal were left on the bottom. Where the floor is a soft fireclay, this bottom coal is often of great assistance in shoveling. It gives a smooth hard floor, quite different from the soft clay that makes the work of shoveling coal so often laborious. The trouble is much aggravated if the bottom is wet. However, four or five inches of bottom coal should not be left to be lost, but should be wedged up and loaded out as the place advances.

Where coal is underlaid with a dry clay bottom, the waste of bottom coal can be avoided by putting the mining or undercutting in the clay. In starting such a cut it is necessary to take up a sufficient thickness of the clay to lower the machine; but, after the first cut is made, this work will not be required.

The loss in pillar workings is often very great because of an improper method of drawing the pillars. It frequently happens that the pillars between rooms are too small and so badly crushed by the weight of the overlying strata that they cannot be drawn with safety. When this is the case what is needed is a better plan of driving the rooms. The distance between the rooms will have to be increased or the rooms driven at a less width.

All pillar coal should be removed as quickly as possible after the rooms have reached their limit, so as to avoid the drying out and the crushing of the coal be-

fore "robbing" is commenced. The most important consideration, in room-and-pillar work, is to see that the pillars are strong enough to withstand the weight of the overburden. C. McMANIMAN.

Rawdon, Quebec, Canada.

Barometer vs. Outflow of Gas

Letter No. 2—It is quite true, as E. P. Brennan has pointed out in his letter, *Coal Age*, Apr. 3, p. 634, that the indications of the barometer have an important bearing on the possible dangers that arise from the presence of gas in mines. In this country the variation of barometric pressure may range from 28 to 31 in. of mercury column, which corresponds to a range of atmospheric pressure from 1980 to 2192 lb. per sq.ft.

It has long been observed in coal-mining practice that an increase of gas in the mine air occurs at times when the barometer is falling, and it was common to accept the indications of the barometer as a gage of the relative safety of the mine atmosphere. A falling barometer is still generally accepted as a warning that calls for greater vigilance and the exercise of certain precautions to keep the mine workers safe.

It is quite generally agreed that the same change of pressure that causes the fall of the barometer results in the expansion of the air and gases pent up in the waste and abandoned places in mines. The expansion of this volume of gas-charged air causes an outflow of the same into the mine workings and endangers the lives of the men working in their places. The more sudden the fall in atmospheric pressure, the more observable the results that attend such a condition in the mine.

For example, only a few days ago, Sunday, March 9, the barometer fell 0.85 in. in 16 hours, causing a marked increase in the gaseous condition of many of our large mines having a considerable extent of abandoned areas. It is the sudden changes in barometric pressure that are more dangerous in their effect in the mines.

In England, it was the rule that the fireboss had to read the barometer every morning, before descending the mine shaft, and make that reading a part of his report. As Mr. Brennan has stated, "Mining men have been led to rely on the indications of the barometer," and I hope that this discussion will show how far it is safe to take barometric readings as a guide to safety in coal minig. TIMOTHY GOLDON.

Letter No. 3—Reading the letter of E. P. Brennan, which appeared in *Coal Age*, Apr. 3, p. 634, my attention was particularly arrested by one statement that read as follows: "Personally, I fail to see why a barometer when properly constructed should not adjust itself simultaneously with any change in the atmospheric pressure when that takes place."

In this regard let me state that a barometer certainly does adjust itself to every change in atmospheric pressure. However, there is a great difference between the sensitiveness of the mercury column of the barometer and the sensitiveness of a large volume of air and gases forming the mine atmosphere.

Owing to the greater sensitiveness of the air, the effect of any change in atmospheric pressure is more quickly felt in the mines, where an increase of gas may be observed some little time before there is an observable change in the height of the barometer. At the mines, we commonly speak of that instrument as the "glass."

Some years ago, it was the custom in England to issue daily warnings of the changes taking place in the barometer. These warnings were sent out from a central observatory, to all coal mines, to enable them to use greater precautions and watch all gobs and abandoned places for any undue discharge of gas into the mine workings. But such warnings were eventually discontinued, because it was found that they were quite generally received after the increase of gas in the mine had been observed. Nevertheless, the barometer is still regarded as an important item of equipment at all large coal mines.

Calculating Expansion of Confined Air and Gas

A simple calculation, based on the application of Mariotte's law, which makes the volume of air or gas vary inversely as the pressure, will show the effect of barometric changes. For example, suppose an old waste in a mine contained 50,000 cu.ft. of gas-charged air, and the barometer fell from 30 to 28.5 inches. The expansion of this volume would then be

$$28.5 : 30 :: 50{,}000 : x = 52{,}631 \text{ cu.ft.}$$

The volume of air and gas forced out into the mine workings, by reason of this expansion, is therefore 52,631 — 50,000 = 2631 cu.ft.

Owing to the far greater density of mercury, as compared with the gas-charged air in mines, it is only natural to believe that air and gas respond much more readily to a fall in atmospheric pressure than the mercury column of the barometer. Allow me, here, to illustrate this point by some actual observations showing the effect of changes of barometric pressure on air and gas in mines.

At the mine where I am at present employed, there are two pairs of entries that have been sealed off by means of a 12-in. concrete wall built in each heading. A 4-in. iron pipe equipped with a valve was built into each wall near the top. It is the custom to open these valves every day, to observe the pressure of the atmosphere contained in the enclosed space.

Barometric Effect Clearly Shown in the Mine

Some days when the barometer is low, having fallen during the night, a strong pressure is manifested when the valve is opened. At such times there will be such a strong rush of gas and air from the pipes that it is difficult to hold one's hand against the mouth of the pipe. At other times, when the barometer is high or rising, there will be little or no pressure manifest when the valve is open. There may even be a strong suction, drawing air from outside into the enclosed space behind the wall.

At times, I have observed a neutral condition, when air was neither discharged nor drawn into the pipe and, on my return to the surface, I would find that the glass was just on the point of changing. Indeed, I came more to rely on the manifestations of these valves than I did on the glass. There are many instances on record where gas has been observed flowing from the waste places into the mine workings long before such a condition was indicated by the glass.

On one occasion I recall that one of the valves continued to show a constant pressure behind the wall, irrespective of the changes in atmospheric pressure indicated by the glass. This was in strong contrast to the

manifestation of the valve in the other wall, which conformed with the action of the barometer.

When I mentioned this peculiarity to the officials of the mine, they explained the difference by saying that there had probably occurred a large fall in one of the rooms in that enclosure that had released a feeder of gas that continued to flow into the confined space and created a strong pressure that bore no relation to the pressure of the atmosphere. This explanation seemed reasonable, and, after a time, the excess pressure was relieved by opening the valves and allowing the gas to escape. Later, the manifestations became normal.

West Frankfort, Ill. GEORGE BOWKER.

Certification and Safety

Letter No. 4—I have been deeply interested in the discussion regarding the certification of mine officials and its relation to the safety of the mine. The letter signed "Essex" *Coal Age,* Apr. 24, p. 766, particularly arrested my attention, as the writer attempted to defend the illiterate practical man, and argued that he "should not be denied his place of service in a mine where the company or the operator has confidence in his ability to safely control the operations underground."

Allow me to say that, in my opinion, there can be no such person as an illiterate, practical man. It is impossible for me to conceive how a man who can neither read nor write can become a practical mine official.

Certainly, the practical mine foreman must know enough about arithmetic to enable him to measure air correctly and determine how much air he is getting for each man working on a split. He must be able to estimate what length of sidetrack will hold a given number of cars; or tell how many rails, ties, spikes, splice bars and bolts are required for a certain length of track. He must be able to scale distances from the mine map and determine the direction or bearing of any proposed heading, and do many other like things that require a simple knowledge of arithmetic, embracing addition, subtraction, mulplication, division, and decimals.

A Really Practical Man Will Study

It is my belief that a man who is intelligent and practical enough to be a mine official will be practical enough to learn to read and write and do simple arithmetic, and will have some knowledge of mine gases other than what he has been able to learn of them in the mine. Most of us can remember how the old practical miner used to tell us that he could detect carbon monoxide with his safety lamp; whereas, we all know that if enough of this gas was present in the mine air to detect it by the lamp it would cause instant death.

Practical men have often scoffed at the idea of a dust explosion resulting from a blownout shot; but the study of mine gases and dust explosions has made clear the danger arising from the accumulation of dust in working places where blasting is performed. By the study of gases, we find that firedamp mixtures tend to accumulate at the high points and in the rise workings of a mine, while blackdamp sinks to the lower places and collects in dip workings. This is because the former is lighter and the latter heavier than air, at the same temperature and pressure.

Even with my 28 years of experience in mines I would hesitate to accept the position of mine foreman at a mine, if I could not pass the written examination held in the bituminous districts of Pennsylvania. To accept of such a position without being certified as to my ability to fill it would cause me to feel that I was an impostor. I believe that a certified man realizes the dangers he must meet in the mine, because he has studied carefully the conditions surrounding the work. He is thoroughly acquainted with the requirements of the mining law. An uncertified man may have read over the law, but there is a difference betwen reading and studying the law.

By all means, then, let mine officials be certified as to their ability to fill the positions they hold. The study required to fit them for passing the necessary examination will develop their minds and teach them how to think, which is most essential in mining work where a man is often called to make a quick decision and display good judgment at the same time.

On the other hand, all learning and no experience in practical work is as bad as having years of practical experience with no knowledge of theory. The five years required by law seems a short time for a man to become a practical mine foreman. It is my belief that he should be at the face, mining coal, for at least two years, and the balance of the time be employed at general labor in the mine.

In closing, let me say that workers, as a rule, have no respect for the uncertified man. Neither do they regard the certified man if he has had little or no practical experience in mines. I have formed this opinion from my own observation in such cases, which convinces me that a foreman must be able both to tell a man how to do a certain piece of work and to give him all necessary instructions if he fails to understand.

Midway, Penn. W. J. LYKE.

Letter No. 5—Carelessness and indifference about the mine is claiming an awful toll on the lives of mine workers. If the Coal Mining Institute of America, the members of which are said to have discussed the subject of the certification of mine officials in its relation to safety in mines, could not reach a definite conclusion in respect to this matter, it is to be hoped that such will not be the case with the readers of *Coal Age;* but that the opinions expressed in these letters will be overwhelmingly against the employment of uncertified men as mine foremen in our mines.

In considering this question, I have not been able to understand, nor has anyone explained to my satisfaction, how an intelligent body of men, such as our legislators should be, could annul the requirement of the law making certification of mine foremen necessary. Why did they not go a step farther and throw down the bars completely, by rescinding the law requiring the state examination of mine inspectors. It would then be possible for any old politician to be a successful applicant for that office, and the mines would go to smoke.

It frequently happens that the first question asked on a mine foreman's examination is one that reads somewhat like this: "What is the principal purpose of the law requiring the employment of a practical and competent mine foreman?" This question shows that the body of men constituting the examining boards in Pennsylvania realize the necessity of passing, in the examination, only those who prove their ability and show by their answers that they are both practical and competent in respect to the safe and economical operation of a coal mine in their charge.

Allow me to quote briefly from the bituminous mine law of this state: Art. 4, Sec. 1, reads as follows:

In order to secure efficient management and proper ventilation of the mines, to promote the health and safety of the persons employed therein, and to protect and preserve the property connected therewith, the operator or the superintendent shall employ a competent and practical mine foreman for every mine where ten or more persons are employed.

No one will deny that this was a sane and sensible act, worthy of men of high ideals and aspirations, whose chief thought was to protect the lives and property of those concerned. Now, for another body of men to pass an act allowing any operator or superintendent of a mine to employ an "equally competent man" makes one think that the legislators were unduly influenced by those whose self-interests were the first and strongest consideration and with whom the safety of the mine workers was a matter of minor importance. It is about what we might expect if a farmer was to undertake to operate a mine. When I think of it, I cannot call to mind a single man who is capable of running a mine and not capable of passing an examination for a certificate of competency before a regularly constituted mining board.

A Mine Hopelessly Ruined by an Uncertified But "Equally Competent" Foreman

Sitting here, at my desk, I can see a mine whose history and condition today is one that furnishes an illustration that should convince the most skeptical in regard to the need of the certification of mine officials. The superintendent of this mine is a man who knows nothing of practical mining and who hires the "equally competent" men to run it for him. In the operation of this mine, mining laws and regulations have been ignored, entry stumps have been robbed to such an extent that a squeeze or creep started.

In one instance, six miners, a driver and his mule were all working under a rock that, to look at it, would cause one's hair to stand on end. The rock had been cut off on both sides and the props supporting it were broken with the weight. The mine has now been shut down by order of the state inspector, and the entire equipment has gone to ruin so that it is doubtful if the opening will ever be operated again.

Coal Mining a Hazardous Occupation

The mining of coal is not a farmer's job, but one of the most hazardous of occupations. In coal mining, therefore, the slightest deviation from the most rigid laws and regulations should not be tolerated. This is not the time when we can be slack in respect to our duty of protecting men and property.

Considering the number of men employed in our mines who do not understand the first principles of mining, and the many who cannot speak or understand the English language, it behooves the state to pass laws that will provide for educating mine workers and protecting them by compelling the employment of competent men to take charge of the work.

Every effort must be made to teach mine workers to protect themselves; but this cannot be done when coal operators are willing to employ bookkeepers, barbers, store clerks, and other incompetent men as mine officials. It is time that operators began to play "safety first" in the operation of their mines.

Osceola Mills, Penn. S. D. Hainley.

Prime Producer in a Coal Mine

Letter No. 1—The inquiry that appeared in *Coal Age*, Apr. 3, p. 637, asking who is the "prime producer" in the coal industry, will no doubt bring forth a variety of opinions. For myself, I must beg to differ with the inquirer who is of the opinion that "the actual producer is the loader who takes out from 8 to 12 lb. of coal each shift."

There are many different employees engaged in the work of producing coal and putting it on the market. First, there is the miner who liberates the coal from the strata, loads it into his car and sends it out of the mine. There is no question but that the miner is at the beginning of the production. He is the first man on the long list of drivers, motormen, trackmen, timbermen, cagers, engineers and bosses. However, if I may be permitted to put it that way, I would call the miner the "primary producer."

All the employees engaged in the work contribute their share in the production of the mine; but none of them can justly be called the *prime* or chief producer. All are busy workers, performing their duty in order, and assisting in the movement of the coal from the face to the tipple; but they are all dependent each on the other. To my mind, the man in charge, who commands and directs the work of all is the main spoke in the wheel. In my opinion, he is the chief and the *prime producer*.

It is true, of course, that the wages of all these workmen and the profits of the company besides, come from the point of the pick. But, it must be remembered that, in order to insure the greatest degree of perfection in the entire work, there is required one great head.

As I look at this question, the words "prime producer" mean far more than the first man on the list, or the miner who wields the pick. The words appear to me to embrace the higher meaning of getting the greatest yield, from a given area, in a given time and with the least expenditure of money and labor. On this basis the man in charge of the operation is the prime producer. J. T. Jones.

Rossiter, Penn.

Surveying Without an Instrument

Letter No. 1—I am tempted to offer a few comments on the article of T. Edwin Smith, *Coal Age*, Mar. 27, p. 562, suggesting the idea of making a mine survey when no instrument is available for that purpose and the only means at hand is a steel tape. In his description, Mr. Smith speaks of "lining in" two points on a section line, after locating one stake a quarter of mile and another a mile and a quarter away, on said line.

It would be interesting to know how any one would place any reliance on the subsequent work of a survey started in this manner. How is it possible to line in the two points that he mentions, at distances 20 ft. apart on the section line, or to project that line, without the use of an instrument.

The method described for finding the angle that a line, drawn from one of these points to another point located at the mouth of the mine, makes with the section line, is simple and would suffice for turning an angle or two in case of necessity. But, to apply this method for connecting a mine survey with the section line on the surface is certainly open to criticism.

If the three points used to represent the apices of the triangle happen to be ½ or even ¼ inch off their respective lines, there would result a grievous error in the survey projected from this triangle as a starting point, or employed to determine the course or bearing of the first line of the survey. Should one or both of these points be slightly off the true line, the error in the location of the stake at the mine entrance would probably be greater than the permissible error of any ordinary transit survey extending through a 2-mile circuit.

At the close of his article, Mr. Smith suggests that a steel tape stretched close to the ground is but slightly affected by a high wind that would render the observations taken with a transit unreliable. It is my experience that chaining or measuring in a high wind is a greater source of error than sighting through a transit, under the same conditions. I believe that practically all of the errors in surveys made in high winds can be attributed to chaining, and very little to the effect of the wind on the instrument.

There is no doubt, as Mr. Smith remarks, that "the accuracy of the results will depend upon the care taken in sighting the lines and measuring distances." This is true of all survey work, and it does not appear that the care to be taken is an argument in favor of the proposed method, more than when using an instrument in making a survey. Indeed, I will say that the most extreme care is needed, in the alignment of points without the use of an instrument for that purpose. An error of ¼ inch in a distance of 20 ft. makes an angular error of 4 minutes, which exceeds the allowable error.

Piney Fork, Ohio. F. C. SANNER.

Efficiency in Mine Management

Letter No. 5—The letters that have been written dealing with the question of efficiency in the management of mines have apparently neglected to mention one or two vital points in practical management. In order to secure the highest efficiency in any operation, it must be studied in detail.

In coal mining, one must start his investigation from the time the coal is taken from the working face until it is dumped over the screens on the tipple, ready to be shipped to market. By a careful survey of the situation, it will be found that, while negligence begins at the working face, the real fault can generally be traced to the failure of the management to choose men who are capable and trustworthy.

Employ Competent Men with Full Authority to Act

Success depends on employing only such competent men and giving them the authority they need to enforce discipline in the mine, and then holding them responsible for getting results. If it can be shown that men in charge of work are not fitted for such responsibilities as should be theirs, I would ask, "Why should they be retained on the payroll?"

Allow me to refer briefly to at least two items that are by no means uncommon in the management of coal mines, and yet interfere seriously with the highest efficiency attainable in the work. One of these items is the frequent derailment of cars in mines. This is most observable, in my experience, in machine mining where short rails or "jumpers" are used so as to enable the cutting machine to pass freely across the face, without interfering with the roadway. Several years of experience, in the movement of coal from the face to the tipple, enables me to give a close estimate of the number of derailments that are liable to happen.

Say, for instance, from 8 to 10 cars are taken from a single working place, daily. My observation is that an average of one of these cars a day will be derailed as the result of improper discipline on the part of the men in charge and for whom the management are responsible. Consider, for a moment, what this condition means, in a mine employing 400 loaders. All must agree that it will mean a marked decrease in the daily tonnage, to say nothing of the dissatisfaction of drivers, motormen and loaders, all of whom are delayed by reason of such derailments.

I recall to mind a particular instance where a motor, hauling a train of from 6 to 8 cars at a time, was compelled to pass over a switch not more than 7 ft. in length. To my remark that the switch should be twice that length, the partingboss replied that "a man in the office figures all those things by direction of the manager." But practical mining men know that such a length of switch can only be used in mule haulage, and will result in no end of delay in motor haulage.

Unpractical Work Charged to Office Men

In the instance just mentioned, the same figures were applied to all switches in the mine, whether in rooms or on the main parting. Such a condition does not speak well for either the technical or practical knowledge of "the man in the office," or yet for the efficiency of the management that employs him. Attention being drawn to such a matter in a mine invariably brings the reply, "Yes, I know it; but the manager won't stand for anything else, and I must do what he says."

While I do not wish to be understood as suggesting that an under official should go contrary to the orders of the management, I will say that too many under officials accept orders that they know are not practical, without making any attempt to explain the conditions that call for something different.

The cost-sheet is the one thing that is ever before the eyes of the manager, and it is not to be supposed that he is always acquainted with the conditions existing underground. On this account it is all the more important that an efficient management should employ competent men to place in charge of that work, and hold them responsible for the results, allowing them to have complete charge of all construction and repair work.

Unless this is done, the man in charge seldom feels free to do anything but what he knows will meet the approval of the management, and the entire responsibility for the result then lies at the door of said management, because full authority to act in accordance with one's practical experience has not been given, and the man is simply endeavoring, in a blind way, to carry out what he supposes to be the ideas of the management, imperfect and unpractical as they may seem to him to be.

In closing, let me say that it is difficult to understand how companies will employ men to take charge of their work, whom they assume to be incapable of independent judgment and action. Their chief aim and object should be to employ only men having a practical knowledge of coal, haulage, tracklaying, timbering and the handling of men, if they are to get results.

Edwardsville, Ill. CLAUDE W. CARRUTH.

INQUIRIES OF GENERAL INTEREST

ANSWERED BY JAMES T. BEARD

Lamp Extinguished by Gas at Roof

I want to ask for an answer, through the columns of *Coal Age*, to the following question, which has caused some considerable discussion hereabouts:

When making the morning examination in a mine, the fireboss came in contact with a fall of roof on a main heading. The fall left a large pothole extending 8 ft. up in the roof and 6 ft. wide. On raising his lamp up into the hole, the fireboss first observed that the flame became dim and on raising it higher, the lamp was instantly extinguished.

Assuming that the air in this hole was stationary, although the normal current was traveling in the heading, I want to ask what was the cause of the dimming of the lamp flame and its later extinction when raised higher in the hole? An answer to this question in *Coal Age* will greatly interest others beside myself who are constant readers of the paper. STUDENT.

Pryor, Colo.

This question illustrates a situation that has often been explained in *Coal Age*. It is reasonable to assume that some gas is being driven off in the roof strata broken by the fall. The air current not being directed into this cavity, the gas accumulated and more or less filled the hole. Diffusion taking place in the lower portion of the hole, the gas passes off in a thin stratum at the roof, practically as fast as it issues from the strata.

The dimming of the lamp when raised into the hole would indicate that some carbon dioxide is mixed with the methane coming from the strata. This is not an uncommon occurrence in coal formations. At times, the carbon dioxide exists in the strata, but more frequently it has found its way there from adjoining workings or from an overlying, abandoned and worked-out seam.

It is possible for the carbon dioxide, accumulated in old workings that have been sealed off, to find its way through crevices in the roof strata where it becomes mixed with methane and issues into the live workings as a mixture of these two gases. Such a mixture, formed in the absence of air, is lighter than the air (sp.gr. 0.924) and will tend to accumulate in the upper portion of the hole where it issued from the strata. Its diffusion into the air current will be comparatively slow, because of its density so nearly approaching that of air.

When a lamp is raised into such a mixture of methane and carbon dioxide the first effect is a slight dimming of the flame, which takes place as the fresh air in the lamp is being displaced by the mixed gases. A close observation of the flame when the lamp is first raised into the mixture will reveal a small flame cap, which quickly disappears, however, as the flame dims. A little later the lamp is extinguished by reason of the combustion chamber of the lamp being completely filled with the extinctive mixture.

Owing to the brief appearance of a flame cap when the lamp is first raised into the gas, this mixture of carbon dioxide and methane has been called "flash-damp." Although the mixture has not sufficient air to enable it to support combustion, it becomes inflammable and explosive and may be highly dangerous when mixed with air in sufficient proportion. (*Mine Gases and Explosions—Beard, pp. 128, 129*).

Helium

Kindly describe the occurrence, properties and uses of helium, and state what is its chief source of production? STUDENT.

Washington, D. C.

Helium is a light gas, being only twice as heavy as hydrogen; chemical symbol, *He;* specific gravity, 0.139; occurrence very rare. It was first discovered in the spectrum of the sun, whence its name from the Greek *helios*, sun. It exists in extremely minute quantity in the atmosphere and in a few rare minerals, such as uranium, titanium, columbium, etc.

Its chief importance was discovered in the late war when a light non-inflammable gas was sought to replace hydrogen in observation balloons and dirigibles. The gas fields of southern Kansas, Oklahoma and Texas furnish the only supplies of helium for commercial use. The gas coming from these fields was formerly known as "wind gas," because it could not be ignited, and was wasted until the search for helium showed it to contain from 0.5 to 2 per cent. of that element.

Power Transmission

It is proposed to operate a pump located at a distance of 1300 yd. from the power station, and it is estimated that it will require 23 hp. to drive this pump. Kindly state what size of cable will have to be used to transmit the necessary power in this case. SUPER.

Collinsville, Ill.

Assuming 90 per cent. of efficiency in the motor driving the pump, the power delivered at the motor must be (23 x 746) $\div$ 0.90 = 19,065 watts. Then, supposing the pressure at the terminals of the motor to be 250 volts, the current necessary to be transmitted is 19,065 $\div$ 250 = 76 amps.

Finally, allowing for a 15 per cent. line drop, the size of wire required to transmit this current from the power station to the motor, assuming a wire return, will be that having a sectional area, in circular mils. calculated thus:

$$A = \frac{21.6 \times 3(1300)76}{250 \times 0.15} = 170{,}7000 \ circ.mils$$

Reference to a wire table for the transmission of electric current shows that a 000-wire will be required for this transmission, under the assumed conditions.

EXAMINATION QUESTIONS

ANSWERED BY JAMES T. BEARD

Miscellaneous Questions

(Answered by Request)

Ques.—In a certain shaft, the weight of the empty cage is $2\frac{1}{2}$ tons, the empty car $\frac{3}{4}$ ton, loaded car $2\frac{1}{2}$ tons, and the rope hanging in the shaft 2 tons; what should be the small diameter of conical drum when the large diameter is 28 ft., in order to equalize the load on the hoisting engine?

Ans.—To equalize the load on the engine, the net load moment at the beginning of the hoist must equal that at the finish. The load moment is the product of the load on the rope at the drum and the drum radius. The net moment is the difference betwen the load moments of the empty and loaded cages.

At the beginning of a hoist, the loaded cage is at the shaft bottom and the empty cage at the top. The total load hoisted is the sum of the weights of the cage, loaded car and the rope, or $2\frac{1}{2} + 2\frac{1}{2} + 2 = 7$ tons, which acts on the small radius, or diameter (x) of the drum; and its moment is $7\ x$ ton-ft. But the descending load, starting at the top of the shaft, is the sum of the weights of the cage and the empty car, or $2\frac{1}{2} + \frac{3}{4} = 3\frac{1}{4}$ tons, acting on the large radius or diameter of the drum; and its moment is $3\frac{1}{4} \times 28 = 91$ ton-ft.

The net load moment, at the beginning of a hoist is, therefore, $7\ x - 91$ ton-ft.

At the end of the hoist, however, the loaded cage is at the top of the shaft, and the empty cage at the bottom. The total load acting on the large radius is now the sum of the weights of the cage and loaded car, or $2\frac{1}{2} + 2\frac{1}{2} = 5$ tons, and its moment, using the diameter instead of the radius, $5 \times 28 = 140$ ton-ft. The empty cage being now at the shaft bottom, the total load acting on the small radius is the sum of the weights of the cage, empty car and the rope, or $2\frac{1}{2} + \frac{3}{4} + 2 = 5\frac{1}{4}$ tons, and its moment referred to the diameter as before, is $5\frac{1}{4}\ x$ ton-ft.

Hence, the net load moment at the end of a hoist is $140 - 5\frac{1}{4}\ x$ ton-ft.

Finally, equating the net load moments at the beginning and the end of a hoist, and solving the equation for x, gives for the small diameter of the drum, in this case, in order to practically equalize the load on the engine throughout the hoist,

$$7\ x - 91 = 140 - 5\tfrac{1}{4}\ x$$
$$12\tfrac{1}{4}\ x = 231$$
$$x = 18.85 \text{ ft.}$$

Ques.—Why, in mines worked exclusively with locked safety lamps, are explosions less frequent than in mines worked by open lights? State fully.

Ans.—It may be assumed that where the conditions in a mine are such as to require the exclusive use of safety lamps, greater precautions are taken to avoid the dangers due to the presence of gas, than in a mine where open lights are permitted. The greatest danger exists in mines where mixed lights are used. A mine worked exclusively with open lights must be assumed as being one in which gas has never been discovered. The men working in such a mine are mostly those who have no knowledge of gas and exercise no care to avoid possible dangers from that source. The mine may still be generating a little gas, which has escaped detection by reason of the place being well ventilated. A time of idleness or slack ventilation would then bring danger, unless the workings were thoroughly inspected before the men were allowed to proceed to work.

Ques.—When is a mine efficiently ventilated?

Ans.—The ventilation of a mine is efficient when it complies with every requirement of the mining law and the air is distributed about the mine in such a manner as to prevent any dangerous accumulation of gas in the working places and elsewhere in the mine, and the mine atmosphere is thus made safe and healthful.

Ques.—In selecting an explosive for blasting purposes in a mine what are the chief considerations?

Ans.—The chief considerations relating to the choice of an explosive for blasting coal and rock in mines, are the volume, duration and temperature of the flame produced in its explosion; susceptibility to moisture and freezing; and its strength and adaptation to the material to be blasted.

Ques.—If the mine resistance produces a $2\frac{1}{4}$-in. water gage, when the depression at the port of entry of the fan is 2 lb. per sq.ft., the area of the port of entry being 90 sq.ft., and the area of the port of discharge 65 sq.ft.; what is the manometric efficiency of the fan?

Ans.—The solution of this problem depends on the principle that, for the same quantity of air passing, the pressure varies inversely as the square of the area of passage. The first step is to find the total pressure absorbed in the fan. The intake area or port of entry of the fan being 90 sq.ft. and that of the discharge 65 sq.ft., the area ratio intake to discharge is 90: 65. Then, the intake pressure being 2 lb. per sq.ft. and calling the discharge pressure x, the pressure ratio, intake to discharge, is $2 : x$. But, by the principle just stated, the pressure ratio is equal to the square of the inverse area ratio, and we can write:

$$\frac{x}{2} = \left(\frac{90}{65}\right)^2 = 1.92$$
$$x = 2 \times 1.92 = 3.84 \text{ lb. per sq.ft.}$$

The total pressure required to pass the air through the fan is, therefore, $2 + 3.84 = 5.84$ lb. per sq.ft. But, the total pressure absorbed in the mine, as indicated by the water gage of $2\frac{1}{4}$ in., is $2\frac{1}{4} \times 5.2 = 11.7$ lb. per sq.ft. In this case, the total pressure producing the circulation in the mine and the fan is $11.7 + 5.83 = 17.53$ lb. per sq.ft.

Finally, since the manometric efficiency of a fan is the ratio of the pressure absorbed in the fan to the total pressure producing the circulation through the mine and the fan, expressed as percentage, it is, in this case, $(5.83 \times 100) \div 17.53 = 33\frac{1}{3}$ per cent.

FOREIGN MARKETS AND EXPORT NEWS

EDITED BY ALEX MOSS

Exemption of Transportation Tax on Export Coal

Many complications have developed to delay the Bureau of Internal Revenue in making an announcement in the matter of allowing exemptions from the payment of the transportation tax on export coal. The following regulations, however, have been submitted to the bureau by the American Wholesale Coal Association with the hope that they may be acceptable:

Any shipper intending to ship any commodity to any foreign country shall file with the carrier a sworn certificate containing the following information: (1) Character and amount of commodity to be exported; (2) name of the port through which the export shipment is expected to be made; (3) name of the country to which the shipment is to be made; (4) approximate dates between which the export shipments are to be made.

Upon receipt of such information, the carrier shall exempt such shipper from the payment of any transportation tax which is provided by law and intended to apply on domestic shipments. Provided that such exemption shall be considered temporary until the shipper has supplied to the nearest agent of the carrier the following data in proof of the fact that the commodity has actually been shipped into export:

a. A full copy of the foreign bill of lading containing: (1) The character and amount of the commodity exported; (2) the name or number of the conveyance used in exporting the commodity; (3) the city and country to which the shipment is destined.

b. Or a certificate containing: (1) Reference by number to the waybill or foreign bill of lading; (2) character and amount of commodity; (3) city and country to which shipment is destined.

When proof of export is thus presented, the exemption from the payment of the domestic tax on transportation shall become permanent. When there is any discrepancy between the amount originally declared to be destined for export and the amount actually exported, the exemption from the payment of the transportation tax shall be for the amount actually exported.

When the shipment is made through a pool, it will be sufficient for the purpose of proving exemption to show the amount actually exported is equal in quality and quantity to the sworn stipulations in the original declaration of intention to ship into export.

Disposition of Saar Coal Region

According to a recent issue of the *Iron and Coal Trades Review* (London) the following are the particulars regarding the settlement of the ownership of mines, etc., in the Saar Basin, which is the decision of the Council of Four:

The ownership of the mines is transferred to France in perpetuity, and the mines are to come under the provisions of the French laws. Germany, however, is to continue to be responsible for all liabilities incurred by her to the inhabitants of the country in so far as the rights of these people are not recognized by the French laws. France will exercise police functions in the district. The political sovereignty, however, will be assumed by the League of Nations, who will give a mandate to a kind of directory, consisting of five members, one of them an inhabitant of the Saar district, one a Frenchman, and the other three members are to be appointed by the League. The inhabitants of the Saar district will retain all their political rights concerning elections to local representative bodies, but will cease to send representatives to the German Parliament.

This régime will last 15 years, at the lapse of which period a plébiscite is to decide the future political status of the inhabitants of the region. In the case that they should express a wish to remain under the administration of their country of origin, Germany will have to buy up the mines for France, who will be granted their full ownership in recompensation for the damage done by the enemy in the Département du Nord. The estimated purchase price will have to be paid in gold or equivalent securities.

Foreign Coal Trade Opportunity

A firm in Belgium desires to get in touch with American producers of bituminous coal. Correspondence should be in French. References. Those interested may procure further details by addressing the Bureau of Foreign and Domestic Commerce, Washington, D. C., or any or its branch offices, and referring to File No. 29366.

English Coal Market

The London coal market is gradually resuming normal conditions, says *The Colliery Guardian* of May 2. Seaborne arrivals have been fairly maintained and inland truck trade is improving. However, weather conditions and the wholesale arrears of orders on hand keep all business of a hand-to-mouth description. Domestic coals are in strong demand, and all manufacturing coals are keenly wanted.

There are larger supplies of coal for shipment from the Tyne for neutrals this month. Deliveries from Yorkshire are coming through more freely. The mines have now got into full swing, but it will probably take some weeks to overtake the arrears arising from previous low production. Supplies have improved in Lancashire, although restricted by the holidays, but there is a scarcity of domestic coal.

Outputs of coal at Cardiff are not yet up to the normal standard, and there has been a falling off in shipments. Operations are limited by the working conditions, but it is not improbable there will soon be great improvements in the supplies to meet the heavy demands.

Coal Shipments to Switzerland

On May 19 the War Trade Board announced that henceforth shipments of coal to Switzerland may be consigned to the Societe Coöperative Suisse d'Importation du Charbon, and furthermore that it is no longer necessary for importers in Switzerland to obtain certificates from the Societe Suisse de Surveillance Economique covering such importations. Applications on form X-A should be filed with the War Trade Board, Washington, D. C.

Brazilian Coal Imports During February

Vice Consul A. I. Hasskarl, of Rio de Janeiro, reports that arrivals of coal from all sources at this Brazilian port during February amounted to 43,179 metric tons (1 metric ton equals 2,204.6 lb.), of which 38,099 tons were American, and 5080 tons British, coal. The United States furnished 2138 tons in February, 1918, and 47,039 tons in the corresponding month in 1917.

Foreign Freight Rates

W. W. Battie & Co.'s coal trade freight report of May 19 states the following:

Since our last report, three large steamers were chartered to carry coal to ports in Brazil, and we have additional steamers open for such business; also have sailing vessels inquiring for coal to Brazil and the Plate at the chartering executive's rates.

There is very little demand for steamers to carry coal to West Indian ports, and shippers have been trying to arrange with the chartering executive to reduce freight rates (but without success), as such a reduction would help this business materially.

We have a number of steamers inquiring for coals to European ports, and think in the near future we will be able to secure tonnage for Genoa at $26.50, 1000 tons discharge, and Gothenburg, same terms—this gross form charter, freight in advance, no deduction.

The chartering executive's rates are as follows:

Steam—Havana, $7.50, 600 tons dis.; Cardenas or Sagua, $9, 300 tons dis.; Cienfuegos, $9, 500 tons dis.; Caibarien, $9.50, 300 tons dis.; Guantanamo, $8.50, 500 tons dis.; $9, 400 tons dis.; Manzanillo, $9.50, 300 tons dis.; Bermuda, $9.50, and Bermuda, p. c. and dis. free, 300 tons dis.; Kingston, $9.50, 400 tons dis.; St. Thomas, $10, 500 tons dis.; St. Lucia, $11, 500 tons dis.; Santiago, $8.50, 500 tons dis.; $9, 400 tons dis.; Barbados, $11, 500 tons dis.; Port of Spain, Trinidad, $11, 500 tons dis.; Curacao, $10.50, free p. c. Curacao, 500 tons discharge. Rio, $19.50 net, 1000 tons dis.; Santos, $19.50 net, 1000 tons dis.; or $21 net, 600 tons dis.; Rio Grande do Sul, $22, 500 tons dis.; Buenos Aires or La Plata, $18.50 net, 1000 tons dis.; Montevideo, $19.50 net, 750 tons dis.; Pernambuco, $18.-50 net, 500 tons dis. Bahia, $18.50 net; Bahia Blanca, $20, 1000 tons dis. To Nitrate Range, $16.50 gross prepaid.

Sail (maximum) — Para, $15.50 net; Bahia, $18.50 net; Pernambuco, $18.50 net; Rio, $19.50 net; Santos, $19.50 net; Rio Grande do Sul, $20.50 net, 400 tons dis.; Buenos Aires, $18.50 net; La Plata, $18.50 net; Montevideo, $19.50 net. To Nitrate Range, $16.50 gross, prepaid.

COAL AND COKE NEWS

Harrisburg, Penn.

Senators and representatives from all sections of the state are being stormed with letters and telegrams protesting against the Mangan bill which reduces the standard weight of anthracite coal from 2240 to 2000 lb. The bill, which slipped through the House with scarcely any attention, is backed by the anthracite coal operators and retail coal merchants, and was introduced by Mr. Mangan, according to his statement, at the request of the wholesale and retail coal dealers of Allegheny County. Most of the letters received were from the eastern section of the state, and the protestants pointed out that the bill was sponsored by western interests where comparatively little anthracite is used.

Representative Mangan states the bill is justified by western Pennsylvania conditions, and he produced letters from coal dealers to prove his point. He also said that it was impossible to punish coal dealers who collected the price of a long ton for a short ton of coal, because the present law specifying that anthracite coal shall weigh 2240 lb. to a ton carries no penalty for violations.

Under existing legislation 2000 lb. to a ton is the standard weight of bituminous coal. Coal dealers complain that when they price anthracite at say $7.45 a ton of 2240 lb., some dealers quote the net ton of 2000 lb. at $6.65. This price, dealers complain, appears less, but actually is the same price per hundred weight. The general public, the dealers say, do not understand this and therefore place orders with the dealers who appear to be selling at reduced prices.

The Mangan bill imposes a penalty of $50 for each violation of the provision that coal shall be sold at a standard weight of 2000 lb. The bill is now in the Senate, where it is understood, an effort will be made to amend it, bringing the standard weight up to 2240 lb. While the bill will make little difference to miners who are paid by the car, it will benefit those who are compensated by weight.

Compensation amendments proposed by the state administration bill were given a hearing before the Senate judiciary general committee on May 20. After all the arguments were heard, the attorney general said there were only slight differences. General Schaeffer summed it up by saying that in the main features it was similar to a question of 50 per cent. of $24 dollars or 60 per cent. of $20. Henry W. Moore, of Philadelphia, speaking for the Manufacturers' Association discussed the medical charges and waiting period; Henry I. Wilson, speaking for the Central Pennsylvania Coal Operators' Association, objected to the payment to widows after remarriage as "establishing a peculiar precedent"; also noting the provision for supervision of payments to dependents, by the State Board. He suggested that guardians should be named. Evan C. Jones, of Wilkes-Barre, representing the anthracite interests made objection to the plan for determination of wages on a basis of gross earnings without deducting supplies and labor in anthracite mining as "an untrue" basis, and to the method of determination as involving too much search.

F. M. Painter, speaking for the Pittsburgh Coal Operators' Association, suggested changes in procedure, one being that agreements be altered as of the time when status changed; no awards be made on incompetent testimony; notice of appeals to court be given by appellant and that courts be empowered to dispose of cases instead of returning them to the State Board for review.

The interests were represented by James H. Maurer, president of the State Federation of Labor, Thomas Kennedy, head of the mine workers of the Lehigh field and Roger Devers, counsel for the mine workers. They asked that if the present amendments were not acccpeted, to let the present law stand as it is.

It developed at the meeting that if the employees were given an advance in compensation at the present session, that, if conditions warranted, they would ask for an increase at the next session also.

Charleston, W. Va.

A livelier demand in all markets was reflected in greater activities among the mines of West Virginia during the week ended May 17, that period even showing improvement over the first ten days of this month. At the present rate of production, May will prove to be the best month of the year, as in several fields the amount of coal mined is rapidly rising to normal, in no field being under 50 per cent. It is predicted that within a month conditions will be even more satisfactory. All classes of consumers now appear to be using more coal not so much as a temporary measuse, but because of regular needs. In certain fields the export demand is strong as a result of increased ocean shipping facilities; at the same time the demand for coal is growing in Lake areas. The effect of the increased demand has been of course to at least hold prices to government fixed rates if not to increase them somewhat.

While business has been much stimulated among the companies operating in the Kanawha field, the output of that particular district was on May 17 still a good many thousand tons below full time capacity. Insofar as it was possible to tell, however, mines were working about half time, or in other words, had produced during the week in question approximately 100,000 or perhaps 110,000 tons; any increases came largely from lake sources, although the general western market seemed to be much more active as indicated by inquiries for Kanawha coal. Taking them by and large, operators of the Kanawha region have been in no rush to ship coal until it could command a price insuring reasonable profit.

As was the case during the weekly period ended May 10, so it was also true of the week following; mines in the New River region were practically all working full time not only in getting out domestic coal but coal for export as well, the export trade having shown a spurt, probably because of the fact that more vessel space was obtainable. However, shipments to tidewater are being governed somewhat by the arrival and sailing of vessels. Insofar as it is possible to gage it, 200,000 tons or more a week were being produced during the week ending May 17. The labor shortage in the New River and Kanawha fields was not quite so pronounced as during the earlier part of May, the fact that mines were working regularly having caused the return of many miners to the field. A large part of New River smokeless is being shipped to Lake ports. Slack coal is moving out rather slowly and therefore is lagging a little in price, but is expected to reach old levels in the near future.

Fairmont, W. Va.

By May 17 production had reached the highest level of the present year in the Fairmont and other northern West Virginia coal fields, activities in the field being much more in evidence than was the case even at the beginning of May; it was estimated that in the three weeks which have elapsed since May 1 the output is fully one-third greater in volume than was the case at the first of the month, the loadings as an example, on the Monongah division alone being over 800 cars a day. Consequently there is less idleness among the various mines in the northern part of the state and it is believed that production is in the neighborhood of 80 per cent. Impetus in part has been given to shipments from northern West Virginia points through a growing demand for coal to be exported, daily shipments averaging as high as 167 loads from one railroad division. By May 17 there was also a considerable tonnage of coal being moved eastward for use on the railroads as well as for general industrial purposes. Western shipments also were materially increased during the week ended May 17, a large tonnage of coal being for Lake delivery. Such coal as is mined for export is being sent to Norway, Sweden and Italy. Prices for run-of-mine coal on spot sales have been running from $2.15 to $2.65 a ton. Some contracts have been made with the Baltimore & Ohio as low as $1.75 a ton, however.

Arrangements are being rapidly completed for the establishment of a rescue station at Fairmont, W. J. Heatherman (chief of West Virginia Department of Mines) and his chief clerk having been in the Fairmont territory where an examination for mine foremen was held during the week ended May 17. The equipment at the Fairmont station will be equal to that found on the average government rescue car and will consist of five helmets, a pulmotor and other equipment needed at a rescue station. Both Mr. Heatherman and Mr. Heiser went to Pittsburgh recently to make arrangements for the purchase of equipment.

Dallas, Tex.

Extensive development of the coal beds in Webb, Uvalde and other Texas counties along the Mexican border is probable, as much attention has been directed to that section of Texas by the recent bulletin issued by the United States Geological Survey. Coal has been known to exist in Webb and Uvalde counties for many years, and has been mined to a considerable extent at Santo Tomas Darwin and Dolores. Most of the railroads in southwestern Texas and in Mexico adjacent to the border have been supplied from these mines. The mining has been confined largely to the outcrop of the seams, however, and little effort has been made to mine the coal any great distance from the outcrop.

The coal occurs in two principal beds, both of which can be traced for a considerable distance along the banks of the Rio Grande, in Webb County, to a point where the coal outcrops swing northward into Uvalde County; here the seams dip somewhat. Two principal beds can be traced, about 90 ft. apart. The beds range in thickness from 2 to 2½ ft. and appear quite persistent.

This coal, geologically, is of considerable interest as it occurs in rocks that elsewhere in Texas bear only lignite, yet the coal here is bituminous. It has the qualities of cannel coal, contains a large amount of volatile matter, and it yields oil by distillation—about 50 gal. to the ton.

Mining has been hampered in this section by the nature of the rock forming the roof; it is of a loose sandy nature and requires timbering. As there is no timber in this section it has proved a drawback to mining operations. The additional cost of shipping in timber has been such that heretofore mining has not been attempted on a large scale where timber had to be used. Several large companies are being organized or considered, and extensive development in this field in the near future seems likely.

Victoria, B. C.

Two important actions, both involving title to the disputed coal rights of the Esquimalt & Nanaimo Railway belt, Vancouver Island, British Columbia, will come before the Privy Council in England this Summer. Hon. J. W. deB. Farris, Attorney General of the province, leaves shortly to appear before that court on behalf of the province. One of these cases is that between the E. & N. Ry. Co. and H. W. Treat, the latter being a resident of Seattle, Wash. A lease to certain foreshore on the east coast of Vancouver Island was given to Mr. Treat by the provincial Government and to this property the company claims ownership, by virtue of the terms of the grant it received in the year 1884. Mr. Treat proposes, if he is successful in this suit, developing the foreshore in question for its coal. From the provincial standpoint, its interest is to maintain the validity of its lease and to establish its authority to give such title. If the effort fails it follows that the company will have possession of all the foreshore on the east coast of the Island from Esquimalt to Nanaimo, a distance practically (as the crow flies) of 80 miles and of indeterminate extent if the undulations of the shore line are followed.

There are two other cases of a similar character; the Esquimalt & Nanaimo Ry. Co., vs Dunlap, and Esquimalt & Nanaimo Ry. Co. vs Wilson & McKenzie (Ganner estate) These Crown grants to coal rights within the railway belt were issued to the defendants by the provincial Gvernment in accordance with the terms of the Settlers Rights Act, 1917, during the interval elapsing between the passage of the act by the provincial Legislature and its disallowance almost a year later by the Dominion. The position taken by the company is that the grants were vetoed automatically with the disallowance. If this is not controverted it is likely to have a serious effect on a large and important island enterprise of recent date, that of the Granby Consolidated Mining and Smelting Company, at Cassidy's Landing. This company has a producing mine provided with modern plant and equipment; furthermore coke ovens, at Anyox, B. C., nearly completed will depend for their supply of coal on the Cassidy colliery.

Meanwhile the agitation among the settlers of the E. & N. Ry. belt continues. A deputation of residents of the Newcastle district recently waited on John Oliver, premier, and Wm. Sloan, minister of mines, to ask what action would be taken to secure their coal rights to them. The provincial legislation of 1917 was disallowed at Ottawa and the Lieut-Governor refused his assent to the re-enacted measure of 1918. The Newcastle delegation was informed that, in view of this and what has since transpired, there seemed little reason to believe that the 1918 legislation would be allowed; the chances of their obtaining title to their coal rights appeared to be slim. There are 180 settlers affected. These people now propose directing their representations to Ottawa and a general meeting of protest is to be held at Nanaimo, B. C., shortly.

PENNSYLVANIA

Anthracite

Lebanon—Lebanon County Commissioners have increased the assessment on the 7228 acres of land held by the Philadelphia & Reading Coal and Iron Co. in Lebanon County from $20 per acre or $144,560 to $142,000,000.

Wilkes-Barre — Frank Carichner, aged 35, of 49 Keith St., and his brother Hugh Carichner were killed at the Mineral Spring colliery of the Lehigh Valley Coal Co,. on May 21. The men had prepared a shot which exploded prematurely.

Tamaqua—Fire of an unknown origin has been discovered in the No. 4, mine of the Lehigh Coal and Navigation Co. It is having no serious effect upon production and officials state that indications point to the flames being under control.

Ashland — The Locust dale washery, operated by Thorne, Neale & Co., with main offices in Philadelphia, resumed operations the middle of May, after an idleness of several months. The property lies on the Philadelphia & Reading railroad a few miles west of this place.

Miners Mills—At a conference of representatives of the Wilkes-Barre Connecting Railroad, Miners Mills Borough and Healey Coal Co., Conlon Coal Co., and the Hudson Co., with engineer Krouse of the Public Service Commission on May 21, it was agreed that it would not be safe to proceed with the construction of a viaduct over the railroad tracks, owing to the menace of mine caves.

Sunbury—Northumberland County's anthracite coal land assessments for county taxable purposes will be given a substantial revision upward, according to the present plans of the County Commissioners. It is generally accepted in official circles, although not admitted by the commissioners, that anthracite coal land values will be advanced approximately $50,000,000 for the next three years.

Shamokin—The injunction filed in the courts of Northumberland County by C. J. Golden, president of district No. 9, U. M. W. of A., and several other members of Shamokin, against moving the district office from Shamokin to Shenandoah, has been withdrawn, the objectors paying the costs. At the district convention in Mahanoy City last November the convention approved the action of the district board in the matter.

Scranton—The enlargement and rearrangement of the Carbondale yard of the Delaware & Hudson company has been progressing for several years. This yard is one of the most important facilities in the operation of this coal road, as it is located at the concentration point of all northward bound anthracite passing over the company's lines, and the distribution point of all empties returning to the collieries. Carbondale is at the extreme north end of the Lackawanna coal basin and the D. & H. mines are distributed between this place and Plymouth, a distance of 38 miles. This yard now has an increased capacity of 50 per cent.

Nanticoke—The grievance committee of the Bliss, Truesdale, Auchincloss, and Susquehanna collieries in the Nanticoke district of the anthracite field, have decided that the mine workers of the Loomis colliery of the Delaware, Lackawanna and Western R.R. Coal Department must become members of the U. M. W. of A. by June 1, 1919. This action was taken by the grievance committee on hearing the report of the Loomis committee stating that the general committee should take immediate action on organizing the Loomis miners; otherwise the United Mine Workers are liable to be substituted by some other organization that does not approve of the present method of negotiating agreements and adjusting grievances.

Shenandoah—The Lehigh Valley Coal Co., on May 19, announced important changes of officials at Packer Nos. 4 and 5 colleries. Reuben Ball, for twenty years general foreman at Packer No. 4, has been placed on the pension list, on account of failing health. Richard Kane, inside foreman at No. 3, succeeds Mr. Ball. John Rudd, assistant inside foreman at No. 4, is promoted to the foremanship at No. 3.

The Girard Water Company, owned by the estate of Stephen Girard, has let a contract to the Central Construction Co., of Harrisburg, for the construction of an additional reservoir near Ringtown, not far from this place. The dam, which will cost approximately $200,000, will be completed in about eight months, and when it is put into service will go far toward obviating summer water famines which have hampered collieries and communities in the Mahanoy Valley. The capacity of the reservoir will be 270,000,000 gal.; its superficial area, when full, 42 acres, and its tributary watershed 1280 acres. The maximum depth of water will be 42 ft. Water will be drawn, when needed, from this reservoir into reservoir No. 5, which has a capacity of more than 300,000,000 gal., and which serves as a storage point whence water is pumped to various reservoirs supplying mines and towns. Engineers in charge of the plans were Gannett, Seelye & Fleming, of Harrisburg, and James Archbald, of Pottsville, engineer for the Girard Water Co.

Bituminous

Charleroi—The examining board of the twenty-first bituminous district, which recently held examinations here for mine officials, announced that of the successful applicants who passed examinations, five received certificates as mine foreman, 16 as assistant mine foreman, and 20 as fire boss. The examining board included the following: Inspector C. P. Bryne, Superintendent Joseph Edwards and Michael Dooley, miners.

Altoona—Speaking at the annual meeting of the Central Pennsylvania Coal Producers' Association at this place, May 15, James H. Allport, member of the U. S. Fuel Administration and representative of the United States in investigating mining and fuel conditions in France, urged the members to "develop the export trade in coal to help the French and Italian people get on their feet and to also aid in restoring prosperity in our own country." He told of the great suffering by the Allies and by the people of the allied countries due to the lack of coal brought about by the destruction of foreign mines by the Germans. T. H. Watkins, of New York, representing the exporters' association, also urged a boost in the local operations and the increasing of exports, stating that "only America can supply this big demand from the allied countries." J. D. A. Morrow, secretary of the International Coal Producers' Association, also spoke. The following officers were elected: President, Henry Boulton, of Clearfield; vice president, M. C. Bracken, of Gallitzin; secretary, Charles O'Neill, of Clearfield, and statistician, W. A. Jones, of Hollidaysburg—all of Pennsylvania. The following are the board of directors: T. H. Watkins, of New York, M. J. Bracken, of Gallitzin, B. M. Clark, of Punxsutawney, E. B. Chase, of Philadelphia, Harry Boulton, of Clearfield, T. Larry Eyre, of West Chester, D. C. Morgan, of Kittanning, H. B. Scott, of Philipsburg, J. S. Sommerville, of Robertsdale, J. C. Cosgrove, of Johnstown, George H. Francis, of Greensburg, Thomas F. Kelley, of Coalport, Robert Summerville, of Winburne, J. William Wetter, of Philipsburg, J. R. Caseley, of Du Bois, W. R. Craig, of St. Mary's, T. V. Gould, of Brisbin, and C. H. Jacobs, of Philadelphia.

WEST VIRGINIA

Raleigh—The Raleigh Coal and Coke Co. is making improvements at its Nos. 1 and 6 mines at this place, installing loading booms, steam car dumps and other new equipment which will increase output.

Macdonald—Protest having been made by the machinists of the New River Co. to going to Mt. Hope, where the company expected to relocate its new shops, final decision on the location of this plant has been deferred for the time being.

Wheeling—Shipment of coal to Cincinnati and Louisville over the Ohio River route has been resumed, it having been several months since any coal was shipped via this route. In the first fleet which passed here on May 16 there were 15 barges in two tows, or about 250,000 bu. in all.

Shinnston—A coöperative coal mine is a scheme which gives promise of reaching the development stage at this place. There is a tract of 14 acres of coal within the corporate limits of the town susceptible of development for a municipal supply of fuel. A possible future shortage of gas confronts the town.

Fayetteville,—The Cepec mine which is owned by C. P. Galloway, of Glen Jean, is about ready for operation, construction work on this plant having just been completed. The mine is located near Kilsyth. Two Fayette County men—Dr. C. B. Lee and Thos. Nichol—have leased several hundred acres of coal land from the McKell Coal Co. which will be developed through the opening of new mines.

Charleston—Mines of the Black Betsey Consolidated Coal Co., in Putnam County, are running again, having been closed down since about Jan. 1, because of poor market conditions. These mines are under the management of T. W. Woodward.

The work on the plant of the Ingram Branch Coal Co., near Page, has progressed to such an extent that the company plans to begin the shipment of coal shortly.

Fairmont—It will be necessary in the future to discontinue furnishing cars to mines where such mines have on hand unconsigned loads, provided the situation indicates a reduced car supply. Mines in the northern part of the state have been notified that where any mine carries unconsigned loads such a mine will be subject to having its car supply discontinued whenever the increase in Lake business makes it necessary. The new order indicates a growing car shortage and is made to insure and protect such mines as are working and are billing their coal.

Bluefield—In the Pocahontas district the week ended May 10 was marked by larger gains than have been witnessed at any time in recent months, production going up to 285,000 tons, a gain of 38,000 tons over 247,000 which was the tonnage for the week ended May 3. Equally encouraging was the reduction in the production loss from 171,000 to 114,000 tons—a gain of 57,000 tons; only 88,000 tons were lost from no market as against 141,000 for the previous week—a decrease of 53,000 tons. It will thus be seen that the Pocahontas district is sharing in the increased demand for coal. Certain it is that Pocahontas coal is commanding much higher prices than was the case a few weeks ago.

Huntington—Between May 3 and 10 another gain of 15,000 tons was made in the output of the Logan district. The mines of that district reached a total of 176,000 tons or 58 per cent. of full time capacity; at the same time this tonnage was 40,000 tons under the output for the corresponding week last year when 216,000 tons were mined. There was an increase in production losses of 21,000 tons—or from 148,000 to 127,000 tons. The no market loss was cut from 131,000 to 106,000 tons—a gain of 25,000 tons in that respect. There was a

pronounced increase in the car shortage which was run up from a loss of 1100 to one of 5500 tons.

Huntington—The twentieth semi-annual meeting of the West Virginia Coal Mining Institute will be held at Hotel Frederick at this place on June 3 and 4. The following papers are scheduled: Tuesday morning. "The Future of the Coal Industry," by J. A. Hall. W. D. Roberts will lead the discussion following. Tuesday afternoon. "Is There an Overproduction of Coal in America?" by J. H. Thomas. "The Recovery of Coal," by F. G. Wood (discussion). "Labor Saving Devices," by C. R. Jones. Wednesday morning. "What Coal Operators Have Learned from the War," by E. N. Zern. "The Most Common Violations of the Department of Mines," by W. J. Heatherman. The closing session: two papers on "Coal Preparation," (a) "Inside," by C. H. Tarleton; (b) by J. W. Bischoff.

INDIANA

Linton—Jesse Bedwell, age 35, was fatally injured at the Black Creek mine near this place on May 13, by being struck on the head by a piece of coal. He suffered a fracture of the skull which resulted in his death the following day.

ILLINOIS

Springfield—The June examinations by the state Miner's Examining Board will be held at the following places and at the dates noted: Du Quoin, June 4; Herrin, 5; West Frankfort, 6; Harrisburg, 7; Christopher, 9; Belleville, 10; Litchfield, 11; Springfield, 12; Danville, 13; La Salle, 16; Peoria, 17; Rushville, 19.

Centralia—State mine inspectors, V. P. Rassbottom, J. O'Rourke and Messrs. Wright and Morgan, of Belleville, met in this place to ascertain the cause of the recent explosion in the Glenridge mine of the Marion County Coal Co. near Centralia. Four men lost their lives in the accident, fire followed the explosion and the mine was badly damaged.

Johnston City—The Johnston City Washed Coal Co., has resumed operations at its White Ash mine at this place after a shut down of several weeks. During the suspension of work at this plant, the mine was given a complete overhauling and extensive repairs were made on the shaft and tipple. It is reported that the company has secured large coal contracts for the coming year which indicates that the plant will operate steadily for some time.

KENTUCKY

Boldman—The Furnace Coal Mining Co., located at this place, is making arrangements to increase its output through the installation of electrical equipment throughout its plant, a new power house having been built and power machinery installed.

Coal Run—C. E. Steel, owner of the Coal Run Coal Company at this place and manager of the Funk Coal Co., at Sutton, Ky., has sold his interest in the former company to H. H. Funk. Operations at the Funk Coal Co.'s plant have been suspended owing to repairs which are being made, much construction work is in progress so as to fit the mines for the more extensive mining of coal when operations are resumed.

Farmers—Quite extensive development in three Kentucky counties—Morgan, Breathett and Elliott—is presaged by a large deal in which approximately 200,000 acres of coal and timber lands will change hands, E. B. Carr of Philadelphia and Geo. B. Kaywood of Frankfort having sold the property to St. Louis, Pittsburgh and Chicago capitalists for a sum which will run well into the millions. It is proposed to build a railroad through from Index to Farmers, Ky., following the Licking River, a connection being made at Farmers with the Chesapeake & Ohio.

Pikeville—The Northeast Kentucky Welfare and First Aid Association is the name under which a new organization has been formed in Kentucky, with the following officers: President, J. L. Morgan, Pikeville; vice presidents, C. A. Warden, Hellier, R. C. Thomas, Paintsville, C. E. Anderson, Hellier, K. C. Mitchell, Wolfpit, C. W. Connor, Esco, Charles M. Keyser, Keyser, N. M. White, Prestonburg, J. J. Christie, Lookout and Zach Justice, Pikeville; treasurer, Linton Trivette, Pikeville; secretary, Everett H. Sowards, Pikeville. The new association plans to hold a first-aid contest on July 4 at Pikeville.

Ashland—A special meeting of the operators of northeast Kentucky was held at this place on May 16, being featured by the presence of W. B. Reed, of Washington, D. C., accounting secretary of the National Coal Association. Approximately 50 operators of the Elkhorn and Big Sandy fields were in attendance at the meeting. Mr. Reed talked largely on the proper way to handle war revenue and income tax statements. It was suggested during the meeting that the retention of expert accountants in an advisory capacity would be of much benefit to operators. Traffic counsel will be employed by the association as the result of a report made by the special committee delegated to secure through rates via the Chesapeake & Ohio railroad to tidewater and southeastern points. New members admitted gave the Northeast Kentucky Coal Association a total membership of 74.

Obituary

Walter W. Winton, of Scranton, president of the Winton Coal Co. died of heart failure at his home on May 19. Mr. Winton was a graduate of Harvard University; he also served the Union cause in the Civil War with distinguished bravery. Besides being president of the Winton Coal Co., Mr. Winton was connected with numerous other coal companies and also with banking institutions.

W. Arthur Hitchins, president of the Hitchins Brothers Co., a director of the Hitchins-Brophy Coal Corporation and the Citizens' National Bank, died at the Mercy Hospital in Frostburg, Md., recently. Mr. Hitchins was 50 years old. He succeeded his father, the late Adam E. Hitchins, as head of the Hitchins Brothers Co. and was widely known in the industrial and coal circles of Allegheny County. Among his surviving brothers is Owen Hitchins, of New York and Howard and Emery G. Hitchins, of Frostburg who were associated with him in the Hitchins Brothers Co.

Industrial News

Grove City, Penn.—The Pittsburgh Coal Co. has recently resumed work at its coal stripping operation in Pine Township.

Indiana, Penn.—The Commercial Coal Co. is understood to be planning to increase the capacity of its properties in Black Lick Township. The present output will be practically doubled.

Riceville, Ky.—The Green Rock Coal Co. is planning for the installation of the necessary mining machinery for the development of a large local coal tract. H. D Foster is president and manager.

Jeddo, Penn.—The G. B. Markle Co. is in need of 100 miners and laborers for its Highland No. 5 and Jeddo No. 4 collieries. There is a scarcity of qualified miners in the Lehigh anthracite field at the present time.

Charleston, W. Va.—The Dana Coal Co. has leased a tract of coal, comprising about 1200 acres and located in the Maiden district; it was held by the Maiden Coal Co. The Dana company expects to develop the property.

Edwardsville, Ill.—The Donk Brothers Coal Co. is sinking a shaft at this place and planning the construction of a plant to cost about half a million dollars. When completed and running at full capacity, this operation should employ about 700 workmen.

Moundsville, W. Va.—The Dunkard Valley Coal Co. has recently completed negotiations for the purchase of a coal tract comprising about 7½ acres, located in the vicinity of this place; plans are being arranged for the commencement of operations at an early date.

Harlan, Ky.—William Helton, mine foreman, died as a result of being crushed by falling rock while opening a new mine on the lease of the Canel Bits Coal Co., in North Harlan. His leg and side were badly mashed, resulting in death shortly after reaching the hospital.

Henderson—Plans are being arranged by L. P. Kleiderer, Fourth Street, Louisville, for the inauguration of operations in the local coal mine recently acquired. In connection with the work, it is proposed to install a new shaft, provide the construction of a new coal tipple, with the installation of necessary coal mining equipment, etc.

Monongahela, Penn.—Robert Robinson, of this place, is understood to have recently completed negotiations for the purchase of the holdings of the Vulcan Coal Co., Connellsville, Penn., including about 600 acres of coal with three mines, located at Pomeroy, Ohio. It is also understood that the new owner is planning for continued operation, with increased capacity.

Fairmont, W. Va.—The Consolidation Coal Co. has completed arrangements for the opening of a new mine and the construction of a tipple fronting on the yards of the Pennsylvania Railroad, at Mingo, Ohio. It is also stated that this company recently completed negotiations for the purchase of the holdings of the Royal Coal Co. and the property of the Tarr farm adjoining, comprising about 700 acres.

Birmingham—The annual meeting of the Alabama Coal Operators' Association will be held in this place June 3, 1919. The annual reports of officers will be made, plans for the advancement of the interests of the association will be discussed and officers for the ensuing year will be elected. Consideration will be given to amendments to the constitution and by-laws of the association as proposed at the last annual meeting.

Louisville, Ky.—Traffic manager C. D. Boyd, of the Harlan County Coal Operators' Association, the Hazard Coal Operators' Exchange and the Southern Appalachian Coal Operators' Association, has requested publication of through rates to take the place of combination rates on coal from mines on the Louisville & Nashville, Queen & Crescent and short line connections to destinations on the Baltimore & Ohio R.R.

Toledo, Ohio—Considerable activity has developed at the docks and the Lake trade is gradually increasing. This is shown by the records of loadings at the docks for the week ended May 17. The Hocking Valley docks during the week loaded 12,527 cars or 176,143 tons, making a total of 652,338 tons loaded during the season. The Toledo & Ohio Central docks during the same week loaded 41,810 tons as compared with 24,558 tons the previous week, making a total of 105,342 tons for the season.

Louisville, Ky.—The Western Kentucky Coal Operator's Association met at this place in the Seelbach Hotel, to discuss plans for competing with eastern Kentucky mines, as the result of a new freight rate to Cincinnati, effective shortly. The reduced rate is said to open a new field for western Kentucky coal. Steps were also taken for contracting for the sale of coal to bunker steamships at New Orleans and Mobile. Tests are being made as to the adaptability of western Kentucky coal for this purpose.

Louisville, Ky.—The Illinois Central railroad has requested revision of rates on coal from mines in western Kentucky to Paducah, Mayfield, Fulton and intermediate points, in order to remove preferential rates on nut, slack and pea coal and to place western Kentucky and southern Illinois points on a parity. It is held that rates on steam coal should be 20c. a ton lower than on other grades and that present rates place western Kentucky mines at a disadvantage. The matter will be heard May 28 before the Louisville District Freight Traffic Committee.

Another request, set for hearing May 28, is that of the Southern Railway for publication of an advance of 10c. per ton on coal from mines on the Southern in Tennessee, Kentucky and Virgina to stations in North Carolina on the Elkin & Allegheny Railway.

Bethlehem, Penn.—The Dodson International Coal Corporation recently formed expects to handle the future export coal business of Weston Dodson & Co., Inc., of this place. The following are the officers of the new company: Alan C. Dodson, chairman of the board; Sterling J. Joyner, president; John T. Morrow and W. R. Coyle, vice-presidents; G. R. Radford, treasurer; H. W. Kessler, secretary; J. H. Davison, manager. Mr. Joyner has been identified with the export business and with engineering and construction companies. The Dodson offices in New York will be moved to the fortieth floor of the Woolworth Building and will be in general charge of J. H. Davison, as tidewater and export sales manager. Mr. Davison had been New York manager of Weston Dodson & Co., Inc., for several years prior to his entry into the service in 1917.

MARKET DEPARTMENT

EDITED BY ALEX MOSS

Weekly Review

No Activity in Soft Coal—Prices Being Maintained—Higher Prices Predicted—Output Far Behind Last Year's Figures—Anthracite in Good Demand, with Some Mines Refusing New Business

THE bituminous coal market is colorless. Most of the coal being shipped from the mines is in fulfillment of contract obligations. Operators continue to be optimistic. Coal is being sold at the prices that have been in effect for some time, with the usual reductions heard of here and there on occasional shipments. It is freely predicted that prices will be higher before long, and operators quote above the present level on contracts to the end of the coal year. Production of soft coal for the week ended May 17 is estimated at 8,383,000 net tons. How the lack of demand has curtailed the output of bituminous coal may be gathered from the fact that for the period of Jan. 1 to May 17 the production totaled 160,599,000 net tons as compared with 212,511,000 net tons for the same period of 1918.

So urgent is the request for anthracite that producers are hard put to it to meet the demand. Many of the operators already have sufficient orders on their books to keep their mines working full time well into July. A number of producers refuse to consider any new business for the present. All the domestic sizes of hard coal are eagerly sought, but the smaller steam sizes are moving slowly. During the week ended May 17 there were produced 1,743,000 net tons of anthracite. For the period Jan. 1 to May 17 the output of hard coal totaled 28,859,000 net tons as against 37,144,000 net tons in 1918.

WEEKLY COAL PRODUCTION

The production of bituminous coal in the United States during the week ended May 17 is estimated at 8,383,000 net tons, and is but slightly less than the output of the week preceding, estimated at 8,421,000 net tons. The daily average production during the week ended May 17 is placed at 1,397,000 net tons, and as during the preceding week, exceeded the daily average for the calendar year to date, estimated at 1,361,000 net tons. For the period of Jan. 1 to May 17, the production of bituminous coal in the United States is estimated at 160,599,000 net tons as compared with 212,511,000 net tons for the same period of 1918, thus placing the current year's output to date at approximately 52,000,000 net tons, at 25 per cent. below the record production for last year.

The improvement which began in the anthracite production several weeks ago continued during the week ended May 17, and while such output is slightly lower than the production during the week of May 10, it equals the weekly average during the years preceding the abnormal year of 1918. The production during this week is placed at 1,743,000 net tons, with a daily average of 290,000 net tons as compared with 245,000 net tons for the calendar year to date. As in the case of bituminous coal, anthracite production for the calendar year to date is approximately 25 per cent. below the output for the same period of 1918.

The production of beehive coke in the United States during the week ended May 17 is estimated at 209.975 net tons and considerably below the output for the week ended May 10, estimated at 260,378 net tons. The current week's production is but 33 per cent. of the output recorded during the week ended May 18, 1918, when the production of beehive coke reached the high mark of 634,056 net tons. Production in all states with the exception of West Virginia decreased during the week ended May 17 compared with the ended May 10. The decreases which occurred were slight in all states with the exception of Pennsylvania, where the production amounted to 153,781 net tons as compared with 193,830 net tons during the week ended May 10 and 458,796 net tons during the corresponding week of last year. For the calendar year to date beehive coke production is estimated at 7,964,179 net tons against 11,344,400 net tons during the same period of 1918. The average daily production during the week ended May 17 is estimated at 34,996 net tons as against 67,493 net tons, the daily average for the period Jan. 1 to date and 96,138 net tons, the average daily for the period Jan. 1 to May 18, 1918.

The dumpings of bituminous coal at the lower lake ports during the week ended May 10 are estimated at 718,366 net tons and are approximately the same as the dumpings during the corresponding week of 1918, which were placed at 723,294 net tons. For the 1919 season to date the dumpings are placed at 2,220,848 net tons and are in excess of the dumpings during the same period of last year, which amounted on May 11 to 2,046,284 net tons.

BUSINESS OPINIONS

Marshall Field & Co.—Current wholesale distribution of dry goods is running a little greater than for the corresponding week a year ago. More customers are in the market. Orders from road salesmen for both immediate and future delivery continue in exceptionally large volume, the total being nearly double that of the corresponding week of 1918. Collections are most satisfactory.

Dun's—With practically all centers reporting expansion, bank clearings at the principal cities in the United States this week attained notably high figures and surpassed all previous records for the period. The total at fifteen points amounted to no less than $7,028,308,834, an increase of 26.4 per cent. over the same week last year, and one of 39.3 per cent. in comparison with 1917.

Bradstreet's—Something like a shifting of activity is revealed in the trade and industrial reports this week. Cool, rainy weather and the lateness of some of the spring planted crops, especially corn and cotton, seem to be more stressed at the smaller markets, but increased activity, strength and confidence are revealed at the larger centers, while in instances where weather conditions have been favorable and seasonable temperatures have prevailed the trend has been a very cheerful one.

The Iron Age—Though a measurable volume of business now marks the recent ushering in of government-free trading, nowhere can it be said that the long awaited buying movement is under way. Weighing our various reports the conclusion is forced that pressure is gathering to such an extent that heavy purchasing cannot be long delayed. Concessions in price are unquestionably being made in both iron and steel, but there is no general break from what are regarded as market levels and few of the changes as yet establish a new price. There is no frantic endeavor to get business at keenly competitive prices.

Dry Goods Economist—Probably the most interesting event of the week, so far as the retailer is concerned, is the recommendation by President Wilson that the taxes upon retail sales "can hardly find justification under the easier circumstance of peace, and can now happily be got rid of." In every section activity among the retail dry goods stores is pronounced. The recent gains in the volume of sales have been well maintained and the expectation is general that an era of prosperity is at hand. Labor unrest continues in some textile centers, but the situation has been eased by the settlement of the strikes in Lawrence, Mass., and in Cohoes, N. Y.

American Wool and Cotton Reporter—Strength of the wool market still continues, but there is a decided trend toward conservatism in the trade. On the whole, in the West the buyers are inclined to hold off, prices have advanced so rapidly. Some mills are pretty well supplied with stock now and some have stopped buying for the present. Some are of the opinion that there may be a slump in wool after a while, while others feel that the strength will continue for a long time. "Stronger than ever," is practically the universal report among cotton factors in Boston in regard to the cotton market, and it is predicted that will be the report every week this summer. White cotton, especially staple, is apparently scarce.

Atlantic Seaboard

BOSTON

Market remains inactive. Receipts light. Pennsylvania grades maintain the advantage both all-rail and by water. Balance of railroad orders placed. Hampton Roads situation unchanged. Navy bids due to be opened within a few days. Scarcity of railroad barge tonnage hampers movement from New York and Philadelphia. Anthracite shipments extremely slow. Tidewater receipts far behind the demand. No limit to retail trade.

Bituminous—While there are surface indications of better buying, yet the undertone is extremely quiet. Buyers show as little interest as a month ago and there are many steam-users throughout New England who have not yet arranged for coal they are to use in August. Several large consumers who have usually drawn their supply from the Pocahontas and New River districts are still "experimenting" with grades from central Pennsylvania; there is no comprehensive buying, and aside from spot purchases of limited tonnages the bulk of contract business is still confined to specialties.

The figures show no material increase in receipts here from week to week. It is plain to the trade that the market is absorbing just about what is shipped, and were the tonnage to increase it would mean that New England was at last trying to be forehanded for the future. The strike of engineers in the textile mills of New Bedford, Mass., put 30,000 operatives out of employment and this is only one of many features of the industrial situation that

lead manufacturers to postpone buying on anything like a large scale. Even the railroads have been taking coal in very light volume. Their stocks have been large and it was only recently that arrangements were completed for the 11 months beginning May 1.

This territory shows no change from the turn given the trade early in the year when it became evident that Pennsylvania coals would have the preference. Certainly that advantage has been maintained, for not only by rail but by water from the New York piers are these grades being purchased to the virtual exclusion of the smokeless coals from Hampton Roads. The Boston & Maine R.R. has always taken at least 60 per cent. of its supply by the water route, but this year only about 20 per cent. has been arranged for other than all-rail. And of the 20 per cent. practically all has been bought from Pennsylvania or West Virginia shippers for loading at Philadelphia or New York. Recently the City of Boston bought 45,000 tons of steam coal for harbor institutions and while the contractor is a factor in Pocahontas and New River distribution yet this year the tonnage was placed on Pennsylvania coals, the differential was so much in their favor.

The railroad orders have now been practically all placed and published. Acting largely on directions from Washington the New England purchasing agents have bought in several new channels and the trade is curious to see how some of the experiments will turn out. A number of shippers who have been customary sources of supply and familiar with conditions put in bids on what they considered a fair basis only to find now that they are without any railroad orders at all.

At Hampton Roads there is no material change. Shipments to New England are very light and the sales agencies are obliged to look to Government and export requirements to keep the wheels turning. The coastwise freight market is still easy and steamers normally in this trade are still chartering for South America and occasionally for ports in the Mediterranean. Consignments for Italy are somewhat reduced. The needs there are large but it can hardly be expected that American coal will be shipped in volume until certain kinks are taken out of the political situation between Rome and Paris. The local distributors of Pocahontas and New River are about discouraged over the outlook here for any comprehensive business this season. Rates are now all against Hampton Roads loading, so far as New England is concerned and something radical will have to be done before this situation can be corrected. In a year of light consumption it is possible that this territory will be able to keep running on Pennsylvania coal, but a year of normal activity would doubtless make a different showing.

As the season advances it grows more apparent that there is a real shortage of railroad-owned barges for commercial use. There is a large amount of carrying space in the hands of private owners but naturally under the conditions that prevail the latter are interested only in the most favorable movement, as from New York to Providence on to Boston. One result is the narrowing of other shipments to such railroad-owned barges as may be available and the supply of these has been very much curtailed by the attitude of the Railroad Administration in seeking to reserve a large part of this space for the transportation of railroad fuel. The principal reason seems to be that it is desirable transportation and low-priced; therefore it must be saved for the railroads. It is very difficult on that account to arrange for bituminous deliveries by water when the destination is a point east of Boston.

Current quotations on bituminous at wholesale are about as follows:

	Clearfields	Cambrias and Somersets
F.o.b. mines, net tons	$2.15@2.75	$2.75@3.35
F.o.b. Philadelphia, gross tons	4.27@4.95	4.95@5.50
F.o.b. New York, gross tons	4.62@5.29	5.29@5.85
Alongside Boston (water coal), gross tons	6.10@6.85	6.90@7.35

Georges Creek is quoted at $3.20 per net ton f.o.b. mines.

Pocahontas and New River are being quoted at $4.69@5.14 per gross ton f.o.b. Norfolk and Newport News, Va. Alongside Boston the same grades are being offered at a range of from $6.89@7.24, and on cars Boston and Providence at from $7.60@7.90 per gross ton, the latter being the contract price f.o.b cars for season delivery.

Anthracite—The same situation on railroad-owned barges has a bearing on the volume of domestic sizes that can come forward by water to New England points. Receipts are still much in arrears and retail demand shows no sign of slackening. The way the public is trying to get in its coal for next winter's use is something extraordinary; the persistency with which retail dealers continue to advertise is only more so. To have the householder put his order in early is of itself a great advantage to the retailer provided the latter can get his supply in regular monthly proportions or in quantity sufficient to keep his equipment busy. Neither all-rail or by water are shipments sufficient to meet this unusual situation and there only remains the hope that by August or September wholesale deliveries will have begun to catch up with the demand on the retailer.

NEW YORK

Demand for anthracite increases and operators have orders sufficient to carry them into July. Some shippers refusing new business. Serious shortage forecasted for next winter. Retail dealers wish for heavier shipments. Stove coal in heaviest demand. Bituminous tidewater market dull and prices easy. Plenty of coal at the docks, but spot sales are slow. Contract coals move rapidly.

Anthracite—There is an increase in the demand for the domestic sizes of anthracite which the producers are trying hard to meet. Most shippers have orders sufficient to carry them into July, while some refuse to accept any new business. Handlers of so-called independent coals in some instances have been instructed not to accept any more orders for the present.

Producers and distributors are endeavoring to make shipments equitably, but there is a lot of complaint. Business picked up considerably the lask week of this month, when dealers endeavored to place many new orders in an effort to save the regular monthly advance of 10c. per ton on the price of domestic coals.

Demand is heavy along the line with about an equal call for the various domestic sizes, and the dealers, according to report, appear to be better stocked up than those dependent upon tidewater coal. Locally the size most wanted is stove, but dealers are taking any size they can get. Egg and chestnut are selling rapidly and there is no accumulation. Pea coal, which is usually quiet in this market, is in heavy call and retail dealers are accepting all they can get so long as it enables them to obtain a proportionate share of the larger sizes. Straight orders for pea coal, however, are scarce.

The steam sizes are moving slowly. As is to be expected, these coals are plentiful but are not a drug on the market. Buckwheat is selling well and prices are holding firm. At times slight concessions are heard of, but these are on the poorer grades or on washery coals. Rice is in better supply and at times hard to move. The accumulation of barley is heavy and shippers are experiencing some trouble in keeping it down. Prices are generally held close to circular but, as with rice, slight concessions are made, especially on the so-called independent product.

The retail situation is interesting, first because of the heavy call for deliveries, and second, because of the launching of a new corporation composed in most part of local retail dealers. The new corporation, which will be known as William Farrell & Son, Inc., expects to begin business on June 1 with a tonnage of nearly three million tons. It has taken over the businesses of nine local dealers and one dealer in Jersey City, altogether operating 15 yards. In addition one wholesale firm is in the corporation. Since the formation of the new corporation there have been rumors that other local dealers are contemplating another combine. There are remaining in Manhattan and The Bronx about 40 retail yards.

Because of the high prices submitted in proposals the city departments are seeking permission from the Board of Aldermen to go into the open market for their fuel supplies. Bids were recently opened for furnishing and delivering a couple of hundred thousand tons of coal to twelve city departments. Because the prices submitted were "in excess of the current open market price, and in nearly all cases are higher than the allowances made in the budget to the departments" the Central Purchasing Committee believes a saving would be made by buying in the open market. While the committee complains of the high prices submitted, the dealers say that the specifications of the contracts contain penalties that are too severe.

At the recent opening of bids prices submitted for furnishing and delivering pea coal to the Police Department ranged from $9.98 to $11.25 per ton, depending upon place of delivery; and egg coal from $10.98 to $13.43.

For furnishing stove coal to the Department of Public Charities the prices submitted ranged from $10.97 to $12.89, according to place of delivery; buckwheat coal, $6.99 to $8.27; run-of-mine, $5.75 to $6.55; mixed coal, $6.98 to $7.59, and for furnishing the department with 2060 tons of buckwheat No. 2, the prices submitted ranged from $7.23 to $7.89 per ton.

For supplying the Fire Department with egg coal the prices submitted ranged from $12.45 to $12.99 per ton and for supplying chestnut coal from $12.77 to $13.18 per ton.

Current quotations, white ash, per gross ton, at the mine and f.o.b. tidewater at the lower ports, are as follows:

	Mine	Company Circular
Broken	$6.05	$7.90
Egg	5.95	7.80
Stove	6.20	8.05
Chestnut	6.30	8.15
Pea	4.90	6.65
Buckwheat	3.40	5.15
Rice	2.75	4.50
Barley	2.25	4.00

Bituminous—The local situation is practically colorless. Demand is slow and comparatively little spot coal is moving. There is a good movement on contract coal and indications point to an increase in this tonnage. Buying of coal in the spot market is not as active as it was a few weeks ago. Some of the pools, especially those containing the cheaper grades, are over-run and quotations for some pool coals are considerably lower than the mine basis.

Quotations for the various grades of coal for contract show no apparent change, but for spot delivery at the mine there has been some reductions for certain grades. The same coals in the various tidewater pools are being quoted at still lower prices, based on mine delivery.

The dealers continue to be optimistic as to the future notwithstanding the present situation. They look for a much stronger market within the next few weeks, with stronger prices. The local houses receive many inquiries as to future prospects and quotations for coal on contract. Much interest is being taken in the prices at which the railroads are securing their fuel supply. Operators are not so willing to make contracts running into next April and appear to be more conservative as to tying up their tonnages.

Quotations heard on pool coal follow: Pool No. 9, $2.50, mine price; Pool No. 10, $2.25; Pool No. 11, $2 and Pool No. 71, $2.75.

Quotations on the various grades, mine price, for spot and contract delivery, range as follows:

	Spot	Contract
South Forks	$2.90@$3.25	$2.95@$3.50
Cambria County (good)	2.75@ 2.95	2.95@ 3.25
Clearfield County (good)	2.50@ 2.75	2.80@ 2.95
Reynoldsville	2.50@ 2.75	2.75@ 2.95
Quemahoning	2.65@ 2.85	2.95@ 3.10
Somerset County (best)	2.50@ 2.75	2.95@ 3.10
Somerset County (poor)	2.00@ 2.35	2.50@ 2.75
Western Maryland	2.25@ 2.50	2.50@ 2.75
Fairmont	2.00@ 2.25	2.35@ 2.50
Latrobe	2.10@ 2.25	2.25@ 2.40
Greensburg	2.25@ 2.35	2.35@ 2.60
Westmoreland ¾-in.	2.60@ 2.75	2.60@ 2.75
Westmoreland run-of-mine	2.35@ 2.60	2.35@ 2.65

PHILADELPHIA

Anthracite demand continues, although consumers' orders fall off. Housing problem holds back many spring orders. Shippers swamped with orders and are trying to allot production. Hints of higher prices from June on by some shippers. Stove and nut in greatest demand, with egg scarce and pea showing surprising strength. Steam coal better, if anything. Bituminous shows little change. Railroads still after fuel at their own price. Little change in prices.

Anthracite—This week saw a slowing up in the ordering of coal at retail. The dealers report that comparatively little new business was received by them during the past week. The housing proposition has kept many buyers who formerly placed their orders each spring from ordering their next winter s supply. The dealers, however, have thousands of tons on their books undelivered and their appeals to the shippers of coal continue.

All shippers realize their inability to satisfy their trade at this time, and most of them are working out systems of distribution usually based on obligations of other years. Early in the year it was expected

that when April arrived there would be much shifting of trade. The dealers appeared to be quite willing to make new connections among the shippers, and it was noticeable that the representatives of the different houses accepted considerable new business, possibly because they feared the loss of some of the old. When the situation suddenly changed and the demand for the family sizes became out of all proportion to the production, it was these new connections that brought most of the discontent.

The big companies are simply swamped with orders for egg, stove and nut, and at least one of them is refusing all additional business until some reduction can be made in the accumulation of orders. No doubt the individual operators also hold orders out of all proportion to their ability to ship within a few weeks, but we believe that most of the dealers are worrying about the prices they will be asked to pay the smaller operators next fall and winter. Undoubtedly they are dreading premiums, and not without reason. We have in mind a half dozen houses who have already announced their intention of advancing their prices on egg, stove and nut 15c. per ton each month until September inclusive, instead of 10c. as planned by the companies. There are many high in the trade who predict that prices will go beyond that schedule by the time the snow flies.

While egg is short here there is not the urgent demand, as for stove and nut, but that is only because there is less call for it at any time in this market. Stove is not arriving in sufficient quantities to make any impression on the orders on hand, and the appeals for it continue more urgent than ever. Chestnut, too, is most active, and it will require substantial shipments to care for the business already recorded. By the middle of the present month sufficient orders had been accepted for both stove and chestnut by more than one shipper to care for the prospective production up to the end of June. Pea has been a surprise because the call for it has been beyond the expectation of more than one shipper. A number of sales for heavy tonnages at considerably reduced prices were made a few weeks ago, and purchasers are congratulating themselves and even fearing they might not receive the tonnage they arranged for at the reduced price quoted. Certainly the sellers were premature with these offers and are now refusing to duplicate them. Had they waited a short time the coal would undoubtedly have brought a higher price. It begins to look now as if the great bargains in this size which had been expected would not be available during July and August. We know that all shippers of high-grade pea coal are comfortably filled with orders, at least for the present.

Many of the dealers who had anticipated stocking heavily on nut coal are fast becoming dubious as to their ability to secure any surplus beyond their current needs. Many of them are actually displaying an inclination to take all the pea coal they can get, which is exactly opposite to their former intention. With the probabilities of a coal shortage next winter there can be no doubt that the man with a big pile of pea coal on hand will have an asset that will mean many dollars to him at a time when the people will be glad to take any size of coal.

The steam sizes are showing more signs of strength, and it is predicted by some that soft coal will before long come into its own and that the demand for all good grades will be so great that the anthracite steam sizes will be actively benefited. The larger shippers report consigning only a light tonnage of the small sizes to the storage yards during the past week.

Local dealers are not displaying more than ordinary interest in the proposed law making 2000 lb. the legal weight of a ton in this state instead of 2240 lb., as now in effect. Some of the newspapers have started an agitation that it would actually mean an increase in the price of coal, as there is nothing to compel the dealers to reduce their prices in the event of the law passing. As there is nothing in the new law compelling the shippers to use the net ton, it is presumed that they will continue to base their prices and make shipments on the gross ton. Certainly to use the net ton all around, including freight rates, would greatly facilitate the clerical work in connection with the coal business, and probably for this reason more than anything else most dealers favor it. There is also the additional reason that it would put an end to the criticism as to the high prices of coal locally as compared with other states, most of which use the net ton, but which fact is usually overlooked by the critics.

Bituminous—It is difficult to form an estimate of the bituminous trade. Some shippers report one day that there seems to be an improvement in the outlook, only to be followed the next day with the statement that the conditions are far from promising. Of course, some coal is being sold, principally on contract commitments.

The railroads, while they have closed for a considerable tonnage, are still in the market for increased shipments, but continue in the attitude of wanting to make their own price. Inquiries from industrial plants for contract figures continue to come into the offices and with an occasional fair order being booked.

BALTIMORE

Sufficient bituminous and demand is light. Anthracite in good demand, with dealers unable to fill all orders. Export shipments show increase.

The bituminous market in Baltimore is far from stable, and while there is sufficient coal to handle the situation as far as spot business goes, the demand is light and there is no contracting. Buyers refuse to go in for contracts with the spot market lower than the contract figure and appear content to obtain from time to time what their urgent demands require.

With the better grade of coals quoted at from $2.40 to $2.50 for spot sales, the demand was light. There was plenty of good coal here, and for the medium and cheap grades the prices also were low with a few sales on the former and practically no business worth while on the poor grade. The local market finds little business for poor fuels. For the medium fuels the figure was placed around $2.30 and down to $2.20. The lowest grade of coals brought $2 and under, a few sales being recorded at $1.90.

Dealers in anthracite are still complaining about the lack of hard coal to fill orders. At all of the big local quarters the transportation equipment is only in use part of the time because of lack of coals. Many of the firms are behind on April orders and do not expect at the present rate of receipts to be able to get their files emptied of April business until far into June. It is practically assured that July 1 will see an addition of 25c. to the retail price of hard coal. This is being talked of strongly, and in this way dealers hope to be able to recoup their losses sustained by the May and June increase of 10c. per ton per month.

The export business in bituminous bids fair to show some increase, not exactly on contracts, but in spot business. Vessels loading for the Italian Government, South America, Holland and Sweden are in port. Coal to the amount of 12,197 tons was shipped in cargo during the week.

Lake Markets

PITTSBURGH

Demand stationary. Slack softer. Contracts on firmer basis.

On the whole there has been no improvement in demand for coal in the past week, but the improved condition previously reported is maintained. Operations in the Pittsburgh district are at fully 50 per cent. of capacity, and this is regarded as a good showing in the circumstances, with industrial activity distinctly below normal and some consumers still in possession of considerable reserves, upon which they are drawing.

In the steel industry consumption of coal is somewhat lighter, and it is distinctly below the rate of consumption in April, since in that month the steel mills ran at an average of 65 per cent. of capacity, while at present they are hardly doing better than 55 per cent. There has been a slight improvement in the steel market in the past fortnight, but this can hardly do more than arrest the decline in production that had been occurring through the gradual exhaustion of old orders.

In the matter of coal prices there are somewhat mixed trends. There is developing more softness in slack while there is a stronger tone as to contracts to the end of the coal year. The weakness in slack is a local and ephemeral affair, due to heavier production on account of the large lake shipments now in progress, while the firmness as to contracts is due to more hopeful appraisals of the industrial future generally during the remainder of the year. Coal operators regard it as significant that commodity prices in general show practically no declining tendency and see no reason why they should not take this fact into consideration in connection with their own sales policies.

We quote the market unchanged from last week, but would note that slack is somewhat easier: Best grades gas coal: Slack, $1.80@2; mine-run, $2.35; ¾-in., $2.50@2.60; 1¼-in., $2.60@2.70; Steam: Slack, $1.70@1.80; mine-run, $1.90@2.35, all per net ton at mine, Pittsburgh district.

TORONTO

Domestic coal much in demand. Dealers continue behind in deliveries. Stocks on hand light and little arriving. Soft coal not much in requisition.

Conditions of the coal trade show practically no change, and are similar to those which prevailed during the greater part of last year. Consumers of anthracite are desirous of laying in stocks, fearing a shortage as well as a rise in prices, and dealers are far behind in deliveries. The shipments coming in from the mines are quite inadequate to meet the demand, stocks on hand are very light and local deliveries are mostly being made from the cars. There is no improvement in the call for bituminous, many of the plants in the metal trade being idle or running at reduced capacity, owing to the strike of metal workers.

Quotations for short tons are as follows:

Retail:	
Anthracite, egg, stove, nut and grate	$11.50
Pea	10.00
Bituminous steam	8.25
Slack	7.25
Domestic lump	10.00
Cannel	11.50
Wholesale f.o.b. cars at destination:	
Three-quarter lump	6.00
Slack	4.75 to 5.00

BUFFALO

Bituminous trade still quiet. Only here and there a stir. Consumers still refuse to stock up. Waiting for business to move. Anthracite much below the demand.

Bituminous—Some shippers report an improvement, but the trade is much the same as it has been. Regret is expressed over the breaking down of the slack prices. Allegheny Valley operators allege that it was done by the Pittsburgh shippers. Some improvement is reported in the Canadian trade, but as a rule consumption has run down there more than it has here.

The demand for anthracite might contribute to a car shortage if bituminous were moving at the same rate, especially as Buffalo is now sending 500 cars of grain to tidewater daily. The light demand for bituminous makes it hard to manage the output of steam sizes of anthracite, for only bituminous prices can be obtained for them. It was advocated at the retail coal convention here last week that a general effort should be made to use small anthracite sizes in the domestic trade, so as not to drive them into the bituminous trade, where they are not wanted.

Bituminous prices are rather weak at former figures, $4.65 for thin-vein Allegheny Valley sizes, $4.45 for Pittsburgh and No. 8 lump, $4.20 for same mine-run and $3.80 for all slack, per net ton, f.o.b. Buffalo.

Anthracite—The trade is active. Consumers failing to get their orders filled promptly seem to imagine that the old shortage has returned and are insisting on deliveries. This the shippers cannot comply with if they reserve any for the lake trade. While shippers do not wish to cut the local and all-rail trade short, they know that it will not answer to neglect lake shipments, for when the fall comes the coal cannot be moved at will. There would be vessels enough to load it, but the mines could not turn it out.

Anthracite shipments by lake continue to decline on account of the demand locally and all-rail to the West and Canada. For the week the amount was 88,926 net tons, of which 55,726 tons cleared for Duluth-Superior, 18,600 tons for Chicago, 10,000 tons for Sheboygan, 3200 tons for Fort William and 1400 tons for Portage. Freight rates are 42½c. to Duluth, Fort William and Portage; 47½c. to Sheboygan and 52½c. to 60c. to Chicago.

CLEVELAND

Operators say the market has developed a decided upward trend. Not only is the outlook for immediate increased demand the brightest in months, but prices have stiffened. With the feeling that price revision upward is close at hand, operators are not so anxious to sell as they have been.

Bituminous—So far as demand and prices

are concerned, Cleveland coal interests have become rank optimists. The fog of uncertainty seems to have lifted, disclosing a vast amount of business that disagreement at Washington has kept under cover. Iron and steel interests—the largest single user of steam coal in northern Ohio—are resuming operations, and their order books are growing daily. Already, steam-coal users are showing a more lively interest in the market, although buying has not improved to a marked degree so far.

With the outlook for a broadening field for the surplus slack quite bright, operators are less disposed to offer bargain prices. Prepared sizes, too, have taken on strength. Mine-run continues to rule at slightly more than $2 a ton, with prepared sizes around $2.30 to $2.40. Operators who failed to land railroad fuel contracts now are more than pleased, for a $2.10 or $2.15 contract does not look so attractive in the light of developments the last few days.

Domestic consumers are still taking all of the Pocahontas and anthracite they can get. Dealers are wondering if this coal year will repeat itself; whether they will do a winter business this summer and a summer business next winter. A surprising tonnage is being absorbed by domestic users, especially when holdover stocks of domestc bituminous were supposed to be quite large.

Lake Trade—The trade has lost some of the speed with which it opened the season, due more to the scarcity of cargo space than to decreased demand or supply. The tonnage of bituminous at Lake Erie docks continues in excess of freighter capacity. This is due to the slow opening of the iron-ore season—a condition reviving business is expected to remedy shortly.

Prices of coal per net ton delivered in Cleveland are:

Anthracite:	
Egg	$10.85@10.95
Chestnut	11.15@11.25
Grate	10.95
Stove	11.05@11.15
Pocahontas:	
Forked	8.85
Lump	8.00
Mine-run	7.20
Domestic Bituminous:	
West Virginia splint	7.30@ 7.40
No. 8 Pittsburgh	6.10@ 6.35
Massillon lump	7.30@ 7.40
Steam coal:	
No. 6 slack	4.20@ 4.40
No. 8 slack	4.60@ 4.85
Youghiogheny	4.90@ 5.10
No. 8, ¾-in.	5.35@ 5.50
No. 6 mine-run	4.40@ 4.50
No. 8 mine-run	4.70@ 4.85

DETROIT

Sales of bituminous continue to fall short of normal, arousing apprehension of uncertain supply later.

Bituminous—Persistency of the users of bituminous coal in holding off on placing orders is reflected in the meager volume of business coming to wholesalers and jobbers in the Detroit market. The unwillingness of buyers to make provision now for future requirements creates a very unsatisfactory situation in the bituminous trade and occasions considerable anxiety to jobbers who have studied the general condition of the market.

The assertion is made that a reaction is almost certain to come, probably late in the summer, and that there will then be seen a grand scramble among consumers of steam coal to cover their requirements for the coming winter. It will be impossible, the jobbers say, for the producers to satisfy all consumers in the limited time that will be available, and the result, it is feared, will be that many of the buyers will not get all the coal they need. Jobbers emphasize the contention that should such a contingency arise, the buyers will have only themselves to blame, but probably will try to attach the responsibility to the coal men.

The expectation of lower prices, the jobbers insist, is certain to meet with disappointment. Instead there is said to be substantial basis for the belief prices will be higher than now, with transportation conditions less favorable for assuring prompt delivery of shipments.

Prices on West Virginia splint or gas lump at the mine, net ton basis, are quoted as $2.75; for three-quarter lump, $2.50; for run-of-mine, $2.10 to $2.25; for slack, $1.85. On the same basis, Hocking domestic lump is quoted $2.50; mine-run, $2, and slack, $1.50. Other leading varieties of Ohio coal are said to hold about the same level as Hocking. Smokeless is not very plentiful. Lump and egg is practically out of the market, with prices at $3.50 to $4, while mine-run is obtainable at $2.75.

Anthracite—Retail dealers are making a diligent effort to accomplish an early distribution of anthracite among household consumers. The latter, however, are less receptive than would be expected following the experience of the last two seasons.

Lake Trade—Coal for the lake trade is moving rather freely. Shipments for the week ending May 17 are reported as 860,880 tons, the highest for one week so far this season.

COLUMBUS

A better feeling is shown in every branch of the coal trade. Demand from manufacturing plants is increasing and there is also an increasing lake movement. Some stir in domestic trade is reported. The screenings market is still soft.

The coal trade in Ohio is getting better from day to day. Buying is on a more liberal basis and purchasers are in the market for quotations. Since the award of the railroad fuel contracts the situation has cleared to a large degree, and many coalmen predict an upturn in the market. With the exception of screenings there is a better demand for all grades of coal, and in some instances premiums are being offered for shipment.

The steam trade is now attracting the attention of coalmen. There is a better demand for mine-run and other sizes except screenings. Reserve stocks in the hands of consumers are gradually being reduced to a point where they will be compelled to come into the market soon. This applies especially to general manufacturing lines. Rubber plants still have a considerable surplus and the same is true of iron and steel concerns. But the steam situation is better than formerly, and there are a larger number of inquiries received from concerns which are about to start up. Railroads are taking a larger tonnage than formerly.

The lake trade is progressing satisfactorily as far as concerns having their own dock connections is concerned. A fair tonnage is moving from Ohio and West Virginia mines to the Northwest. Vessel rates have now been fixed at 42½c. from Ohio and Pennsylvania ports to the head of the lakes. Lake agreements for tonnage have been made with the prices left blank. Shipments have been made on these agreements. Some little mine-run is being shipped to the lakes but the large majority is prepared sizes.

The domestic trade is showing up more actively with some retailers in the market. This applies especially to the fancy grades such as Pocahontas and West Virginia splints. Little Hocking coal is being stocked. Prices for the fancy grades are exceedingly high and recent advances have all been maintained.

CINCINNATI

Everything is quiet. Reduction in the price of anthracite is expected to stimulate buying.

The coal situation here is still quiet. Large coal dealers report that business is only fair, and that the demands for the different grades continue to remain far below normal. There was, however, a decrease in the price of some kinds of coal that might stimulate trade somewhat; anthracite, formerly priced for this locality at $12.50 for chestnut and egg per ton, has taken a drop to $11.75 and $12. Domestic egg coke has also taken a drop from $11.50 per ton to $9.35 and $9.45. Smokeless grades, for which there has been a heavy demand here lately, has increased in price. This coal, which has been quoted at $7 and $7.25, has been increased to $7 and $7.50.

The Ohio Valley Coal Operators Association has petitioned the Louisville District Freight Traffic Committee for through rates on coal from mines in western Kentucky to southwestern territory, and a hearing has been set for June 5.

LOUISVILLE

General business showing improvement, with slightly better steam demand; stocking orders for domestic increasing. Prices on domestic coal firm, but spot steam-coal prices are weak and cover a wide range.

Bad weather during the greater part of the past month has been an incentive to early stocking, although it has not produced much actual business, as the domestic consumer has been able to keep warm with gas. However, stocking orders have been coming in somewhat better, and while retailers generally state that business is dull, they are operating a much larger percentage of their delivery equipment and are buying more freely from the mines.

Jobbers report a fair movement of coal into some Southern districts, and also to the lake region, with steam draggy, but mine-run picking up and domestic or prepared sizes in good demand at strong prices. Notices have been received by jobbers and retailers of further price advances about June 1, on numerous grades of block coal. North of the Ohio there is a steadily increasing demand from dealers, principally in Ohio, Indiana, Illinois, Michigan and Minnesota, while Kentucky consumption is holding up nicely.

The producers of eastern Kentucky are feeling much better over improved conditions, reporting a 70 per cent. or better production, with full supplies of labor and cars. Block coal is in strong demand, with markets steadily advancing; mine-run is better. Getting rid of spot screenings has not been easy with steam plants. Contract prices as a whole are firm, however, and several good contracts have been closed. The Louisville & Nashville R.R. has closed most of its contracts, and the Big Four lines recently closed contracts with West Virginia and eastern Kentucky mining concerns at prices ranging from $1.88 to $2.25 for the most part.

The following prices are being quoted by Kentucky districts, less 15c. per ton brokerage, and plus 15 to 30c. a ton on contracts.

Elkhorn and Harlan—Block, $3 to $3.10; mine-run, $2.40; nut and slack, $1.60. Hazard—Block, $3; mine-run, $2.40; nut and slack, $1.60. Jellico—Block, $3.25 at $3.40; mine-run, $2.40 at $2.50; nut and slack, $1.90. Straight Creek—Block, $3 at $3.15; mine-run, $2.40; nut and slack, $1.75. Western Kentucky—Lump, $2.20 at $2.60; mine-run, $2 at $2.35; nut and slack, $1.60 at $1.75; thin screenings, $1.40. Blue Gem—Block, $3.50.

There is a considerable range in some of the prices, but the foregoing figures are as close as can be had. Some Hazard block is reported as low as $2.50 and up to $3.25, or an average of $2.76, with mine-run selling at $2.40@2.90, and nut and slack, $1.50@2.75. Wide ranges are due largely to tipple and wagon operations, and good grades as compared with grades from poorer mines in the same field.

BIRMINGHAM

Slightly improved condition in coal trade, with some contracts closed for steam fuel. Domestic situation tight, with tendency for advance in price of all grades. Production shows falling off of some 25,000 tons, as compared with previous week.

Some contracting was done for steam fuel during the past week by cotton oil mills and ice factories to cover requirements for the coming summer and fall, and while inquiries are somewhat better, other classes of consumers are still holding off from actual buying, business being confined to scattering small orders. Lack of vessels for caring for foreign trade is undoubtedly hindering the consummation of some deals for coal from this district, as inquiries are being received almost daily from some foreign territory; and as soon as bottoms are provided, rates adjusted and some other details arranged some good orders will more than likely be booked by local coal men.

The demand for domestic coal is sharp and the shortage is already pronounced in the better grades, while production of the medium and lower grades is still held down by the lack of orders for steam grades. Cahaba operators have advanced prices on lump and nut from $3.85 to $4.25 and $4.75—those who have not entirely sold up their production through the remainder of the year. Corona lump and nut has advanced from $3.40 to $3.65 per net ton mines during the past week, and on account of the scarcity of all domestic fuel prices are expected to steadily climb as the demand increases with the approach of fall and winter.

Coke

CONNELLSVILLE

Spot furnace and foundry coke stiffer. Uncertainty whether furnaces will close second half contracts. Production very light.

On the one hand spot furnace coke cannot be picked up at as low prices as formerly, while on the other hand there are rumors of large numbers of loaded cars held on track because the holders will not accept prices consumers would offer. As the time for making second half contracts has practically arrived, the operators may be engaged in an effort to produce a strong spot market for the favorable influence this

would exert upon contract prices; but in this they may be reckoning without their hosts, since the furnaces that buy coke have scarcely any pig iron sold ahead and may prove quite indisposed to take hold for a six month's period even at price concessions. The attitude of the merchant furnaces is that they do not want to run unless they can make a profit. Pig iron prices are very high, and so are pig iron production costs, and the furnaces would rather see a margin of profit made for them by a decline in production costs than by an increase in selling prices. While the operators expect to close second half contracts in the next few weeks, it is not certain that they will be able to do so.

The whole coke situation, at best, has become a narrow affair. While the merchant ovens in the Connellsville and Lower Connellsville region averaged more than 140,000 tons a week production from the middle of March last year until the end of October, their production lately has been averaging less than 45,000 tons a week, or about 30 per cent. as much. The furnace ovens show a still greater decrease approximately from a 190,000 ton average to a 40,000 ton average, whereby they are making only about 20 per cent. as much coke as formerly. This great decline is due to the fact that the decreased consumption falls almost entirely upon the Connellsville region, the byproduct ovens at the various furnace plants remaining in almost full operation.

Spot furnace coke is usually quoted at $4, but $3.75 might possibly be done in some cases. Spot foundry coke has stiffened, common brands formerly obtainable at $4.25 now bringing $4.50, while recognized standard brands readily bring their former prices, up to $5. Thus the spot market is quotable at $3.75@4 for furnace and at $4.50@5 for foundry, per net ton at ovens.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended May 17 at 83,284 tons, a decrease of 17,696 tons.

Buffalo—An effort is being made to establish a trade here in high-grade coke for domestic use in various sizes at $7.10 per net ton f.o.b. here. The scarcity of anthracite favors it somewhat, though the low price of bituminous makes it impossible to sell coke breeze. The quoted price of 72-hour Connellsville foundry is $7.25 to $7.50; for 48-hour furnace, $6.60; and for off grades, $6. There is no improvement in the demand for iron ore, the amount coming down by lake still being small.

Middle Western

GENERAL REVIEW

Business dull, in spite of small improvements. Belief is growing that there will be a shortage of coal this fall and winter.

Business in Illinois and Indiana continues very dull, in spite of some small improvements. Coal is moving but slowly on current orders, both steam and domestic. Some business, calling for future shipments, has been reported, but not very much. The tendency on the part of the coal dealer to contract is growing, and an encouraging number of closed contracts have already been reported, with more to follow. The buying public, as yet, are not aware of their danger, and they probably will continue in blissful ignorance until, through either car shortage or labor shortage, they will be unable to get the amount of coal they require. It is worthy of note to remark that practically all bituminous operators firmly believe that this country is heading directly toward another and perhaps more serious coal shortage than before experienced. These operators formed their opinions on the fact that the mines will not have the labor to get out the coal, once the demand comes; furthermore, they believe the railroads will be unable to furnish an adequate number of cars to meet the demand which must come.

Reports continue to come in relative to railroad coal. A number of the larger operators and jobbers have taken railroad business below the old Government prices. This is rather disappointing, especially as we now understand that the railroads were unable to buy their steel rails any cheaper, even after they sent out bids all over the country. In short—the steel industry stuck together—an example the coal operators could well afford to follow.

CHICAGO

Steam and domestic demand brisk. Eastern coals in good request. Higher prices predicted.

Chicago has been having cooler weather, all spring, and this has helped the local situation to a considerable degree. The steam plant, as a result, has reduced its storage pile more than expected, and the householder has had to keep his furnace going steadily. In short, the local situation has been fairly brisk both among steam and domestic lines.

There has been an increase in business on Franklin County domestic coals, as operators in that field are advising the trade that the price on domestic sizes for June shipments will be $2.85 per ton f.o.b. mines, an increase of 10c. per ton over the May price.

Franklin County operators are not quoting prices calling for shipments after June 30, nor do they commit themselves as to what the July price on their coal will be.

The demand for eastern coal continues strong, and those that have good Pocahontas or New River coal from West Virginia and Hazard coal from Kentucky are having no difficulty in getting extra high prices on domestic sizes. Last reports show Pocahontas and New River lump selling at from $4.25 to $4.50 and Kentucky coal at $3.50. Indications point to higher prices in the near future.

Prices are as follows:

	F.o.b. Mines, Per Ton	Rate to Chicago
Southern Illinois		
Franklin, Saline and Williamson Counties, etc.		
Prepared sizes	$2.55 to $2.75	$1.55
Mine-run	2.35 to 2.50	1.55
Screenings	1.85 to 2.20	1.55
Central Illinois		
Springfield District		
Prepared sizes	2.55 to 2.75	1.32
Mine-run	2.00 to 2.35	1.32
Screenings	1.90 to 2.20	1.32
Northern Illinois		
Prepared sizes	3.25	1.24
Mine-run	3.00	1.24
Screenings	2.75	1.24
INDIANA		
Clifton Fourth Vein District		
Prepared sizes	$2.65 to $2.75	$1.27
Mine-run	2.35 to 2.45	1.27
Screenings	2.05 to 2.25	1.27
Knox County Field		
Prepared sizes	2.65 to 2.75	1.37
Mine-run	2.20 to 2.45	1.37
Screenings	1.90 to 2.25	1.37
New River and Pocahontas		
Prepared sizes	4.25 to 4.50	2.60

Mine-run	2.50 to 2.75	2.45
Cannel	2.75 to 3.00	2.45
Smithing coal	2.50 to 3.00	2.60

MILWAUKEE

Coal market quiet, with fair business. Pocahontas mine-run for steam purposes reduced 25c. per ton.

The Milwaukee coal market continues at an even tenor, with a fair amount of business. The first and only change thus far in the May schedule of prices was formulated during the week, Pocahontas mine-run for steam purposes being cut 25c. per ton, or from $7 to $6.75. There has been some newspaper agitation over the fact that the C. Reiss Coal Co., at Sheboygan, Wis., 25 miles north of Milwaukee, on Lake Michigan, advertises anthracite coal at lower figures than are current here, egg, stove and nut being 90c. less, pea 40c. and buckwheat $1.40. The lake freight to Sheboygan is the same as to Milwaukee. It is reported that coal is being sold at other ports to the north of Sheboygan at less than Milwaukee prices. Thus far there has been no explanation of the matter by those in control of the coal business here. The movement of coal by lake has slowed up a little. Receipts thus far since the opening of navigation aggregate 158,538 tons of hard coal and 466,711 tons of soft.

ST. LOUIS

St. Louis market has no demand for any kind of fuel and such little as is being forced on buyers is at a price below cost. The entire trade is utterly demoralized, both wholesale and retail, with the exception of the Carterville and Mt. Olive fields. Car supply good but movement a little slow.

The local situation continues unusually quiet with absolutely no demand at all unless it be for the normal requirements of screenings for the few steam plants that are in operation. The screening market in normal times would be stronger, but at the present time there is an unusual quietness in manufacturing, many of the large plants being on half time and some practically suspended.

The demand for steam coal in the country is insignificant. In the south the wet weather has prevented the lumber business from going forward as it should, and the rainy weather in the past few weeks has also retarded the wheat situation which usually calls for a light movement of coal for threshing for some districts as early as the middle of May.

The domestic situation locally could not be in any worse condition than it is at the present time. While the wholesale prices of high grade coal continue to increase, the local retailers are cutting prices and making it cheaper until they are delivering coal at less than it actually costs them. This pertains mostly to the wagon-load steam business.

The retail prices for the domestic user still continue to be pretty well maintained. One of the causes responsible for this is the action of the Standard operators who insist upon cutting prices to get the little tonnage available. Some of these mines are working one and two days a week on commercial coal. A few mines that are working on railroad coal get as many as four days a week. In other sections the mines are idle altogether and there is a growing dissatisfaction among the miners relative to the unequal manner in which the tonnage for the entire field is being distributed.

In the Mt. Olive field conditions still continue satisfactory on the two or three days a week that the mines are getting and prices are being pretty well maintained. In the Carterville field of Williamson and Franklin Counties there has been a noticeable improvement in the movement of the domestic grades of coal. As a matter of fact, screenings are also in good demand and are bringing the top prices. The railroad tonnage in this field is light at the present time, but in a general way the entire situation is satisfactory. Cars are plentiful, but the movement of cars on all lines from all fields in Illinois is just a trifle slow.

The condition in the Du Quoin field is not as satisfactory as that of the Carterville field, but there are some signs of improvement,

The anthracite situation in St. Louis is slow. The shipments are three to four weeks behind, but the local demand is not what it was expected to be. Orders were taken for about fifty cars of West Virginia smokeless coal to be shipped in during the latter part of May and the early part of June. Perhaps a dozen or fifteen cars of Arkansas smokeless moved in, but there is little demand for the Arkansas coal, while the demand for West Virginia seems to be increasing.

Coke is taking slowly with the public, but at the present time the general storage of coal is light. The coming month will see a fairly good start made on the storage coal tonnage.

The prevailing prices, which will be increased 10c. a ton on the first of June by the Franklin County operators, is:

	Williamson and Franklin County Association:	Mt. Olive and Staunton	Standard
Lump, egg and nut	$2.75	.....	.....
Washed Nos. 1 and 2 nut	2.85	.....	.....
Independent:			
Lump, egg and nut	2.55	$2.55	.....
6-in lump	....	....	$2.00 up
Washed Nos. 1 and 2 nut	2.85	.....	.....
Mine-run	2.35	2.20	1.60@1.70
Screenings	2.20	2.05	1.35@1.50
3-in. lump	....	2.30	.....
2-in. lump	....	.....	1.75
2x6 egg	....	.....	1.75 up

Williamson-Franklin County rate to St. Louis is $1.07½; other rates $0.92½.

I. C. C. Decisions

No. 9517—Ohio Valley Coal Operators' Association vs. Illinois Central Railroad Co., Director General, et al. Submitted Mar. 6, 1919. Decided May 1, 1919.

Upon complaint attacking the rates on bituminous coal, in carloads, from mines in western Kentucky on the Illinois Central, Louisville & Nashville, and Kentucky Midland railroads, to points in Mississippi Valley and southwestern territories, Illinois, and various other northern and western states, Held:

1. The rates assailed are not shown to be unreasonable per se, nor are they shown to be unduly prejudicial except to the extent stated in the following paragraphs.

2. The rates from mines on the Illinois Central to points in Texas by way of Mississippi River crossings south of East St. Louis are unduly prejudicial to the extent that they exceed the rates contemporaneously maintained from mines on the Illinois Central in southern Illinois to the same points through the same river crossings.

3. The rates from mines on the Illinois Central and the Louisville & Nashville to East St. Louis and St. Louis, proper, are unduly prejudicial to the extent that they exceed by more than 57.5c. per ton the rates contemporaneously maintained from mines in the Illinois Central's inner group and the Louisville & Nashville's Belleville group, respectively, in southern Illinois to the same destinations.

4. The rates from mines on the Illinois Central and Louisville & Nashville to East St. Louis, as applied on traffic for beyond, are unduly prejudicial to the extent that they are not lower than the rates contemporaneously maintained from the same mines to East St. Louis, proper, by at least 12.5c. per ton.

5. The rates from mines on the Illinois Central to Chicago, to points in the northwest as defined in this report, and to points in Illinois north of and including Mattoon and Decatur, are unduly prejudicial to the extent that they exceed the rates contemporaneously maintained from mines on the Illinois Central in the southern Illinois group by more than 25c. per ton.

6. The rates from mines on the Louisville & Nashville to Chicago are unduly prejudicial to the extent that they exceed the rates contemporaneously maintained from mines on that road in the Eldorado group in southern Illinois to Chicago by more than 25c. per ton.

7. The rates from mines on the Kentucky Midland Railroad are unduly prejudicial to the extent that they exceed the rates contemporaneously maintained from mines on the Illinois Central in western Kentucky to the same destinations.

General Statistics

Shipments and Value of Anthracite in 1917 and 1918

The statistics of shipments and value of anthracite in 1918 as compiled by the Geological Survey from the final reports of the operators, are given in the following tables. Although shipments of anthracite decreased 1 per cent., the value at the mines increased 18 per cent. The average value at the mines of chestnut, for instance, increased from $4.45 per gross ton in 1917 to $5.12 in 1918; of pea size from $3.12 to $3.77.

COAL AGE

Volume 15 New York, June 5, 1919 Number 23

Open Production Costs

By R. Dawson Hall

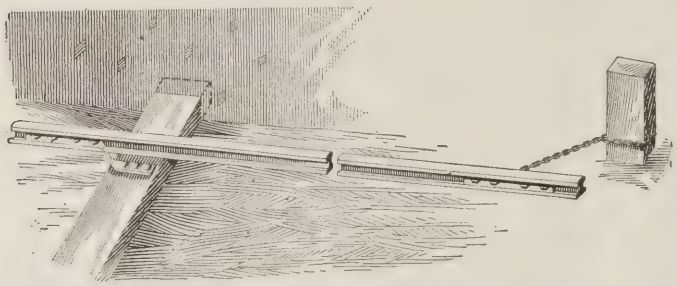
ALL signposts point to lessened secrecy in business. Years ago the seller kept his prices tucked with his watch in his vest pocket. Now he wears them both on his wrist and furnishes the public with the selling price of his product with as little hesitation as he announces the time of day. Yet in times past so secret were his prices, and so variant, he barely let his clerical force learn what they were. In those times even railroad traffic rates were matters of profound secrecy and private dicker.

Then came a period when a certain openness was affected as a concession to the public demand for an equality of treatment between consumers. But still the railroads had their rebates and merchants their private discount sheets. Consequently, actual prices were hard to determine.

Today, in marked contradistinction, railroad rates are uniform and easy of ascertainment. To have a friend in the railroad service helps not an iota in securing a transportation rate, nor is a box of cigars the magical means it used to be in the placing of cars. The railroads have open tariffs, open mine-rating, and some at least a published car supply; and now the coal business even has its open-price record. The buyer can now, in most cases, tell the exact price at which coal from any particular section is being sold in any given market.

Some industries have stepped further into the light. In their own interests many corporations, notably those producing copper, have decided to give their production costs in some detail. They have sought thereby to show how cheaply copper can be produced under the conditions with which they are favored and under the methods that they have adopted. Yet it has been interesting to note that despite the knowledge of the public that some copper was being produced at an extremely low figure, the price of copper all through the war was made uniform for all producers and was reasonably high. The public recognized that the low production cost was a tribute to efficiency and the outcome of business acumen, and hence was entitled to a reward. The copper business was left under self-regulation, whereas the coal industry, which has secret production costs and variant prices, was not allowed self-control and did not secure a uniform selling price.

It would be wrong to disguise the fact that the difference in treatment was probably due partly to the fact that coal is such a universal requirement that its low price is a matter for public clamor. It is not quite safe to argue from copper to coal, or from 1917 to 1925, or to assume that a product like coal, purchased largely by the small consumer and in such generous measure, will be viewed in the same way as is a product like raw copper, which is purchased mostly by the largest of corporations—by concerns, that is, which have from long experience a broader and more liberal point of view than the small consumer usually enjoys.



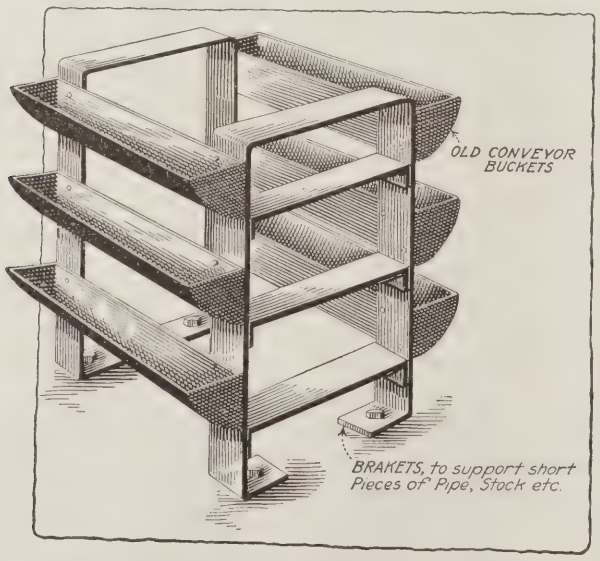
Dr. H. A. Garfield believes that the open publication of production costs is an assured way of averting public distrust and of allaying the growth of radicalism. Not a few corporation heads believe that he is right; others are equally convinced that such an open exhibit of the data of business would result in a public control as unfortunate to the consumers, the owners and their employees as has been the regulation of the railroad industry. COAL AGE would like to publish the views of its readers on this important problem. The time has come, if not for open production costs, at least for open expression of opinion on such matters of public interest.

IDEAS AND SUGGESTIONS

Preventing Track Rails from Creeping

BY RALPH W. MAYER
California, Penn.

Track rails on a slope or incline frequently have a tendency to creep downward or to buckle. A chain attached to one of the fishplate bolts, and fastened to a dead-man or anchored to a stump if on the surface, will hold the track in place. Another method is to weld an



HOW TO KEEP TRACK RAILS FROM CREEPING

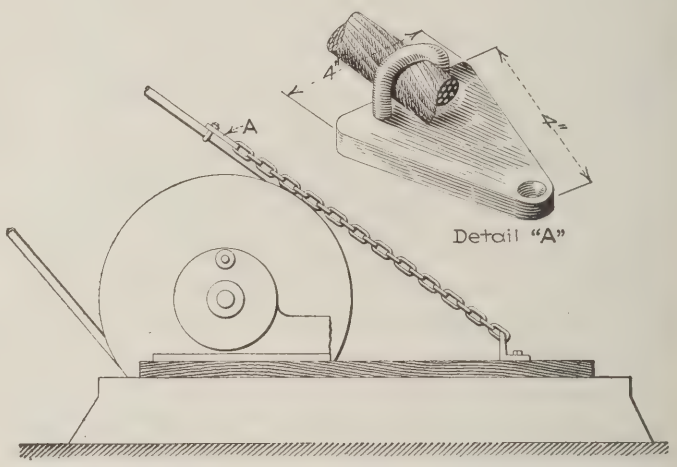
extension to the end of a fishplate, giving it a half twist and downward bend so that the welded extension will rest with its flat surface upon the tie (hitched into the rib) next above the fishplate. Holes are made in this piece, and it is firmly spiked to the tie.

Handy Catch-All

BY CHARLES H. WILLEY
Concord, N. H.

Instead of sending wornout coal-conveyor buckets to the scrap heap, and then disposing of them as junk, they can be utilized as catch-alls if made up as shown

DETAILS OF A PRACTICAL CATCH-ALL



in the illustration. A description of the manner in which this catch-all is made is hardly necessary. Odds and ends of flat bars such as are used for braces and stays were employed in the manner indicated

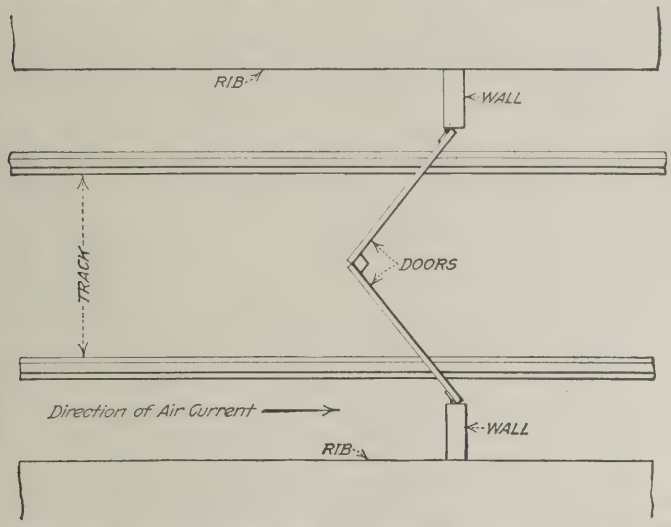
Method of Taking Up Slack Ropes

BY GEORGE BOWKER
West Frankfort, Ill.

The usual method of taking up slack ropes it to put something across the shaft, say two heavy rails, take off the rope, and cut away as much as is required; but in this method all the work is done at the end of the rope away from the drum. The process here described is accomplished by means of a chain having a piece of iron bent in the form of a knee, with a hole drilled in each leg. At the opposite end of the chain is another piece of iron made in the form of a triangle, having one hole in each apex (see Detail *A*).

When it is desired to take up the ropes the cager on the bottom is notified. He then places wooden blocks on the cage seats in the sump and notifies the engineer that all is ready. One of the nuts is then taken off one of the anchor bolts of the engine bed, and the end of the chain having the right angle iron attached is

DEVICE FOR TAKING UP SLACK IN ROPE



placed on the bolt and the nut screwed down. The other end of the chain is attached to the rope by means of a rope clamp. The clamp is attached to the rope, and before the nuts are put on the triangle plate is slipped on and secured. The rope is now fast and cannot move down the shaft.

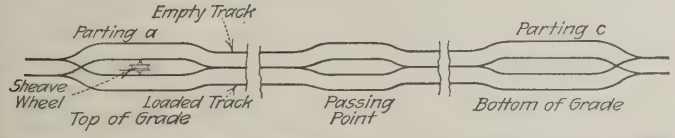
The engineer then gives the engines a little steam, raising the other cage into the dump; and as the down rope is fast, the movement of the drum causes the rope to slacken. The brakes are now set tight and the assistant goes inside the drum, takes off the clamps, and by means of a small pinchbar pulls the desired amount of slack rope through the hole, puts on the clamps again, and all is ready to resume operation.

The method just described is simple and expeditious. I have helped the engineer perform this "stunt" quite a few times, and together we have taken up the ropes and been ready to resume operations again within 15 minutes of the time we commenced to take up slack. The accompanying illustrations show the arrangement.

Mine Doors for High Air Velocities

It is difficult to open a door against a strong air current. A double door such as that shown below can be opened more readily than a single door. The tops of the doors in this case strike against the door frame next to the roof, while the bottoms are caught on cleats on

EASY TO OPEN THESE DOORS AGAINST AIR CURRENTS



the floor. When closed the two doors form a V-shaped figure, the door frame preventing them from closing any farther than shown. Being set at an angle with the air current, the doors do not have to be opened wide to relieve the air pressure.

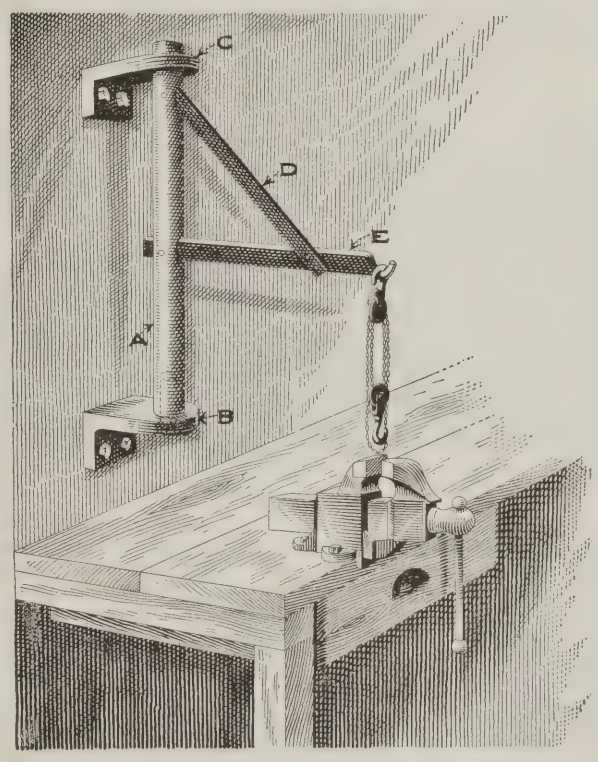
Wire Rope Assists Mule Haulage on Heavy Grades

By W. H. Luxton
Linton, Ind.

In the case of mule haulage in mines, unfavorable heavy grades against the load are hard on mules, are costly, and result in slow service. The following method of haulage saves mules and gains speed or time. Another advantage in the method proposed is that when mules become accustomed to such work and there is suitable means at both ends of the run, someone to unhook the mules, hitch them up again and start them out, then the driver can be discarded.

When the mules with the empties get to parting *C*, they can make the return trip to parting *A* with two cars, or trailers, as they are called. Three trailers are necessary, so that two be sent down from parting *A* to parting *C* with every empty trip while the remaining

ARRANGEMENT OF TRACKS TO FACILITATE HAULAGE



trailer is in use on the rope load. The passing point at the middle of the run is necessary to allow the empty trip and the mules to pass the rope load.

By referring to the accompanying diagram the arrangement of tracks will be understood readily. This system necessitates a double track or three-rail system most of the way; there should be a passing point for cars midway in the run in the event that a three-rail system is employed.

A light steel wire rope passes around the sheave wheel at parting *A*; when one end of the rope is at parting *A* the other end is at parting *C*. In practice, perhaps, the mule or mules can draw two loads on the grade in question, then hitch the rope to two loaded cars at parting *C*. In the meantime, hitch a mule or mules to four cars—two empty cars and two trailers—at parting *A*, also hitching the rope to the rear end of these empties. Now start the mules down the grade with the empty trip, at the same time hauling a trip of loads up the grade by means of the rope attached to the rear of the empties, passing around the sheave wheel and then to the front of the loads.

Wall Crane for the Bench

It is frequently necessary to lift a heavy piece of work from the floor to the work bench or vise, and if one cares to spend a few odd minutes to make a crane such as that shown below he can eliminate the heavy lifting. The device is simple to construct and is made from odd scrap stock of which plenty can be found about the shop. The upright *A* is made from a length

HOMEMADE CRANE FOR WORK BENCH

of old 2-in. pipe. The brackets *B* and *C* are made from pieces of flat strap stock. The top bracket simply has a large hole cut through it to take the upper end of the pipe, while the lower bracket has a piece of round stock set in it small enough to enter the inside of the pipe, as shown. This serves as a guide on which to swing the crane.

The diagonal brace and the horizontal arms *D* and *E* respectively are of bar stock. These pass through slots cut into the pipe and are pinned or riveted. A hook is formed on the end of the piece *E* to take a small tackle; this completes the apparatus. The device should be placed on the wall near the end of the bench so that it will serve the vise as shown and swing over the end of the bench to pick the work up from the floor.

Method Employed in Working the Crescent Mine

By Ralph W. Mayer
California, Penn.

SYNOPSIS — *In a mine producing a large tonnage of coal a considerable aggregate area is worked out daily. Under such conditions great care must be exercised to prevent bringing on a squeeze. This is here successfully accomplished through the use of both machine and pick mining.*

THE Crescent mine at California, Penn., is the largest operated by the Pittsburgh Coal Co. Its output is about 6000 tons per day. Surrounding it are some of the largest mines in the world. Underground operations on such an immense scale over an extended area bring problems of their own, such as are not encountered in minor operations. One of these is the prevention of squeeze, or creep. The Pittsburgh Coal Co. has adopted a new and novel method of working which has proved highly successful. It has been in use for several years and has passed the stage of experiment. "Half advance and half retreat" is the name given to it.

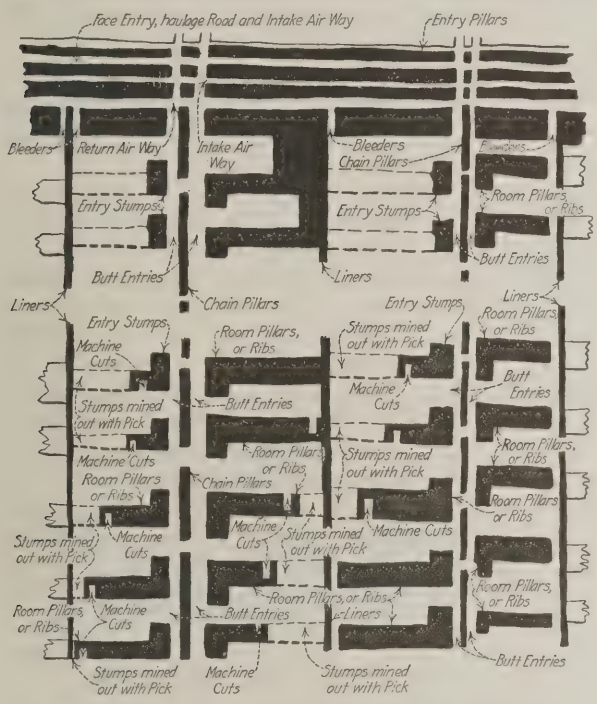
VIEWS OF THE TIPPLE AT THE CRESCENT MINE TAKEN FROM UP AND DOWN STREAM

The mine is worked on the five-entry system. The three middle entries are used as intake airways and the two side entries as returns. The middle of the five entries is used as the haulage road, it being an intake airway. These five entries are driven on the face of the coal and are called "face entries." The sets of face entries are driven 1500 ft. apart. The two side entries of the set of face entries have butt entries driven off them. The coal from both sides is pulled out through the middle face entry. The butt entries are driven on 550-ft. centers. The butts are driven 10 ft. wide, and a 50-ft. pillar is left between them.

Rooms are turned off both butts, 30 rooms on each one. The rooms on one butt are 250 ft. long and on the other 225 ft. long. The rooms from the right butt entry of one pair and the left butt entry of the adjoining pair are driven toward each other. A 5-ft. pillar is left between the face of the two rooms. The rooms do not break through into each other. A 6-ft. hole is kept in advance of the cut of the mining machine when the full length of the room has been nearly reached.

This 5-ft. pillar runs the full length of the butt entries. It is called a "liner," and helps to ventilate the old falls when the room pillars, or ribs, are drawn. Its size is so small that the roof will crush it, but it will still be air-tight and carry the air over the falls. As soon as the rooms are driven their full length, and up to the liner, a breakthrough, or crosscut, is made between adjoining rooms next to the liner. A breakthrough is also made through the face entry pillar into the adjoining room, next to the liner. These breakthroughs are called "bleeders," and allow the air to travel from the airway along the liner at the face of the room as well as pass from the butt entry up through the rooms. Efficient ventilation of all the falls in the room is thus provided.

The rooms are driven 24 ft. wide on 39-ft. centers and the pillars are 15 ft. wide. This gives 60 rooms to each pair of butt entries or 30 on a side. As the face entries are advanced the butts are driven off them 550 ft. apart. The pillars of the face entries are left of ample size, so that no trouble will occur from that source.



Rooms are turned off one of the butt entries as fast as it advances. No rooms are turned off the other butt entry of the pair until the butts are driven as far as they go. Then the rooms are turned from it at its inby, or face end, working back toward the face entry, or airway.

As fast as the rooms are driven to the liner the breakthrough is driven at their top, and the room pillar, or rib, drawn back. The rooms are advanced and the ribs drawn back so that the working faces of the different places make a diagonal line with the butt entry and the liner. This allows the roof to break better and no coal is lost. When the rooms of one butt are being worked the coal in the other is all in one solid block. After all the rooms have been started and most of the ribs drawn on the one butt, rooms are turned from the inby end of the other butt of the pair, and it is worked in the same manner as was the first butt. The entry stumps of the room pillars are left standing.

After the last room pillar of the first butt and several room pillars of the second have been drawn, the entry stumps are removed. The chain pillar is taken out at the same time. The second working follows immedi-

ately behind the first. The track that is used to drive the rooms is also employed to draw the pillars. The rooms are not allowed to stand idle, and there are no falls to clean up or timbering to do before work can be resumed. The roof falls behind the pillar drawing and takes the weight of the roof off the pillars, preventing them from being crushed into the floor. Two pairs of butt entries are usually placed on one air split, although this depends upon the number of men working on the butts. No timbering is used in the butt entries.

The rooms have two rows of props set in them. One row is set in the gob while the other is set close to the track. The props are set in pairs in this row, two props being set close together every 4 ft. Eight-foot props are used. The right side rib of the room is driven straight and the track is laid along it. This puts the straight rib and track on the outby side of the room of the first, or advancing, butt entry, and on the inby side of the room in the second, or retreating, butt entry.

METHOD OF UNDERGROUND OPERATION

This method allows the rib of the back adjoining room to be drawn without interfering with the next room ahead.

The rails of the room track are laid without ties. Channels are cut in the bottom coal left by the cutting machine and the rails laid in them. The rails are bolted together with fishplates. The 4-ton cars are hauled out of the rooms over these rails without difficulty. The motors do not enter the rooms but pull the cars therefrom by means of a reel and ½-in. cable. Armored chain cutting machines are employed. These are of the explosion-proof type and are operated by electric power.

These machines are used to undercut the coal in the room pillars, or ribs. A cut about 12 ft. wide is made into the side of the rib. This cut does not extend to the end of the rib, but 4 ft. of coal is left between the side of the cut and the end of the rib. This small stump, or pillar, is mined out by hand after several cuts by the machine have been loaded out and the rib has been broken through. A roof fall usually occurs as soon as the small stump has been removed.

A curved track is laid into the cut so that the car can be placed close to the coal. The pick miner employed in this robbing must be an experienced man, so that he will remove the car, take up the track before the roof falls, and not get hurt himself. A steel car is worth at least $150, and if a miner loses a few cars and some track he himself will be a losing proposition.

Only "pick" miners pull these small stumps, doing nothing else. They lose very few cars or rails. The "machine" miner loads the coal out of the cuts behind the machine, and a different price per ton is paid for the two kinds of mining. As soon as the pick miner has pulled the stump, the machine starts another cut, the same as the one before. A small 4-ft. stump is also left on the end of the rib to protect the machine loader and the cutting machine until the cut has broken through the rib. These small stumps are always removed by a pick miner before a new cut is started, so that there will be no small stumps in the gob to prevent the roof from breaking. All roof slate is gobbed on the side of the room which has been widened out opposite the straight rib when the room is driven. The accompanying illustration will help to make the method of working plain. The mine workings extend for about 7½ miles back from the tipple, which is located on the Monongahela River. Coal is shipped by rail and water.

The Pennsylvania R.R. running from Pittsburgh to West Virginia passes under the tipple. The main haulage road is driven through the coal bed from the tipple back to the end of the workings. The seam is on approximately the same level as the railroad track, and an incline is necessary to raise the track from the elevation of the seam to dumping height. The tipple extends from the point where the short incline emerges from the hillside across the railroad track, and out over the river. Two barges placed side by side can be loaded at the same time from this tipple.

Early Views Regarding the Coal Supply of Great Britain

The chief mineral industry of Great Britain at the present day—coal mining—was practiced in the north of England and south of Scotland in very early times, says Davide Bowen, in a recent issue of the *Colliery Guardian*. Doubtless this was the case also in all the other coal fields; originally, working was confined to the outcrops simply or for short distances from the surface. In a charter of the year 1234 there was an indication of the existence of the Northumberland coal supply; while the Yorkshire coal field is first mentioned early in the following century. The leasehold system with royalties appears to have been common in the 14th century.

On account of the fear felt that the supply of coal might rapidly be exhausted if intensive exploitation were permitted, it was a frequent practice of the lords of the soil to expressly limit the quantity of coal which might be worked per day. It was the prevalent opinion that coal could only be worked near the surface. In 1610 Sir George Selby informed Parliament that the coal supply of Newcastle would be exhausted in 21 years. This fear of exhaustion stimulated invention for draining and ventilating mines. It is interesting to note that, whereas in 1700 it was estimated that the total production amounted to only 2,612,000 tons, and to 10,080,000 tons in 1800, the tonnage for the United Kingdom in 1913 amounted to 287,411,869, valued at $708,758,708.

Preparation of Bituminous Coal—III

By Ernst Prochaska
Benton, Illinois

SYNOPSIS—*Shall the entire output of raw coal received at the washery be washed? Shall the coal be sized before or after washing? To what limit shall the washing be carried? These are some of the questions confronting the washery designer or manager, and they are answered in this article.*

THE coal discharged from the raw-coal elevator at the highest point of the washery must be separated from its impurities and screened into the different sizes demanded by consumers. The ways and means employed in this process vary according to the system of washing followed. As all the bituminous coals are similar in nature, it becomes necessary to study the different points involved before we can follow clearly the development of the different methods used.

The first question is: Shall the raw coal as a whole be subjected to washing or will it be better to screen out the fines? This main question can be divided into several parts, because different conditions require different solutions. The first sub-question is: Is it possible to improve the fines by washing? This can be answered in the negative with all possible assurance. The consideration, however, as to how fine the coal can be to be successfully washed is still disputable.

Results from Actual Operation

Laboratory investigations and results of actual operation give largely different limits. It can safely be stated, however, that coal passing through a 20-mesh screen will not show any marked improvement by washing. However, it is not possible to give an absolutely binding limit for all sorts of coal. A correct decision in regard to the permissible fineness of the coal to be washed can only be arrived at through accurate and reliable tests.

If it has been proved that the fines can not be improved by washing, the next question is: Is it possible to screen out the fines in the dry state? The condition of the coal in the mine will primarily determine this question. If it comes from a so-called dry mine, dry screening is probably possible, but if the coal comes out of a wet mine, or contains more than from 5 to 6 per cent. of moisture, all efforts at dry screening will fail.

The third question is: Are the advantages gained from the screening out of the fines sufficient to justify the cost of installation and operation of the necessary machinery? The considerations governing this point are as follows: (a) If coal is to be sized before washing, the screening operation will without doubt be more perfect. (b) Dust mixed with water becomes slime, which hinders the jigging process. If the dust has been eliminated, the jigs will deliver a refuse more nearly free from good coal and therefore work with greater efficiency. (c) If the impurities in the raw coal contain fireclay, which dissolves freely in the water, and on the other hand the coal dust is comparatively clean, the fireclay and the dust will be mixed together in the jigs and the resulting fines will be high in ash. The fines in this case will be of better quality if screened out before washing. (d) If the fines themselves contain fireclay, the wash water will become thick and difficult to clarify, requiring large and expensive clearing basins. (e) If the dust is sufficiently low in ash it can be mixed with the washed coal without increasing the ash in the final product. This method will also facilitate the difficult problem of dewatering the fines. (f) The possibility of reducing the ash in the washed product without increasing the loss of good coal, through screening out the dust, permits the addition of dust higher in ash than would be possible if the dust were not thus screened out.

In the light of the foregoing considerations, if heed is given to the fact that the removal of the fines is comparatively simple, the question of dust separation can be answered as follows: Except in cases where the raw coal contains too much moisture or where the nature of the material is such that little dust or sludge is produced, the installation of a dust separator ahead of the jigs is to be recommended.

The second question in regard to the proper method of washing is: Shall the coal be sized before or after washing? Close sizing before washing is not necessary. Only with a coal that is difficult to wash and one that is at the same time hard and not liable to make a great amount of fines, is sizing before washing to be preferred. Otherwise the sequence of operations will depend upon the nature of the coal—that is, how closely it should be sized or whether it should be washed unsized. Therefore, in washing plants we find at present the following main methods of procedure: (1) Sizing before washing, and the employment of separate jigs for each size. (2) Preparatory separation into two or three grades in addition to dust, and separate jigs for each of the three or four sizes. (3) Sizing into coarse and fine coal only, and separate jigs for both sizes. (4) Jigging of the unsized raw material with subsequent sizing into coarse and fine coal and rewashing of the fines. (5) Washing of the unsized raw coal without any sizing or rewashing.

With types 2 to 5, the final sizing of the coal for market is performed after washing. Type 5 is used for coking coals, and then only if the coal is easily washed.

Separation of Dust

Considering that not every washery is provided with a dust-collecting plant, and that the coal is sized either before or after washing, the required apparatus may be classified in the following order: Dust separating and collecting machinery, sizing machinery, washing machinery.

To separate the dust at once from the total raw coal would give only imperfect results. Therefore, it is desirable to screen the coal at first into two sizes besides the lump—a coarse product from ⅜ in. to 3 in., and a fine coal from ⅜ in. to dust.

A plant for the separation of dust should screen out in as perfect a manner as possible all the dust up to a previously determined size without carrying away particles of coarser coal; because, if part of the dust remains in the coarse coal, the intention of facilitating the jigging and avoiding cumbersome settling basins will not

have been fulfilled. On the other hand, if coarse coal goes with the dust some of the material which can be improved by jigging will not get the benefit of this improvement. Therefore, the fundamental principles are as follows: The utility of a plant for screening out the dust is in direct proportion to its perfect removal of dust containing no coarse coal.

Dust can be removed either on screens or by means of an air current. Screening appears theoretically preferable because the size of the perforations in the screen plates determines the largest size of particles that will pass through them. Failures encountered with the earlier installations were caused by the difficulty in keeping the perforations clear. This trouble, however, was overcome by the use of vibrating screens.

One great disadvantage of a screening plant for dust removal lies in the fact that such a plant is noisy, sub-

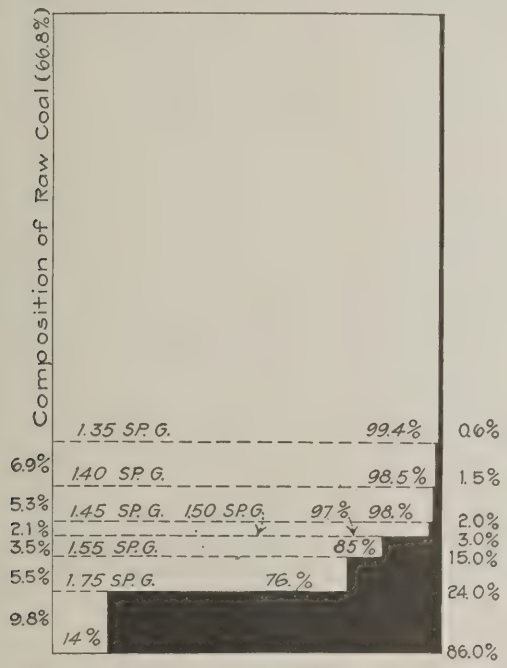


FIG. 1. CHART SHOWING COMPARATIVE EFFICIENCY OF DIFFERENT TYPES OF WASHERS

ject to frequent repairs, and that any air-tight inclosure for it is expensive and prevents the inspection of the moving parts. A dust separator using air currents works noiselessly and has no moving parts except the exhaust fan. It is also easy to inclose this type of apparatus in an air-tight casing, which is not objectionable because no moving parts requiring repairs are inclosed. With an air separator, however, it is not possible to get perfect separation in regard to sizes; some coarse material is always carried away with the dust or some dust remains in the coarse coal. In addition to a careful selection of the apparatus, its constant control and adjustment are required to insure satisfactory results.

What Shall Be Done with the Dust?

The use to which the dust should be put is determined by the nature of the coal, the amount of ash and the method of collecting the dust. With a coking coal, dust can be mixed with the washed fuel if the ash content will permit. This is the simplest method of dust disposal, because it helps in the dewatering of the washed coal. If the ash content is high, at least a portion can be mixed with the washed coal.

If the dust, however, is excessively high in ash it can be further treated in connection with the sludge, or it can be used as fuel under a boiler or in cement kilns, or it can be made into briquets. With fuel coal, the dust can be either briquetted or used under boilers; and if it is very high in impurities a considerable amount of it must be thrown away.

In the mining of coal foreign substances are mixed with the coal and carried with it through the washery. It is difficult to avoid this. Especially harmful are pieces of iron. They cause trouble and wrecks in the crushing plants, and work havoc with the conveyors and feeders. Furthermore, on account of their heavy weight they remain on the jig screens, where they form a heavy bed that prevents the required loosening up of the materials by weakening the water pulsation. This is detrimental to the effective operation of the jigs.

If a mine sends out a good deal of tramp iron, it is advisable to install a separate apparatus to catch all this foreign material. On account of the strong magnetic properties of iron a magnetic separator is the logical selection. Magnetic separators are simple and offer no difficulties. Any well-designed magnetic separator is adapted for this purpose, only it must be designed to handle great quantities. Magnetic separators are mainly of the revolving type and are either located in the bottom of a chute or in the head pulley of a belt conveyor. Revolving magnets have the advantage that they deliver the attracted iron automatically into a separate chute. Sometimes flat magnets are hung above the chutes, but in this case the attracted iron must be removed by hand.

The Jig Is the Heart of a Washery

The more or less successful selection or construction of a jig determines the economic success of a washery. The commercial results of a washery are influenced by the efficient yield of the jigging process. The yield of a washery is the proportion of the washed coal to the raw coal, or of the output to the input. A washery which produces 1200 tons of washed coal from 1500 tons of raw coal has a yield of $1200 \div 1500 \times 100 = 80$ per cent. This yield depends upon the ash content of the washed coal.

It is impossible to make an absolutely perfect separation of coal from refuse. Some refuse will be carried over with the washed product and a certain percentage of good coal goes into the refuse. This imperfection of jigging brings about a decrease in the yield which is in direct proportion to the reduction of ash. The possible yield with a predetermined amount of ash is influenced by the composition of the raw coal and can only be determined in each special case by a thorough investigation. If the possible limits have been determined consideration must be given to the selling price of washed coals having different percentages of ash. The yield, percentage of ash and the selling price must be considered together in order to arrive at the maximum total value of the washed coal.

A typical example will illustrate this. Let us assume that the possibility of putting a coal on the market commences at 8 per cent. of ash. The assumed price of coal with this ash content is taken at $3 per ton, and for each 1 per cent. decrease in ash the selling price advances 25c. per ton. Experiments gave the following results: An 8 per cent. ash gave 95 per cent. yield; a 6 per cent. a 90 per cent yield, and a 4 per cent. ash

gave an 85 per cent. yield. The price for the different coals will therefore be as follows:

$$8 \text{ per cent. ash coal} = \frac{95 \times 3.00}{100} = \$2.85$$

$$6 \text{ per cent. ash coal} = \frac{90 \times 3.25}{100} = \$2.925$$

$$4 \text{ per cent. ash coal} = \frac{85 \times 3.50}{100} = \$2.80$$

This shows that the best returns would be received by washing the coal down to 6 per cent. ash.

The results secured from the tests for the yield and percentage of ash can be used to calculate the composition of the different products if the amount and percentage of ash in the raw coal are known. If 3000 tons of raw coal with 10 per cent. ash are to be washed, we get the following results:

	Composition of Washed Product			Composition of Refuse		
	Combustible, Tons	Ash, Tons	Total Tons	Combustible, Tons	Ash, Tons	Total Tons
With 8 per cent. ash, 95 per cent. yield	2,622	228	2,850	78	72	150
With 6 per cent. ash, 90 per cent. yield	2,538	162	2,700	162	138	300
With 4 per cent. ash, 85 per cent. yield	2,448	102	2,550	252	198	450

The figures given in the table, even if exact conditions are not known, permit us to draw a conclusion in regard to the composition and nature of the raw coal. The raw coal is comparatively clean, containing only 10 per cent. ash. The impurities are mostly bone coal. This can be judged by the large percentage of good coal in the refuse, which can only be caused by a slight difference in the specific gravity between the coal and refuse.

The foregoing example is carried out for unsized coal. If sized coal is to be studied, determinations for each size must be made separately. In actual practice many other factors must be considered which, however, cannot be expressed in such a simple way by means of figures. The most important of such considerations are: (1) The possibility of using the refuse as boiler fuel or of recovering some good coal from it, by crushing and rewashing. The refuse shown in the example given could be easily used at the mine for boiler fuel. (2) As the cost of washing becomes greater with crushing and rewashing, this cost must be deducted from the price derived from the sale of the recovered refuse. (3) The possibility of making through close washing an especially clean and valuable coal that will be in demand even under adverse circumstances, may change the conditions mentioned considerably. This advantage can not be expressed in figures and should be especially considered by those mines that on account of the poor quality of their raw coal can not compete in the market with producers better situated.

The economic operation of a washery can only be based upon a complete and intelligently conducted washing test. The first step in such an investigation is to make a chemical survey of the mine. This consists in making careful sections of the coal bed in different portions of the mine, taking samples of the coal and impurities in the proportion in which they exist in the vein (so-called channel samples). These samples are taken down to the size to which the coal will be crushed at the washery. The samples are then mixed in equal proportion by weight, all fine material which passes through a 20-mesh screen is screened out for separate treatment, and the main sample is separated or classified by means of heavy solutions of varying specific gravity.

The objects sought by such procedure are, first, to obtain the theoretical ash or fixed ash in the pure coal, and second, to so classify the impurities as to plainly show the quantities, specific gravity and ash content of each class. For example, a coal which presents rather difficult washing problems shows the following results for the so-called sink-and-float test:

Pure coal lighter than	1.35 sp.g.,	69.7 per cent. with 7.11 per cent. ash
Impurities.....	1.35–1.40 sp.g.,	8.3 per cent. with 14.67 per cent. ash
Impurities.....	1.40–1.45 sp.g.,	3.6 per cent. with 19.10 per cent. ash
Impurities.....	1.45–1.50 sp.g.,	2.2 per cent. with 24.20 per cent. ash
Impurities.....	1.50–1.55 sp.g.,	1.0 per cent. with 28.02 per cent. ash
Impurities.....	1.55–1.75 sp.g.,	2.2 per cent. with 34.65 per cent. ash
Impurities.....	1.75 and over,	13.0 per cent. with 73.00 per cent. ash
Total raw coal.....		100.0 per cent. with 18.08 per cent. ash

From the foregoing it can be calculated that the ash in the washed coal would be 8.71 per cent. if the separation is made at 1:45 specific gravity and 9.10 per cent. if made at 1.55 specific gravity, assuming of course perfect washing. In the former case the washery loss would be 18.48 per cent. and in the latter 15.2 per cent., assuming that the refuse is free from coal.

A chemical survey of a mine, if properly conducted, will give accurate information on the following points: The amount and character of impurities in the run-of-mine coal; the amount of fixed ash or that in the pure coal; the amount of rejection which it will be necessary to make with a coal washer to produce any desired quality of washed product; the amount and character of impurities, if any, that could be drawn off as an intermediate product and used for boiler fuel, together with the heat value of such intermediate product; the composition of the washed product that may be expected; the size best adapted for the separation of the impurities; the units of machinery best adapted to produce the desired results with the least construction cost. In other words, such an investigation will show the financial returns that may be expected from a washery.

Mechanical Considerations

The mechanical arrangement of the jigs depends entirely upon the character of the coal. The specific gravities of the materials are to be primarily considered. The specific gravity of coal varies between 1.28 and 1.4, and that of the impurities usually lies between 1.5 and 3, or even higher in case of pyrites. If the specific gravity of the coal is close to or even overlaps in some instances the specific gravity of the impurities, we have a difficult problem on hand; but if there exists a considerable difference between the specific gravities of the two products the washing will become comparatively easy.

In the latter case simple pieces of apparatus are sufficient and one-compartment jigs can be used. In the first case, however, separate jigs with two or even three compartments must be employed and rewashing must be considered. Furthermore, it must be determined whether or not the impurities are diseminated throughout the coal. In this case the difference between the specific gravities of the materials is more or less obliterated and rewashing is advisable if the middle product cannot be used at the mine. If the difference between the specific gravities of the materials is small and at the same time the impurities are disseminated throughout the coal, jigging in three-compartment jigs would be advisable.

Many variations of the stated conditions exist, and it is difficult to predict which type of preparation should be used. The arrangement of the jigs should be such that the flow of the materials can be changed easily.

As to the actual performance of washers, it may be said in a general way that impurities lighter than 1.5 specific gravity are rarely separated by them to any considerable extent, and that a plant can be so designed as to eliminate practically all impurities heavier than 1.75 specific gravity and make a rejection of the larger portion of material between 1.5 and 1.75 specific gravity. There are few washers in operation, however, at the present time that are doing so well. Also, if the coal is not too fine there should not be more than 5 per cent. of coal in the refuse; and this amount will usually be less than 1 per cent. of the raw coal.

To show the efficiency of a washer, David Hancock, consulting engineer, has devised a chart upon which can be shown, graphically, the composition of the raw coal, washed coal and refuse. These are plotted to scale and show at a glance the comparative efficiency of different washers as determined from actual tests. A specimen of such a chart is shown. It represents the working of a Stewart type of washer. (See Fig. 1.)

Determining Composition of Raw Coal

It is necessary to know first the composition of the raw coal. This is determined by separations made for each five points of specific gravity upon an average sample. On the left side of the diagram to any convenient scale are laid off the percentages found. For instance, in this case the sample contained 66.8 per cent. of coal lighter than 1.35 specific gravity; therefore, at the distance represented by this figure the dotted horizontal line is drawn and marked 1.35 specific gravity. Also, the first class of impurity separated between 1.35 and 1.4 specific gravity was found to be 6.9 per cent. of the entire sample, and this distance is laid off to the same scale and marked on the chart.

After laying off the vertical scale in the same manner for the entire 100 per cent. of raw coal, the horizontal scale is then subdivided according to the per cent. of each class of impurity found in the washed coal as compared with the amount found in the raw coal. The balance, represented by the black area, is the rejection or refuse; both the quality and amount are indicated graphically, the areas being proportional to the weights of washed coal and refuse.

How to Use the "Efficiency Chart"

The figures to the right of the diagram show the amount of each class of impurity which goes to waste and the amount which is retained in the washed coal. For instance, it shows that 0.6 per cent. of good coal is wasted. It shows, further, that practically no separation of coal and impurities is made below 1.5 specific gravity, and that of the impurities heavier than 1.75 specific gravity 14 per cent. is retained in the washed coal and 86 per cent. rejected. It should be noted in this connection that heavy impurities when retained in the washed coal are usually fine material that would pass through a ¼-in. screen.

This chart can be called an "efficiency chart" of a coal washer and is applicable to any type of washer and any coal if the figures upon which it is based are accurately ascertained in any given case. In the case of the washer shown by the diagram, the ash of the raw coal was 15.94 per cent. and this was reduced by washing to 11.90 per cent., the coal being a difficult one to wash. The amount of refuse was 10.8 per cent. of the raw coal, and the yield was therefore 89.2 per cent.

The percentage of reduction of the impurities from raw to washed coal has been, and still is, frequently cited as a guide in comparing different washer efficiencies. It is certainly a very unreliable guide unless the washers which are compared are working upon the same coal. It will be evident to anyone upon a little reflection that the percentage of ash or sulphur reduction will depend more upon the nature and amount of the impurities in the coal than upon the different types of washers. I have before me figures showing an ash reduction from 21.50 per cent. in the raw coal to 4.50 per cent. in the washed coal, the work being done by a washer little, if any, better than the machine which made a reduction from 15.94 per cent. to 11.90 per cent., giving a reduction of 79 per cent. as against 25 per cent. The explanation is to be found in the difference in the amount and character of the impurities in the coal from the two mines and not in any essential difference in the washers.

Another result might be cited where a washer identical with the one which produced a reduction of ash from 15.94 per cent. to 11.90 per cent. showed the following results: Ash in raw coal, 21.4 per cent.; ash in washed coal, 3.08 per cent., or a reduction of 85.6 per cent. It is of course absurd to suppose that any such difference could have existed between washers of identical construction, but the difference is simply due to the fact that the two coals contain impurities quite different in character and amount.

The following maxims are therefore fully established: Practically no separation of coal and impurities can be made in material finer than 20 mesh. It is usually the part of wisdom to avoid pulverization of the coal as much as possible; but in this respect, also, each particular coal is a distinct problem.

(To be continued)

Coal Mining in Mexico

The Piedras Negras district ranks first in Mexico in the production of bituminous coal; in fact, it is the source of supply for the whole republic for railroad and smelting purposes. In the last years of the revolution the coal mines were greatly handicapped on account of confiscation, labor troubles, and the closing of the many smelters throughout the country which consumed their outputs; but the year 1918 saw the opening of many of the mines that had been closed down and a boom in the operation of those that had been running at half capacity. The Mexican Government has restored practically all of the mines to their former owners and the present State Government is doing its utmost to favor mines in the handling of labor questions.

The output of the coal mines in the Piedras Negras district is estimated to have reached 73,500 tons of coal a month, and if conditions continue to improve it will be increased to 100,000 tons a month. The making of coke on a larger scale is contemplated. At present there are two mines, the Mexican Coal and Coke Co. and the Cia. Combustibles de Agujita, that are equipped with coking ovens and are making a limited supply of coke.

Coal-Stripping Operations in Ohio

By S. B. Creamer
Cambridge, Ohio

SYNOPSIS — *Stripping operations in Ohio are characteristic of the field. The topography of the surface and occurrence of the seams largely limit this method of recovering coal to the outcrops. Great activity in stripping coal has been manifested in the last few years, and where operations have not been systematically carried out money has been wasted.*

THE open-pit (or stripping) method for the recovery of minerals on a large scale dates back many years. This system of mining was introduced in the iron-ore region of Minnesota in 1892. The term "stripping" is understood to mean the removal of all the overlying formation and the uncovering of the mineral for loading. However, it has been less than a decade since stripping operations made their advent in the coal fields of eastern and central Ohio on a commercial scale. But due to the incentive created by the demand for coal, stripping operations have increased so rapidly in the past three years that it has been impossible to get reasonable delivery on stripping machinery.

The great demand for coal and the prospects of a large return on the investment caused many companies to be organized, and much experimenting was done. As a result large sums of money have been wasted on poor property, worthless machinery and impossible or prohibitive layout.

While the general features of steam-shovel mining may appear simple, nevertheless good management, close attention to details and systematic work are essential to success. In the iron mines of Minnesota the overburden is loaded into side-dump cars which sometimes are transported a distance of two miles by dinkey. In the coal-stripping fields of Ohio the overburden is not loaded into cars as in the iron mines, but is simply cast to one side after the coal has been removed. Thus the depth of overburden possible to strip depends on the size of the shovel, thickness of coal, character of overburden and topography of the land. This feature is well brought out in Fig. 1, which illustrates a characteristic stripping operation in Ohio. The view is of the Coal Ridge Mining Co.'s No. 1 plant at Cambridge, Ohio. At the left is shown a large Marion shovel of the revolving type, which is removing the cover over the coal and depositing it on the right. The shovel in the foreground at the right loads the coal which has been stripped into cars, for transportation to the tipple. Conditions here lend themselves particularly to economical working and the operation is an ideal stripping. The maximum overburden is 40 ft. and the stripping follows the crop line on three sides of the property. The haulage track running through the stripping is a complete loop between the shovel and the tipple, making possible the moving of coal in either direction—an exceptional layout in the stripping field.

The first consideration of those contemplating a stripping operation should be a detailed study of the topographic and geologic structure as well as the thickness and steaming qualities of the coal. This study should consist of a topographic survey of the property. The property should also be thoroughly drilled to determine the thickness of the coal and the thickness and structure of the overburden. Core drills are most satisfactory for this work. Much stripping property in the No. 8 seam field has been hastily developed without the pre-

Fig. 2 shows the geological formation of the overburden of the No. 8 seam, while Fig. 3 shows that of the No. 7 seam

liminary surveys necessary for proper investigation and economic layout.

Ideal physical conditions are rarely found in the "stripping game" in Ohio. Such conditions would require a topography so that the property could be worked from two or more sides toward the center. The crop line of the coal should be such that the first cut of the stripping machine would be an open cut. This would necessitate a crop line with room for a spoil bank below the crop, the required width of which would be at least 150 ft. The geological formation of the overburden should include gravel or sand shale, which would make it possible for the shovel to dig without blasting. Under these conditions a bank of 40 ft. in depth could be moved without loss of coal with a 90-ft. boom for an indefinite number of cuts if properly operated.

In the No. 8 field the box (or through) cut is only used in a few instances, such as cutting through a saddle or low point in a hill. Without the box cut the crop line is an essential requirement, and this makes possible the open (or crop) cut for the first cut. Except in quite low flat ridges of small acreage the topography is such that the overburden increases rapidly in depth at each succeeding cut and geological structure more difficult to handle is encountered. Fig. 2 shows a typical geological section of the overburden overlying the No. 8 seam in Ohio. With one or two exceptions, this section prevails throughout the field. The coal is of little value until the 10-ft. cover line is reached, and the nature of the limestone is such that a cut 100 to 125 ft. wide can be dug without blasting.

In order to move overburden efficiently, and with a due regard for the proper care of the shovels, the overburden of succeeding cuts must be shot. The fireclay that lies directly over the coal is hard material, and it is almost impossible to dig it without shooting. However, it soon "air-slacks" on being exposed. Near the crop the limestone has a boulder-like formation caused by crevices due to ground water. In Ohio it seems to be impossible to do effective blasting without the aid of the jackhamer to drill the larger stones. The writer has measured stones 50 ft. long, 5 ft. thick and 10 ft. deep that have been moved a distance of 5 ft. horizontally from the face of the cut, without breaking, by a charge of 25 kegs of black powder placed 25 ft. from the face of the cut. However, as advance is made into the hill by succeeding cuts, the limestone takes the formation of a solid ledge and can be more economically blasted.

With the increase of overburden the cost of production increases, and to one not familiar with the "stripping game" it might seem financially impossible to mine coal at a profit in this manner. However, one must consider that from 90 to 95 per cent. of the coal is recovered by stripping in comparison to 65 to 75 per cent. by deep mining. Under the efficient management of George D. Rowland, the Apex Coal Co., of Cleveland, Ohio, has profitably moved overburden 70 ft. deep, moving 14 cu.yd. of overburden per ton of coal.

In the No. 7 seam field the geological formation is of a different nature, as shown in Fig. 3. It is necessary to blast the overburden when cover of 25 ft. or more is stripped.

Oil from Cannel Coal

The committee appointed by the Institution of Petroleum Technologists in February, 1918, "to obtain evidence in respect of the quantity of cannel coal and allied minerals available in Great Britain as a source of motor spirit, fuel oil and other products, and to formulate a scheme for the utilization of such supplies," has issued its final report, states the London (England) *Chamber of Commerce Journal*, April, 1919. This report states that a company, known as the Midland Coal Products Co. (Ltd.), has been formed with a capital of $500,000 (the whole of which has been subscribed), to produce oil from bituminous material, to manufacture domestic and industrial fuel, to deal with the chemical and other byproducts obtained, and to establish retorting plant on a commercial scale in which various retorts and systems of retorting can be tested. A site for an experimental and research station has been acquired in the center of the Midland coal field, flanked by the Great Northern, Great Central and Midland railways and adjacent to three shafts which are now bringing up a true cannel, an inferior cannel, half-inch top hards, and a soft coking coal. It is the intention of the company to test material from any part of the world. It is not only intended to erect large works (for which purpose an extensive site has already been secured), but also to assist in the establishment of works and to coöperate to that end with colliery owners and others in any part of the world. The company is receiving no government assistance, nor is it in any way interested in any particular type of retort or process.

There can be no doubt, the report states, that the more economical use of best raw coal, inferior coal, slack, colliery waste and other bituminous material not at present brought to bank, or, if brought to bank, put on the pit heaps, is becoming more and more a matter of immediate importance to the country, and more particularly to those engaged in the production or utilization of byproducts and the generation and distribution of power on a large scale. The technical advisors and others associated with the committee have done an immense amount of work in studying different types of retorts and producers already constructed, and designs and plans for suggested improved methods.

Know Your Battery Better*

By J. H. Tracy
Philadelphia, Pennsylvania

SYNOPSIS—*Because the storage battery will stand abuse uncomplainingly some people appear to consider this a sufficient reason for abusing it. While it is well to observe many precautions in handling a battery, the two chief points to be cared for are: keep the battery cool and avoid gassing—that is, water decomposition through circulation of excessive charging current.*

IT IS an unfortunate fact that among battery users and even the electrical profession generally there is little really known about the performance and care of storage batteries. It is the purpose of this paper to explain in simple language the action of the lead storage battery and to recite the important points of the proper manner for caring for storage batteries in operation, and giving the reasons for such rules as are laid down by the manufacturers for the proper care of the battery, and in this connection to point out the penalties that must be paid if these instructions are not followed.

The reasons for these instructions are not generally appreciated, and, if understood, would be better remembered than mere rules. Some knowledge of the penalties following the breaking of these rules will also be of assistance.

A storage battery consists of one or more cells; each cell consists of positive and negative plates immersed in an electrolyte. The electrolyte of all lead storage batteries consists of a mixture of sulphuric acid and water in such proportion as to best meet the requirements of the service in which they are to be used. For the propulsion of locomotives, street trucks and the like, the electrolyte has a specific gravity, as shown by the hydrometer, of approximately 1.27 to 1.28.

The voltage of each cell is approximately 2 volts on open circuit, but is higher than this when the battery is being charged and lower while being discharged. The nominal voltage of a battery is therefore the number of cells multiplied by two.

How Current Is Produced

When a cell is being discharged the current is produced by the acid in the electrolyte combining with the active material of the plates. The active material of the positive plate is lead peroxide and that of the negative is metallic lead in a spongy form. When the acid combines with the active material, lead sulphate is formed in both the positive and negative plates. The sulphuric acid, which has been absorbed by the plates, has, of course, been withdrawn from the electrolyte, with the result that the specific gravity of the electrolyte is reduced, and for a full discharge this drop in gravity will be from 100 to 125 points; thus, if the gravity of the fully charged cell is 1.275, the gravity at the end of a full discharge will be between 1.175 and 1.150, depending on the type of cell and the amount of the discharge.

To recharge the battery, direct current must be passed through the cells in a direction opposite to that of the current during discharge. This reversed current will reverse the action which took place in these cells during discharge. It will therefore withdraw the acid from the active material in the plates and restore it to the electrolyte. Thus, during the charge the electrolyte gradually becomes stronger as the acid is withdrawn from the plate until no more sulphate remains in the active material. All the acid having been returned to the electrolyte, it will be of the same strength as before the discharge, and the same acid will be ready to use over again during the next discharge, and the active material of the plate again in condition to combine with this acid.

During discharge the action has simply been that of the active material of the plates combining with the acid of the electrolyte. The whole object of the charge is to again withdraw this acid from the active material and return it to the electrolyte. When all the acid has been withdrawn, the cells are fully charged.

Some Facts About Discharge of Batteries

Operating instructions for storage batteries as issued by the manufacturers usually say little about discharging. As a matter of fact, a battery may, without injury to the plates, be discharged at any rate of current that it will deliver. There has been a widespread opinion that high rates of discharge are detrimental to the life of a battery. I can find no justification for this opinion with modern storage batteries. The maximum permissible rate of discharge is usually limited by the size of wiring used or by the capacity of the motor or other apparatus to which it is connected, and not by the battery itself. Caution should be given, however, against overdischarging the battery. It has already been pointed out that the drop in specific gravity of electrolyte should not exceed 100 to 125 points. Some have perhaps noticed the action of sulphuric acid on copper wiring terminals of a battery, and that a comparatively large amount of copper sulphate is formed when only a small quantity of the metal is eaten away by the acid. In the same manner, when the acid combines with the lead in the active material, the resulting lead sulphate occupies more space than the active material from which it is formed. The active material of all battery plates is porous, and this expansion is accommodated by a reduction in the size of its pores. All battery plates are designed to accommodate a certain amount of this expansion of the active material during sulphation; and in batteries of the type under consideration, this is limited to the amount represented by a drop in gravity of from 100 to 125 points, as already mentioned. Further discharge, even if it can be obtained at a satisfactory voltage, results in an excessive expansion, which so closes the pores in the active material that it becomes increasingly difficult to properly recharge the battery after an excessive discharge, and unless a proper recharge is given, the battery is liable to deteriorate. For this reason the discharge of any battery should not be carried beyond the point given by the manufacturers, as indicated by a hydrometer or by an ampere-hour meter.

*Paper presented before Illinois Mining Institute, May 23, 1919.

The function of the ampere-hour meter is to show the state of charge of the battery at all times and, therefore, indicate directly when the battery is approaching its limit of discharge as well as when it is approaching a state of full charge. To do this, it must be connected in the battery circuit at all times.

Operating instructions as issued by the manufacturers devote much more space to charging than to discharging. A battery must, of course, be charged with direct current, and the current must be connected to the battery so that it will go through it in the proper direction. The positive pole of the charging source must be connected to the positive terminal of the battery.

While a battery is being charged, the amount of sulphate in the plates decreases, the ability of the plate to give up the acid becomes reduced; in other words, during the early part of a charge the plates can give up the acid at a rapid rate, as there is a large amount of sulphate available. Therefore, a battery that is considerably discharged can be charged at a high rate, but as the charge approaches completion, currents at high rate cannot be utilized, and if high rates are maintained, only a portion of the current is used to withdraw acid from the plates, and the balance of the current acts to decompose the water in the electrolyte into oxygen and hydrogen, which are given off in the form of gas. Gassing of the battery, therefore, shows at any time whether or not the charging rate is too high. It therefore follows that when the cells are gassing on charge the rate of charge should be reduced. This reduction saves the loss of current, which is shown by the gassing, and also this gassing in excess has a wearing effect on the battery, which will be discussed further a little later.

The hydrogen and oxygen given off from the battery, when unmixed with a large amount of air, form a combination that will explode violently if ignited by an open flame or an electric spark. The compartment should therefore be open while the battery is being charged, in order that these gases may become mixed with air. Do not bring exposed flame, match, candle, cigar and so forth near the battery when charging or shortly after. If the battery is to be charged in a closed room or underground in the mine, especial attention should be paid to the ventilation of the charging room.

Effect on Plates of Escaping Gas

It has already been pointed out that gassing represents a waste of charging current. It does more than this. The action of the bubbles of gas in escaping from the pores of the plates and in "boiling" to the top of the electrolyte have a tendency to wash the active material from the positive plate.

It is a well-known fact that batteries wear out. This wear shows itself to the eye principally in the positive plate, the active material of which softens with use, and were it not for this unavoidable fact, the life of batteries would be much longer than at present. As the active material of the plate softens with use, there is a tendency for the softened portion on the surface to fall to the bottom of the jar in the form of sediment. The action of the gas in escaping from the pores of the plate and the eddy currents stirred up in the electrolyte when the bubbles of gas rise to the surface hasten this shedding of material and, by just that much, shorten the life of the battery.

Excessive gassing should, therefore, be avoided if the best life of the battery is to be obtained. A small amount of gassing at low rates and for a short time, at the completion of a charge, is not objectionable, but violent gassing should be avoided.

The cell temperature should not exceed 110 deg. F. The effect of high temperature is primarily to shorten the life of the wood separators which are always installed between the positive and negative plates.

There is always a tendency for wood in contact with sulphuric acid to become carbonized. This tendency is much accelerated at temperatures in excess of 110 deg. F.; and if a battery is regularly operated at temperatures in excess of this amount, it will probably be necessary to renew separators in the entire battery prior to the battery itself having ended its useful life.

There are also present in any commercial storage battery some impurities in the materials used, which cause a slight action in the cell, even when it is not in active operation. At high temperatures, these internal losses are increased, as is evidenced by the fact that a battery placed in storage will not lose its charge over a period of, say, six months if kept in a cool place. If kept at a temperature around even 100 deg. F., it will lose much more of its charge in, say, three months. In operation, however, the principal effect of high temperature on a battery is its deteriorating effect on the separators.

High Temperatures Soften Sealing Compounds

If temperatures much in excess of 110 deg. F. exist, there will follow a softening of the sealing compound and a warping of covers of the cells, so that the sealing of the cells will lose its effectiveness and there will result a possible slopping of the electrolyte, which will lead to deterioration of the wood trays in which the cells are assembled.

With the foregoing limitations in mind, it is advisable to charge a battery at relatively low rates if local conditions permit. Of course, the lower the rate of charge the longer the time required to complete the charge. If 12 or 14 hours are available, the charging can be done at a low rate: approximately one ampere per plate per cell; that is, a 15-plate battery can receive all its charge at approximately 15 amp., if 12 or 14 hours are available for the charge. If this length of time is not available, the charging rate should be higher at the start of charge and then reduced to the rate mentioned before the battery begins to gas.

Where an ampere-hour meter is used, as is usually the case, the following general rule can be given: the charging rate in amperes must be less than the ampere-hours still out of the battery until the finishing rate is reached. In other words, the ampere-hour meter will always indicate a rate which should not be exceeded at that time. Of course, any rate less than that indicated by the ampere-hour meter will be satisfactory.

More complete charging instructions are given in the instruction books issued by the manufacturers, but these instructions all conform to the general principles which have just been laid down. The important points are: Avoid gassing and keep the cell temperature below 110 deg. F.

There has been considerable said about boosting storage batteries. Boosting consists of giving a battery a partial charge, usually at a high ampere rate and for a relatively short time. Boosting in no way differs from charging and, therefore, the same rules should be followed.

It is highly important to give the battery a weekly equalizing charge, which consists of a prolonged charge at a low rate, preferably about ½ amp. per plate per cell until the specific gravity of the electrolyte will show no further rise over a period of one hour. As has already been pointed out, the object of charging is to withdraw all acid from the plates. In practice, the regular daily charges are not always given long enough to completely accomplish this. In fact this is not necessary provided the acid is completely withdrawn once a week by giving an equalizing charge. If this is not done and some sulphate is allowed to remain in the plates for a considerable time, it will gradually increase and the pores of the plate will become clogged and the battery lose capacity and deteriorate in such a way that it becomes increasingly difficult to restore the battery to its normal condition. To carry the daily charge to the full extent would involve an unnecessary amount of charging and gassing, which is not desirable. An equalizing charge properly given once a week accomplishes the desired result with a minimum of attention and a minimum of battery wear.

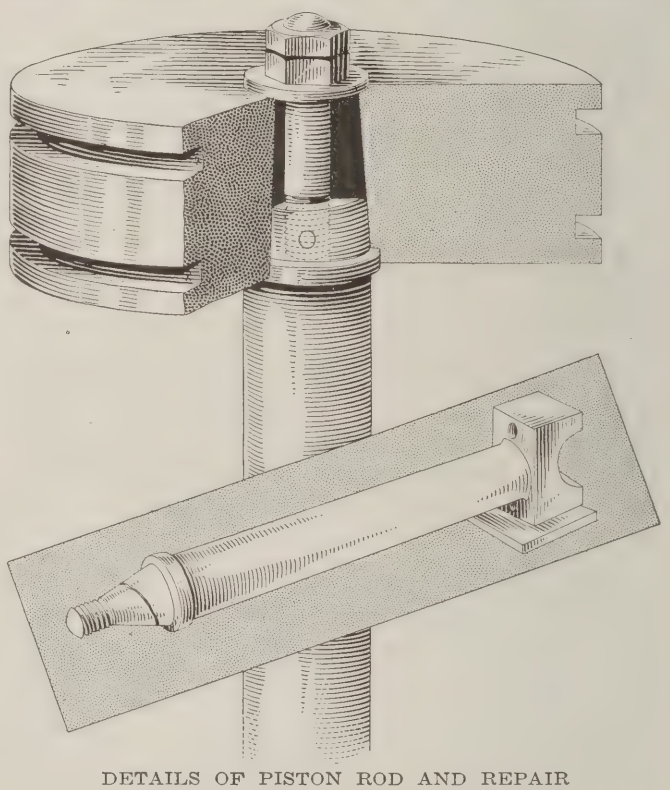
It is important that the plates of the battery be always covered with electrolyte. In order to accomplish this, it is necessary once a week, or possibly oftener, to add sufficient pure water to each cell to bring the electrolyte well above the tops of the plates. Use pure water for this purpose.

To determine whether natural water is sufficiently pure to use, a one-pint sample should be submitted to the battery manufacturer, who will make a chemical analysis of it, free of charge, and report to the user. If natural water is not sufficiently pure, it will be necessary to use distilled water, which can usually be purchased, or a small still may be installed by the user.

While the amount of impurities put into a cell at any one time may seem very small, these impurities accumulate with each filling, and will in time be present in such quantities as to affect the life of the cell.

The assembly of the cells is such that practically no water really evaporates, the bulk of the loss is due to disintegration of the water by the gassing at the end of the charge. No acid is lost in this manner, so none should be added to the cells unless some has been lost by spilling. Water should be added to the cells before charging in order that it may become thoroughly mixed with the electrolyte by such gassing as occurs. This is particularly necessary in freezing weather, as otherwise the water will remain unmixed and may freeze.

Keep the battery clean. Any piece of electrical apparatus should be kept clean and dry, in order that there may be no loss due to poor insulation. If the battery is not kept clean, the acid will slowly attack the wood trays in which the cells are assembled and not only weaken them, but may cause a failure of the insulation of the battery in such a way as to possibly cause burning of the jars, short circuits or a spark which may ignite gases around the battery and cause an explosion. Detailed instruction books give complete information as to how this can be most easily handled.



The battery should be inspected regularly and given such attention as may be required. Any piece of apparatus in daily use requires periodic inspections, followed by such cleaning and repairs as may be found necessary if the best results are to be obtained. Such inspections are less burdensome than the troubles which result with any piece of apparatus that is not properly cared for.

The action of the storage battery is relatively simple. The attention that it requires to keep it in regular daily service is simple and easily given. The mystery that exists in some people's minds regarding the battery is due to the fact that it does not complain under abuse. The operators do not appreciate, from their own observation, the results of abuse and so, in many cases, do not give the battery the attention that it deserves. It is hoped that this attempt to explain the reasons for giving the battery certain essential attention will result to the mutual advantage of both users and makers.

Emergency Piston-Rod Repair

How an emergency makeshift repair to an engine piston rod that had broken off at the tapered end, where it fitted into the piston, was made may be of interest to *Coal Age* readers. The design of the rod is shown in the illustration, which also shows the break as it occurred. The operating engineer had taken out the piston in order to examine and refit the piston rings. In putting the piston back and tightening up the nut, he broke the rod.

On looking the rod over it was found that a flaw and crack had existed, and when the rod nut was set up

DETAILS OF PISTON ROD AND REPAIR

tight the break resulted. The rod was of the type that had the crosshead forged on, and it became evident that to make or obtain a new one was a matter of weeks. Accordingly, a makeshift repair was necessary in order to operate the engine until a new part could be obtained.

The end of the broken rod was drilled and tapped out for a 1-in. stud; this was screwed in and pinned, the rod was placed in the piston, and babbitt metal was poured around the stud. The metal was peened down even at the top, a nut and large washer completing the repair. The rod worked satisfactorily by running the engine at half speed.

Heavy Paper Tamping Bags Prove of Service in the Blasting of Coal

Blasters as a rule realize the importance of tight tamping and of using proper tamping material. But proper tamping materials are not always available, so they sometimes use whatever may be near at hand with the result that more explosives are used than are necessary, increasing costs, or bringing down less coal or rock than could reasonably be expected from the quantity of explosives fired.

For instance, a miner will tamp with coal dust. This does not ordinarily pack well. Clay or loam would be much better, but a miner cannot be expected to go out of the mine for tamping whenever he loads a borehole. He therefore uses what he has at hand.

Miners and rock blasters are beginning to appreciate tamping bags made of heavy paper and used in many places as containers for sand, clay or loam to be used for tamping. The bags are particularly useful when loading holes pointed upward, the reason therefor being obvious.

A supply of these bags can be filled and taken into the mine or onto the job at the beginning of the day's work. The blaster is thus sure of having a tamping material that will give him maximum breakage at least cost. Their use also saves time when loading boreholes.

Tamping bags are useful when the blaster desires to make up charges of blasting powder in cartridge form as they usually do when loading uppers or holes in damp open work. They are much more convenient than clumsily made funnels or cones for which pieces of newspaper are generally employed.

Personnel of the Reorganized West Virginia Department of Mines

After the State of West Virginia, or at least the coal-producing sections of the state, had been redistricted in accordance with the terms of the Hale bill, it became necessary to appoint four new district mine inspectors. Following their appointment recently, both old and new members of the inspection staff lately were called to Charleston for a conference with the head of the department. The duties devolving upon each inspector were thoroughly explained by Chief Heatherman, who also pointed out the personal responsibility of each member of the force in enforcing the mining laws and seeing that conditions were safe.

During the day a photograph of the entire staff of the department was taken. This is reproduced here.

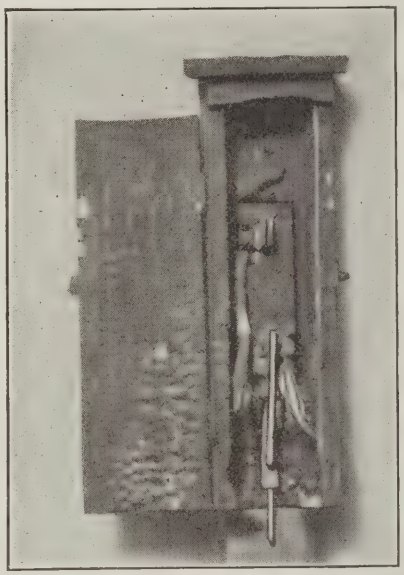
CHIEF OF THE WEST VIRGINIA DEPARTMENT OF MINES AND MEMBERS OF THE INSPECTION FORCE AT THEIR FIRST CONFERENCE SINCE REORGANIZATION OF DEPARTMENT

Reading from left to right, those in the photograph are: Eli J. Mason, Seventh District; James Golden, Fourth District; Edward Nicholson, Twelfth District; W. B. Riggleman, Fifth District; W. J. Heatherman, Chief of Department; Thomas Stockdale, Fifteenth District; R. M. Lambie, Thirteenth District; Zach Evans, Ninth District; E. L. Brewer, Eighth District; L. D. Vaughn, Eighteenth District; L. B. Holliday, Tenth District; M. B. Coulter, Sixth District; James W. Weir, Private Secretary to Governor; J. W. P. St. Clair, Seventeenth District; Evan L. Griffiths, Third District; J. L. Heizer, Chief Clerk; W. H. Sandridge, Second District; S. E. Hawkshaw, First District; V. E. Sullivan, Fourteenth District; H. L. Butler, Sixteenth District; R. L. Jenkins, Nineteenth District; J. G. Vaughan, Eleventh District.

Wiring at Mines

By Jack L. Ball
Amsterdam, Ohio

SYNOPSIS—*If maximum results are expected from an electric mine system, maximum care must be expended thereon. In many mines either through ignorance or haste electric wiring is installed in an extremely careless and haphazard manner. In order to obtain best results as well as secure a large measure of safety, the wiring of a mine should be installed with as much care as it is in a residence, factory or office building.*



ELECTRIC wiring both inside and outside the mine should receive a maximum of care and have the best workmanship bestowed upon it that it is possible to obtain. It is noticeable, however, that this important detail receives little attention in many instances. Wiring in some coal-mine power houses, if carefully examined by insurance inspectors, would be condemned as entailing too great a fire risk. Such wiring is in some instances improperly insulated, the circuit breakers are mounted on wooden panels, light and motor circuits are connected between the breaker and the generator and not protected with fuses, switches are placed in inaccessible positions with inflammable surroundings, connections are loose, and poor workmanship is the rule rather than the exception. The local mine management is responsible for allowing such an installation to exist.

Inside of some mines the condition of the trolley and machine wires is such that it is a wonder that power can be transmitted at all, that someone is not electrocuted and that the mine is not continually on fire. Loose trolley wire connections or splices, wire loose from clamps and sagging, hangers improperly spaced usually too far apart on straight road and too few in number on curves, hangers loose from their supports and poor bonding, are a few of the common faults encountered. Machine wire may frequently be found in all sorts of inaccessible places, under falls, in abandoned workings or under water, with no protection from short-circuits except the circuit breaker on the switchboard in the power house. Single switches are placed on the positive side and installed in inflammable boxes. The worst feature from the standpoint of efficiency is loose connections or joints, grounds, and the fact that the copper is not infrequently too small to carry the load intended.

Where coal is mined and hauled electrically, the transmission lines as a general rule should have more attention, both in installation and upkeep, than they usually receive. Trolley wire should be run at as nearly a uniform height as possible. This, of course, is governed by the height of the entries, timbering and the like. However, trolley wire can be placed at a predetermined distance from the side of the rail and kept uniform in this respect. Patent trolley-wire splices that are in general use give excellent service, but in some instances because of the vibration induced by the trolley wheel, the wire becomes loosened, and arcing and heating begins with a resultant loss of power.

A practical illustration that shows that heat means a resistance is this: It will be noticed in cold weather that the shunt field of a generator requires considerable resistance cut in to keep the voltage normal. In the summer time when the weather gets warm the generator heats up to such an extent that it is necessary, at times, by means of the shunt field rheostat, to cut out all resistance to get the normal voltage; and even then this somtimes falls several volts below the potential desired.

A mine foreman in southern Ohio complained that two gathering motors and one haulage motor were not receiving enough power to handle the usual number of cars. A test was made at night, at which time several coal-cutting machines were using power. "Jumpers" were used from the trolley wire and rails to the machine circuit, which had been cut off from the regular source of supply. Two splices were found to be very hot and required renewing while three were quite warm.

RESULT OF PLACING A SWITCH IN A WOODEN BOX

After tightening the setscrews of the three splices and rebonding four rail joints, the trouble was overcome.

Trolley wires are either suspended from the rib, the roof or the top; the hangers are fastened in the coal, roof or wooden timbering with some from of expansion bolt or lag screw, or are clamped to "I" beams with some variety of clamp or bolt hanger. When using the expansion bolts care should be exercised as to the size of the hole drilled. If the diameter is too large, the bolt will soon work loose. If a clamp or a bolt type of hanger is used it is advisable to see to it that they are made tight when installed and that they are kept in this condition. If maximum efficiency is expected from a mine haulage system it should receive commensurate care.

Machine wires are sometimes much abused. In some cases it is found that they are strung around in all sorts of haphazard ways, with little attention paid to insulation or upkeep.

Copper forms an important item of mine expense. Circuits should be as short and direct as possible to get the desired results. If an efficient system is wanted,

with the fire hazard eliminated, the same care should be exercised in hanging machine wire that is used in an office or factory building. It is found sometimes that it would be better to use a smaller and a greater number of insulators. Wires should be well insulated, of course, not merely hung up on large-size insulators just to keep them off the bottom.

Care should be used when making joints. What is known as the "Western Union" joint, soldered, makes an excellent connection. As solder has a higher resistance than copper, it is advisable to first thoroughly scrape the wire, which insures a copper contact; after the joint is made it can then be soldered. Splices of the sleeve type are much in use and give excellent service. When using them, however, the proper size only should be employed and the wires butted together and the set-screws set up tight. Too large a splice with the extra space filled in with anything that is handy should never be used if a good joint is desired. Such work should be neatly done, with permanency in mind.

To save wire in many instances shortcuts are taken through some abandoned part of the mine. No careful workmanship is attempted. Falls occur, the wire is covered with slate and rock, or is immersed in water, and the machine runners are without sufficient power to operate their machines. Eventually, the wire is so completely covered up that it can never be recovered and is a dead loss.

Wire should be completely insulated from wooden timbering. It sometimes happens that a short-circuit occurs, heating the wires sufficiently to ignite the timbers. A small blaze in an aircourse soon reaches such proportions that it may result in a disastrous fire.

Usually, the machine circuits are not protected with circuit-breakers or fuses inside the mine. It is found, however, that single-pole switches, connected on the positive side, mounted on a slate base, the whole being placed in an unprotected, inflammable wooden box, are much in use. When machine and trolley wires are in the same entries, as many are, a two-pole switch should be used. Then, if for any reason a "short" occurs between the trolley wire and the negative side of the machine wire, the circuit can be completely broken and haulage can be resumed with a minimum loss of time. Also, if both the positive and negative sides are open, this insures a guarantee of safety when making repairs.

The accompanying illustration shows the result of a short on a machine circuit. The single-pole switch was mounted on a slate base, the whole being inclosed in a soft-pine box. No tubing was used for the outlets and the inside of the box was not protected with asbestos sheeting or other noninflammable material.

ALL MINERS AND SHIPPERS of coal are interested in the manner in which fuel is sampled by consumers. It should be done preferably when the coal is being unloaded, and in a regular and systematic manner, so that the entire quantity of the coal sample will be a fair representative of the shipment. Samples taken from the surface of coal in piles or bins, or in cars and barges, are generally unreliable. A shovel is often used for taking equal portions to make up a gross sample. For run-of-mine or lump coal, the gross sample should not be less than 1000 lb. If the coal contains an unusual amount of impurities in pieces of considerable size, the gross sample should be about 1500 lb., according to the Bureau of Mines. For slack coal and small sizes of anthracite in which the impurities are not in abnormal quantities, or are not in pieces larger than ¾ in., a gross sample of approximately 500 lb. is sufficient.

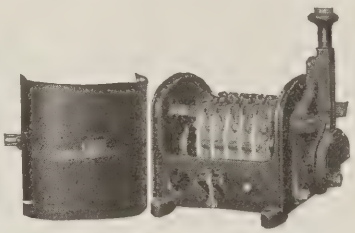
Legal Department

MULE AS AN "APPLIANCE"—A mule used in mining operations is an "appliance" within the provisions of the Indiana Employers' Liability Act, which requires employers to provide reasonably safe appliances, etc., for use of their employees. (Indiana Appellate Court, Van Hentenryck vs. Jackson Hill Coal and Coke Co., 120 Northeastern Reporter, 664.)

POWERS OF COAL-MINING COMPANY MANAGERS—The general manager of a corporation operating coal mines on leased property has no implied authority to sell or dispose of to another any part of the leasehold estate. (West Virginia Supreme Court of Appeals, Carroll-Cross Coal Co. vs. Abrams Creek Coal and Coke Co., 98 Southeastern Reporter, 148.)

INJURIES IN KENTUCKY MINES—A mine mule driver was not necessarily guilty of contributory negligence, barring recovery for injuries sustained in collision with a mule driven by another driver because he failed to stop on reaching an air curtain, raise it, and look beyond, where he had never been instructed by the mine boss to do so. Operators of different trips of cars are not fellow servants of each other within the rule of law applicable to Kentucky mines that an employer is not liable for injury to an employee when caused by negligence of a fellow servant. (Kentucky Court of Appeals, Tyree vs. R. C. Tway Mining Co., 208 Southwestern Reporter, 817.)

SHIPPER'S LIABILITY FOR FREIGHT CHARGES—The shipper of a carload of coal is primarily liable, as against the carrying railway company, for all proper freight charges involved. This liability of the shipper in interstate commerce cannot be specially released by a railway company as that would involve an unjust discrimination against other shippers. Under the Interstate Commerce Act, a railway company is not bound to notify the shipper of insolvency of a consignee and nonpayment of freight charges collectable from the latter, as a basis for holding the shipper liable. (Illinois Supreme Court, New York Central Railway Co. vs. Philadelphia & Reading Coal and Iron Co., 121 Northeastern Reporter, 581.)



WORKMEN'S COMPENSATION ACTS APPLIED—Where a coal company's employee was struck by an automobile in a street while mounting his wagon, after having returned from a saloon where he went to telephone to the company's office that certain unloading equipment had been left off his wagon, was injured in an accident "arising out of and in the course of his employment," within the meaning of the Indiana Workmen's Compensation Act, entitling him to an award under that act. (Indiana Appellate Court, Ceislik vs. Consumers' Co., 121 Northeastern Reporter, 832.) And a coal hauler who died of heat stroke while shoveling coal on a very hot day must be deemed to have been injured as such result of his employment as to entitle his dependent relatives to an allowance under the Connecticut Compensation Act. (Cunningham vs. Donovan, 105 Atlantic Reporter, 622.)

DUTY TO MAINTAIN SAFE APPLIANCES FOR MINE EMPLOYEES—Supporting plaintiff's right to recover damages for injuries sustained because of defects in a mine car on which he was riding, the West Virginia Supreme Court of Appeals decided in the recent case of Long vs. Pocahontas Consolidated Collieries Co., 98 Southeastern Reporter, 289, that an employer is bound to use reasonable care to provide his workers with reasonably safe machinery and implements with which to discharge their duties. Unless the defect occurs in the use of the particular instrumentality by the employee and is slight and easily remedied by the employee, the employer will be liable for injuries sustained because of the defect, unless it clearly appears that the defect was open and apparent and that the servant, by the reasonable use of his faculties, should have discovered the defect in time to have avoided the accident.

New Apparatus and Equipment

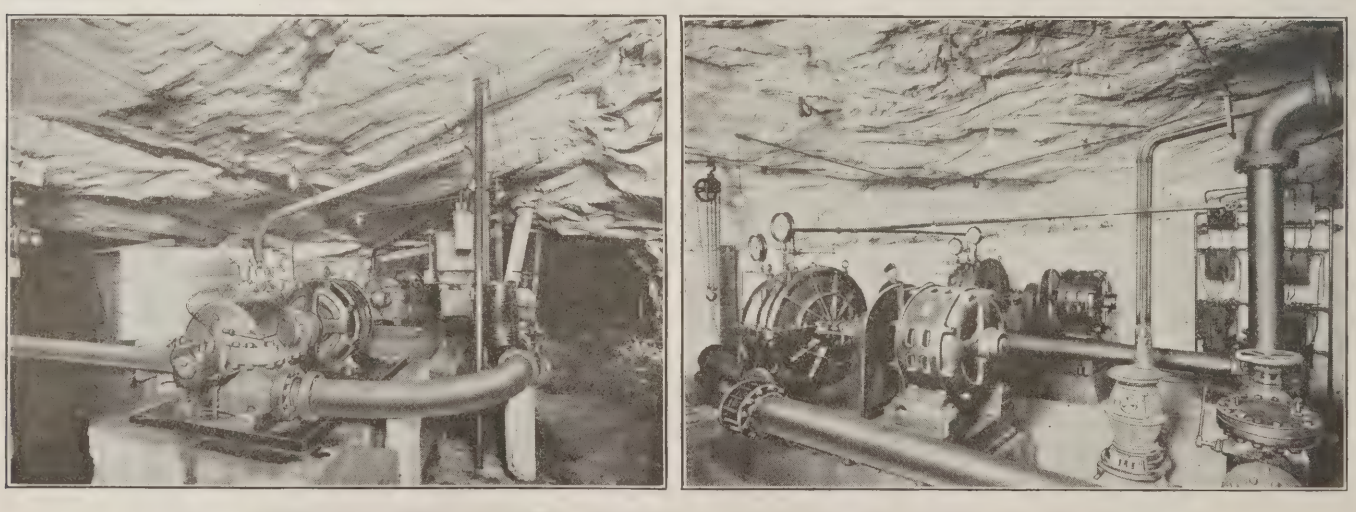
Master Controller for Use with Automatic Magnetically Operated Controllers

The accompanying illustration shows a new multi-speed full reverse master controller for use with automatic magnetically operated controllers. This master is smaller than previous designs and is especially applicable to machines where the operator's attention should not be diverted from the work or machine, and where space is limited. An internal gear drive, which is entirely inclosed but which is readily accessible by the removal of four screws, eliminates the liability of accident to operators through the catching of fingers or clothing in the bevel gears usually employed in straight line drive controllers.

THE NEW CONTROLLER

This master controller may be mounted horizontally or vertically, the former permitting straight line movement of the handle and the latter a radial movement. A centering latch operated by a button in the handle indicates to the touch the "off" position of the master, while a strong notching spring is used to indicate the five positions in either direction. A maximum of 12 fingers may be mounted on the finger board, using six in each direction of rotation.

The new controller, although small and compact, is so designed that by the removal of two bolts the entire finger board may be taken from the frame, while the removal of three bolts allows the entire shaft and contact fingers to be withdrawn. Inspection, renewals and repairs are therefore easily effected. The construction of the finger board and drum follows the Cutler-Hammer standard, in that the fingers and segments are clamped to square insulated steel shafts, and adjacent contact points are separated from each other by arc barriers. This master controller is a new development of the engineering department of the Cutler-Hammer Manufacturing Co. of Milwaukee.



Economical Electrical Equipment for Mine Pump Service

The most essential requirements of mine-pump motors are that they run continuously and take as little power as possible. These needs are met by a complete line of Westinghouse motors and control built for all sizes and commercial circuits, either alternating or direct current. In addition to these the advantage of low first cost and maintenance expense, great compactness, flexibility and ease of control inherent with electric drive are obtained.

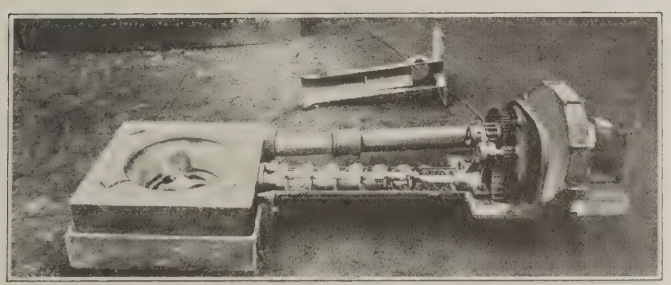
The simplicity and ruggedness of the type CS squirrel-cage motor especially adapts it to mine-pump service. It is built largely of steel and has nothing to wear except the bearings, which are large, well lubricated, and require but little attention. These motors may be started at the motor or at a distance. When started at the motor those smaller than 7½ hp. use a simple fused knife switch, while the larger ones require hand-operated auto-starters. When started from a distance an automatic starter is employed, of the resistor or auto-transformer type. This gives thorough protection and operates at high efficiency at both speeds. Only a simple double-throw switch is required to change from one speed to the other.

If the power source is limited, or a speed reduction is at times desired, the wound-rotor type CW motor with the same general mechanical characteristics as the type CS motor is furnished. With this motor also either hand-operated control at the motor or automatic control at a distance may be used.

Many mines have only direct current available, and for these type SK motors having the same simple,

TYPICAL UNDERGROUND ELECTRICALLY OPERATED PUMP STATIONS

strong and reliable construction, steel frame and rugged bearings are used. These motors are built self-starting as large as 20 hp., so that they may be thrown directly on the line from any desired point. For pumping from a sump, a float switch in connection with an automatic controller will start and stop the motor at the desired limits.



An especially handy outfit and an efficient arrangement of pumping equipment is obtained by mounting a motor-driven pump on a truck or mine car. This will enable quick transportation of the pump to any necessary location.

Westinghouse motors for mine pumps of either alternating or direct-current type are mechanically and electrically designed so as to give continuous, dependable and efficient service with little attention over long periods of constant operation. Where necessary additional protection may be added by inclosing the motors or supplying especially treated insulation to protect them from grit or dampness.

Small Electrically Driven Automatic Underfeed Stoker

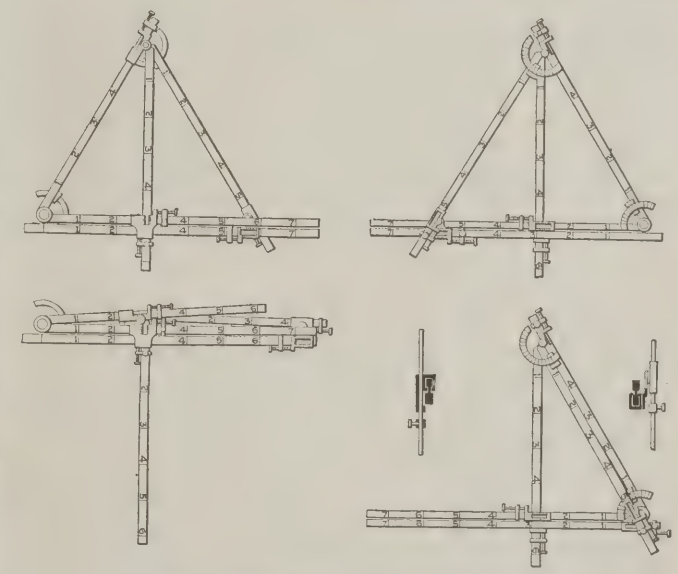
The utility and scientific correctness of feeding bituminous coal to a fire from below is well recognized. The convenience and efficiency of the automatic stoker are also well known. Heretofore apparatus for mechanically stoking boiler or other furnaces has been built only in comparatively large units. These were far and away above the requirements of the small apartment house or large residence.

The American Smokeless Burner Co., of Seattle, Wash., has developed a type of automatic underfeed

SMALL AUTOMATIC UNDERFEED STOKER

stoker that may be constructed in small sizes. This device, which is electrically driven and automatic in operation, is made in five sizes giving a range in fuel feeding of from 2 to 800 lb. of coal per hour. It will thus be seen that the smaller sizes of this machine might be used for house or apartment heating.

The accompanying illustration shows one of these stokers set up in the open and the cover removed from some of the machinery. Coal is fed from a hopper or bin to the screw conveyor that forces it into the firepot at its extremity. Here blast is supplied by a fan and a revolving agitator in the center of the firepot forces the coal upward and breaks up any mass of coke that may tend to form. A single motor drives both fan and stoker proper.



With a device of this kind feeding coal from below and supplying draft under pressure at the proper height, also with the fuel sufficiently agitated to prevent the formation of a bed of coke, combustion cannot well be other than perfect, or nearly so, and smokeless chimneys from furnaces where these stokers have been employed have been under observation for long periods and failed to show smoke except when the operation of the stoker has been interfered with. Furthermore, combustion is complete.

This stoker, of course, may be used for steam power generation but possibly lends itself quite as readily to hot water and steam heating plants where heretofore hand firing has been all but universal. In it several different kinds and sizes of coal have been successfully burned smokelessly. Any coal to be handled by it must be crushed to suitable size to pass readily through the conveyor. It is therefore particularly adapted to slack and nut—ordinarily not used for domestic purposes.

Trigonometer Solves Mathematical Problems Without Computations

The accompanying illustration shows a mathematical instrument known as a "trigonometer," designed to solve various mathematical problems without computations. It is particularly useful to the surveyor, or to others frequently confronted with the solution of triangles or the making of other trigonometric computations.

As may be seen, the instrument consists of four graduated bars joined together by one fixed and one movable

FOUR VIEWS OF THE TRIGONOMETER

protractor, one right angle slide and one varying angle slide. Thus the three sides, the three interior angles and the altitude of any triangle may be quickly found if sufficient data are available to solve the triangle mathematically. Suppose, for instance, the length of two sides and the included angle are known. The angle may be set on the fixed protractor while the length of the two sides may be scaled off on the bars joined by this protractor. The third bar then represents both in length and direction the third side of the triangle in question, while the fourth bar gives its altitude. In a similar manner the triangle may be solved if the magnitude of one side and two angles are known.

This instrument is the invention of Edward L. Renstrom, of Carbondale, Colo., and is covered by U. S. Patents, Nos. 1,149,085 and 1,268,620.

Coal-Mine Accidents by Nationality

The following table is published by the United States Bureau of Mines in its January Statement of Coal-Mine Fatalities in the United States. The remarks of the bureau regarding the table cannot be bettered and so are here reproduced:

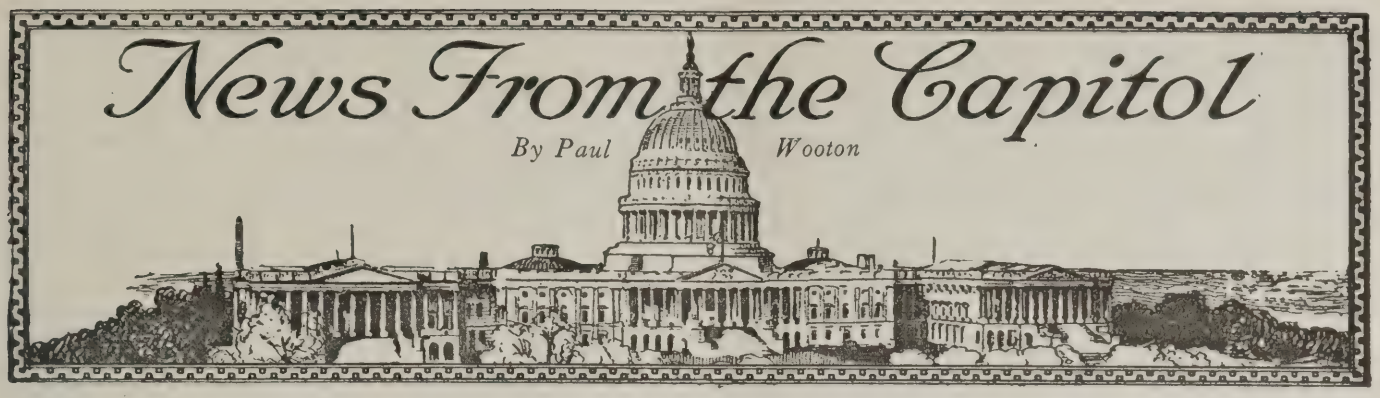
(a) Based upon official records for the years 1915 and 1916 as reported by the state departments of mines. (b) Not segregated, as only a few are employed.

Coal Production in Canada in 1918



The preliminary report of John McLeish, chief of the Canadian Division of Mineral Resources and Statistics, of mineral production during 1918 gives the total production of marketable coal at 14,979,213 short tons, valued at $55,752,671, or an average of $3.72 per ton, being the largest on record with the exception of that of the year 1913. The production in 1917 was 14,046,759 tons, valued at $43,199,831. The total output including waste and unmarketable slack in 1918 was 15,405,958 tons, as against 14,435,361 tons in 1917. The production of 1918 included 115,405 tons of anthracite, all from one mine in Alberta; 11,532,592 tons of bituminous and 2,784,283 tons of lignite coal.

The increase in production has been obtained chiefly in Alberta, though there were also substantial increases in British Columbia and New Brunswick. The Nova Scotia production fell off 474,289 tons, or 7.5 per cent. as compared with 1917—New Brunswick increased by 78,651 tons, or 41.6 per cent.; Saskatchewan fell off 10,135 tons, or 2.85 per cent.; Alberta increased 1,205,496 tons, or 25.45 per cent.; and reached its highest production on record. British Columbia increased by 134,703 tons, or 5.53 per cent. The figures of the production by provinces are as follows in short tons—Nova Scotia, 6,327,091; New Brunswick, 189,095; Saskatchewan, 355,445; Alberta, 4,736,368; British Columbia, 2,433,888; Yukon Territory, 4872.

Exports of coal in 1918 were 1,817,195, tons, valued at $9,405,423, an average of $5.17 per ton, as against exports in 1917 of 1,733,156 tons, valued at $7,387,192, an average of $4.26 per ton. Total imports of coal of all classes were 21,678,587 tons valued at $71,650,584, as against imports in 1917 of 20,857,460 tons valued at $70,562,357. There was an increase in the import of bituminous coal, but a falling off in the import of anthracite. The estimated consumption of coal amounted to 34,840,605 tons as compared with a consumption of 33,123,735 tons in 1917.

The total output of oven coke during 1918 was 1,234,347 short tons made from 1,945,475 tons of coal, of which 1,348,232 tons were of domestic origin and 597,243 tons imported. In 1917 the total output was 1,231,865 tons of coke, made from 1,928,923 tons of coal. At the close of the year 1560 ovens were in operation, 1041 were idle, and 115 were building. Exports of coke were 29,612 tons, valued at $223,629, as against exports in 1917 of 23,595 tons, valued at $137,318. The imports of coke were 1,165,590 tons, valued at $8,975,445, as against imports in 1917 of 970,106 tons valued at $6,517,260. The estimated consumption of oven coke was 2,363,270 tons, as compared with 2,192,373 tons in 1917. Of the total output of coke 879,063 tons, or 71.2 per cent. was made in byproduct recovery ovens and the byproduct recovery included ammonium sulphate 10,525 tons and tar 7,697,435 gallons.

Lignite coal can be cheaply mined, and the mines are generally free from explosive and dangerous gases. As a rule sulphur is not found in objectionable quantities in this fuel. Once started, lignite burns well—one drawback being that it needs more attention than the average bituminous coal fire.

Government's Purchasing Policy Leads to Controversy

Other chapters are being written in the controversy between the Director General of Railroads and the Secretary of Commerce as to the Government's purchasing policy. The discussion of this subject is being followed with the keenest interest by practically every industry. This is testified to by thousands of letters on this subject which are pouring into every Bureau in direct touch with industry and augmenting the mail of every senator and member of the House of Representatives. While the coal and metal mining industries and the makers of steel are affected more than are most other industries, it is clear from the communications reaching the capital that every community in the country is interested in the proper exercise of buying power. Secretary Redfield, in his most recent expression on the matter, says:

The various transportation elements include a controlling purchasing power over our industries and through them over our labor and our producers of raw material. It would lie in their power to injure or even destroy not one but many industries simply by either refusing to buy or by delaying buying at a critical period or by insisting upon impossible prices, or impracticable terms. Most business men will, I think, agree that it might make relatively little difference to industry who administered the laws or even what the nature of those laws might be if power over the life and death of industry lay in the hands of a few men because of their ability to purchase or to refuse to purchase its output.

This power, which is not so much by purpose as by its very nature autocratic, would be peculiarly difficult to reach and control by law because it is impracticable to regulate by statute when or how buying must be done. Procedure can indeed be fixed. Publicity can be provided and competition secured in form. The danger suggested, however, comes not from paying excessive prices but from the reverse, from forcing by the pressure of enormous buying power prices, terms and conditions of such a character as substantially to put our industrial fabric into the hands of masters of almost imperial power. Let there be given any one of you ability substantially to control one-third or more of the coal purchases of the United States through your predominant power in buying fuel and that industry becomes plastic in your hands. Let there be placed in the hands of another of you the power to purchase from one-third to one-half or possibly more of the products of the steel industries or of certain portions thereof and that industry becomes your servant, to do substantially as you will. The same is true of other great industries like copper, the shipyards and the builders of machinery. It will, I am sure, become clear to your thought after reflecting upon the incidental creation through Government operation of a unified buying power that there would be established an economic force so mighty as to work its will with industry and labor and to make them its creatures. It is not assumed that there would be intent to do harm. The reverse is undoubtedly true. It may indeed be taken as certain that as in the past and present so in the future conscientious and careful men would do the work. Ruin, however, can well be wrought by want of thought, by absence of social vision, by incomplete knowledge, by partisanship—involving either a party or directed to a service or a person, by the sense of irresponsibility arising from possible brief tenure of office or by the loss of balance arising from the intoxication of power. Years are not required to cripple an industry. It can be done in months or even weeks. There seems to be involved, also, the principles of democracy in commerce as against autocracy, with all that both imply, and the deeper one's thought goes into the matter the more one questions whether there would not be created an empire within the state which, however free in form the state might be, would of necessity control it from inside.

Continuity of operation in industry is essential to effectiveness and low cost. From the human standpoint it is more important still. It is essential to continued employment and to regular earning power on the part of labor.

Director General Hines, in an "I-told-you-so" statement, analyzes the earnings of some of the steel makers and concludes that "grossly excessive profits" are being earned. As Mr. Hines' statement is certain to be the basis of a fiercer phase in this industrial controversy and provocative of efforts to enact remedial legislation, it is reproduced herewith in its entirety:

When the Industrial Board approved the prices proposed by the steel interests it became at once apparent to me and I so indicated in various discussions with representatives of the Government that that approval would encourage the steel interests to stand together on those prices even though governmental approval was withheld. I felt, however, that even so it would be far more in the public interest for the Government to withhold approval and if necessary pay such prices, for the time being, under protest rather than indorse the prices, and that too for the entire calendar year, as was proposed by the Industrial Board, and thereby given an official sanction to prices which were unreasonably high and which would merely serve as a starting point for still higher prices later on.

The result has been in exact accordance with this forecast. Six of the leading steel interests, in response to the Railroad Administration's request for bids for steel rail, have submitted bids which are uniform in all respects as to prices and conditions of manufacture and are in strict accordance with the prices proposed to and approved by the Industrial Board. In view of the immediate need for 200,000 tons of steel rails, orders have been placed at the price thus indicated (that is $47 per ton for open-hearth rail) for that quantity with the Carnegie Steel Co., the Illinois Steel Co. and the Tennessee Coal and Iron Co., all of which are subsidiaries of the United States Steel Corporation, and with the Colorado Fuel and Iron Co., the Bethlehem Steel Co. and the Lackawanna Steel Co. This action is taken not only without approval of the prices but for the reasons shown below with emphatic disapproval of the prices and the manner of their establishment.

That action of these six steel companies in making uniform bids was taken under the leadership of the United States Steel Corporation is clear from the fact that immediately after the Railroad Administration announced finally that it would not approve the prices fixed by the Industrial Board, Judge Gary for the Steel Corporation took the initiative in announcing publicly that the Steel Corporation was strictly maintaining the prices approved by the Industrial Board and that it seemed to him that would be the attitude of other manufacturers. The subsequent action of the Steel Corporation and the other manufacturers in submitting their bids has accorded completely with Judge Gary's announcement.

The Steel Corporation's annual report to its stockholders shows that after paying all wages and other operating and maintenance expenses and allowing most liberally for renewals and paying interest on debt of subsidiary companies and also taxes other than war taxes and excess profits taxes it had net earnings on all rolled steel products of $21.58 per ton in 1916, $35.73 per ton in 1917 and $33.53 in 1918. It is a remarkable fact that in the calendar years 1917 and 1918 the net earnings of the Steel Corporation aggregated approximately $1,000,000,000, being in excess of the annual rental which Congress has sanctioned as reasonable for practically the entire railroad mileage in the United States. It is true the Steel Corporation had to pay out of these net earnings heavy excess profits taxes to the Government, but even after paying these taxes, making liberal allowance for depreciation, and extraordinary replacement funds, and after paying interest on bonds and 7 per cent. on preferred stock, there remained an earning of 39.2 per cent. on its common stock in 1917 and of 22 per cent. on its common stock in 1918. The fact that excess profits taxes were paid out of the net earnings in 1917 and 1918 does not in any way detract from the accuracy of those net earnings as a measure of the productiveness of the war prices which were charged by the Steel Corporation.

Estimated Costs Show Wide Variation

These figures of actual net earnings per ton on the entire output of the Steel Corporation are much more convincing than estimated costs of rolling a particular steel product at a particular mill. The estimated costs may show the greatest variation, but the ultimate result is an enormous profit to the stockholders of the corporation. The claim that the wages of labor would be endangered by a reasonable price on steel is therefore not convincing.

Heavy profits are not confined to the Steel Corporation. It appears that the net earnings of the Lackawanna Steel Co. were $12.40 per ton in 1916, $24.81 in 1917 and $19.88 in 1918; of the Republic Iron and Steel were $13.88 per ton in 1916 and $25.92 in 1917, and its profits for 1918 are not yet available; of the Colorado Fuel and Iron Co. were $9.57 per ton in the year ending June 30, 1916, and $13.91 per ton in the year ending June 30, 1917. The Bethlehem Steel Co. furnished no reports that give any information as to the profits per ton. In considering all these profits it must be remembered that the reductions from war prices which were proposed by the steel interests and are now being adhered to by them as the greatest reductions they are willing to make are practically completely offset by the great fall in the price of scrap iron alone (which can be and is used largely as a substitute for pig iron in the manufacture of steel) without regard to the various other reductions in cost which are coming about as a result of readjustment to peace conditions.

A seventh steel company, the Midvale Steel and Ordnance Co., in response to the request of the Railroad Administration for bids, proposed prices $10 in excess of the prices proposed by the other six companies. It is interesting to note that the company which made this proposal showed on all its steel products net earnings in 1916 of $24.62 per ton, in 1917 of $44.23 per ton and in 1918 of $35.93 per ton. Its apparent position now is that it cannot afford to make any reduction in the price of steel rail without reducing the wages of labor.

It is important to remember that the present policy of the steel interests in adhering to high prices on the ground that the present high costs necessitate these prices is a policy that does not work both ways. It is a policy to keep prices from going higher as business increases and costs diminish. It will be remembered that the Industrial Board announced that the public could not expect prices to be lower during this calendar year, but it gave the public no hope that they would not go higher. The resumption of business in the country will probably result in the substantial diminution in the cost of steel production, but unless the attention of the public is constantly centered on the situation there is danger that the steel interests will take advantage of the increased demand to increase the prices of steel still further, even in the face of declining costs.

The situation in the steel industry is of greatest moment to the American public. The United States Steel Corporation is the largest producer and controls approximately 50 per cent. of the output. It takes the lead in maintaining a price, which, if its reports to stockholders are reliable, indicates a grossly excessive profit, and it does this for the avowed purpose of protecting alleged high cost producers which, however, so far as they make detailed reports on the subject to their stockholders, also indicate large profits. In other words the Steel Corporation appears to take the position that for the protection of other prosperous steel producers it is unwilling to initiate any competition in the steel industry and naturally these other producers are glad to follow this lead, and incidentally this position enables it to continue the enjoyment of very high profits. This condition operates to suspend the law of supply and demand when it could work in favor of the consumer, but it leaves that law free to operate with the greatest effect when it can work in favor of the manufacturer. This situation also works to deprive the public of the benefits of the increased efficiency due to the great combinations in the steel business. Those combinations are the result of public acquiescence and yet all the benefits of them go not to the public but to the private owners. The more powerful the combinations become the more successful they are in keeping up prices.

These reasons lead me to reiterate that the prices in question are unreasonably high at present and will become progressively more unreasonable as business improves and conditions become more nearly normal.

Soldiers Realizing Opportunities

One of the difficulties the Federal Board for Vocational Education has encountered in its work of reëducation is that of convincing disabled men of the generous aid offered by the Government: That all expenses of retraining are paid and in addition the needs of wife and children supplied; that this is not considered a loan, but the payment of a just debt, and that their only obligation is to make good and useful citizens of themselves, seems too good to be true. But when the disabled soldier realizes that he is the beneficiary—not of public charity, but of national gratitude, he accepts the proffered offer of retraining with good grace.

Already there have been 81,741 men to register with the board, the vocational advisors have made contacts with 52,367 of these and 2079 have started their training under the guidance of the Federal Board for Vocational Education.

Of the 4376 cases approved for training by the Federal Board for Vocational Education over 1200 have been approved for trade and industrial training, 846 for agricultural, more than 1200 for commercial and business courses, about 850 for professional courses. Three hundred and ninety-two are taking academic training and 99 are studying in some special course.

All the Fuel Administration's regulations and orders pertaining to petroleum and petroleum products were vacated effective May 15.

Interior Department Exposition Arouses Considerable Interest

Wide attention has been attracted by the exposition being conducted by the Interior Department. The extensive lobby of the new Interior Building is being used for the exposition. If the present rate of attendance continues, it is believed that no less than 100,000 persons will have visited the exhibit.

One of the most striking features of the Bureau of Mines' portion of the exhibit is the display of all stages in the handling of metals and other minerals from the crude raw material to the finished product. Copper, nickel, tin, lead, antimony, zinc, potash, sulphur, mica, abrasives and other minerals are thus shown.

Gas masks, oxygen breathing apparatus, dust and fume respirators, as well as a complete display of the absorbents used in protection against gases, are on display. The explosives exhibit is one of the most complete ever shown, as is the display of types of mine safety lamps. A section of the Bureau of Mines exhibit shows how coal analyses are made and how fuel inspection is conducted.

Certain Essentials Necessary to Effect Fuel and Operating Economy

At the recent meeting in Chicgo of the International Railway Fuel Association, Eugene McAuliffe presented a paper on "Certain Essentials." While this was intended chiefly for railroad men, it nevertheless contained certain points of considerable interest to coal producers. Mr. McAuliffe spoke in part as follows:

"A year ago the Fuel Conservation Section of the American Railroad Administration was launched. The meeting held in Chicago in May, 1918, was really a revival with patriotism the dominating keynote. Many in attendance who were previously passive toward fuel economy pledged themselves to effort, and much has been accomplished in the year just passed.

"My caption, 'Certain Essentials,' signifies certain compelling features, which if attended to will accomplish more in one year toward effecting fuel and operating economies than has been accomplished in the past five years. Briefly, the outstanding essentials of the railway fuel problem, as I see them, are:

"*Clean Coal*—Buy clean coal, get clean coal. There is not a coal contract in existence that does not suppose the delivery of the cleanest fuel that the particular mine from which the purchase is made is capable of producing. Do not ask from the coal producer the impossible, but insist on the possible. Tests have proved that with coal containing 12.5 per cent. of ash taken as 100 per cent. the relative efficiency falls as the ash increases until coal with 40 per cent. of ash marks a total lack of efficiency.

"At the mine face, or on the tipple, is the place to clean coal. The removable non-combustible matter can be separated cheaper there than in the locomotive firebox. Cleaning coal of excessive rock, slate, shale and sulphur is a 'delousing' process. Let the producer do the cleaning; such is a proper item in the cost of production. I have found on a majority of roads an insufficient and frequently untrained inspection force. I find that the roads which most need an inspection force are most lacking one. Good inspection supposes many things, including contract, quality, weights, clean equipment and the proper class of equipment. Ninety-nine per cent. of the coal operators, all that are worth considering, will appreciate the help that an intelligent inspection force can give them."

Distorted valve motions, air leaks in locomotive front ends, distorted draft apparatus, clogged flues, grates and ash pans, the superheater, back pressure losses, and the old type of locomotive were then discussed, the speaker closing his remarks as follows:

"In conclusion, I wish to suggest the absolute importance of bringing every locomotive now in service, or that will be required for service, up to the maximum standard of efficiency. I have been told that the work of applying superheaters and brick arches under order, and in some cases, in stock, has been held up on certain roads because of insufficient funds. This is unfortunate, and I trust such a condition will be quickly remedied."

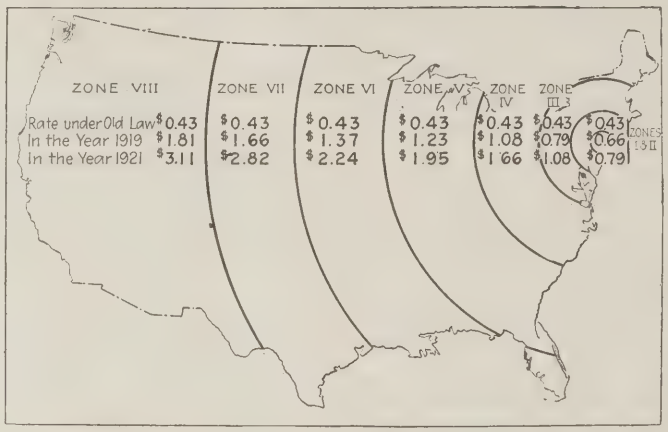
Expect That Poor Transportation Facilities Will Hamper Coal Output

Without in any wise being critical of the Railroad Administration, National Coal Association officials state that they fear that railroad transportation deficiency will interfere seriously with supplying the increasing volume of coal which must be produced during the latter half of the year. It is well known that only such repairs have been made to coal-carrying equipment as will keep it in running order. Thousands of cars have stood for six months without attention. In many instances motive power conditions are little better than are those of cars. Already car shortages are popping up here and there despite the large number of stored cars. It is believed that a considerable percentage of the stored cars can not be moved until repairs have been made.

Rumor of Government Control of Coal Believed to Be Unfounded

Reports in the daily press that the President expects to urge some form of Government control for the coal industry are believed in Washington to be unfounded. It is probable that they have their foundation in the fact that Secretary Lane has been asked to look around for the personnel of the commissions provided in the Garfield plan, which was the subject of a referendum taken by the National Coal Association.

Dr. Garfield says that President Wilson, after careful consideration of the plan, instructed Secretary Baker, while the latter was in Paris, to advise Secretary Lane to proceed with the formation of the commissions which are a necessary part of the plan. President Wilson said that these commissions, immediately after organizing, should begin the necessary studies relating to coal and all other raw material industries.



The Railroad Administration has issued a circular dealing with the storage of coal. Suggestions are made covering the proper method of storing to keep the cost of storage at the minimum and to reduce the hazard of spontaneous combustion. As it is estimated that the cost of transporting coal during the summer season is 60 per cent. of the cost of such movement during the period of extreme winter weather, employees are instructed to take those facts into account.

EDITORIALS

Government Tax on Western Readers

ON AND after July 1, 1919, subscribers of *Coal Age* residing in the western portion of the country must pay a substantial national tax for the sole privilege of living west of the Mississippi River.

On July 1, 1918, a benighted United States Congress enacted what amounted to a 17 million dollar bonus on ignorance. It decided that there should be no distinction so far as the mails were concerned between information and plug tobacco or other merchandise. It accordingly sectionalized the country and established a zone system in second-class postage, under which all newspapers and periodicals are carried. Nine-tenths of the literature perused by those who read or study technical subjects, so as to improve themselves and their industries, is carried under this classification.

The War Congress carefully divided the sheep from the goats—the distinction depending entirely upon geographical location. It separated the reading public of America into eight different classes. It decided that the people living in the eastern zones, where the nation's publishing is chiefly done, might secure their favorite periodical at comparatively small expense while those more remote should be progressively penalized until the point is reached where it becomes prohibitive to read anything except the local paper containing the latest town gossip. One concession (resembling the procedure of the boy, who, wanting to remove his puppy dog's tail without causing severe pain to the animal, amputated the member in small increments) was granted by these law-makers. They agreed to apply the thumbscrews gradually, the maximum pressure being attained in 1921.

Under the old law, or that in effect in 1917, it cost a flat 1c. per pound to mail *Coal Age* anywhere in the United States, or 43c. for the 52 issues of the year. Reference to the accompanying map will show present conditions and those that will exist two years hence. Even now the yearly postage alone on *Coal Age* mailed to the territory including and west of the Rocky Mountains is considerably over half the subscription price of the paper. The exorbitant postal charges established by this system actually erect a formidable barrier around each zone, effectively prohibiting the interchange of intelligence or information with the world outside.

This tax on intellect, this bonus on ignorance, since it was embodied in the War Revenue Bill we at first regarded as being purely a *war* measure. In company with other publishers and readers of publications we could not force ourselves to believe that it would be seriously considered after the stress of war had passed. And rather than impose upon our readers what we considered was a purely temporary burden, we shouldered it all ourselves, hopefully awaiting the repeal of this pernicious enactment.

We now learn that it is proposed to perpetuate this blunder, this monumental example of out-and-out class legislation.

It will be immediately apparent that although we have thus far carried the entire burden of increased postage no publisher can long continue to bear such an increased tax unaided. Therefore, beginning with July 1, those of our readers who reside west of the Mississippi River must add 50c. to their yearly subscriptions to defray in part the extra mailing charges. As will be seen, we are even then breaking much better than 50-50 with our western readers.

It is with deep surprise, mingled with no small amount of shame, that we learn that in this age of public schools and compulsory education men can be found (not to say be elected to posts of high responsibility and honor) who are willing to sectionalize the country, discriminate against the man who through force of circumstances must secure his "learning" through home study and hard knocks, and compel the ambitions miner or mine official to pay through the medium of zone postage on his favorite technical journal for such things as the free distribution of seeds to the farmer or backyard gardener by artful, politic, self-promoting politicians.

If you believe that the present zone system of postage is just, equitable, right and tending to promote the best interests of the coal industry, your community, your state and the country in general, you will "lie low and keep quiet." If, on the other hand, you believe it is none of these things, you will do exactly the opposite and demand from your duly constituted representatives in both houses of congress its prompt repeal.

A principal business for every man—coal man or other—is the nation's business. Industry needs to be speeded in slack periods, or the coal operator will not be prosperous nor the miner prosperous or contented.

The Reclamation Service is still running a mine at Williston, N. D. From state reports, we gather it is now leaving 42 in. of coal in the roof instead of 24 in. Yet we can still remember the time when government ownership was declared to be a complete solution for fuel waste.

Twenty-One Tons per Man-Shift

IN 1918 the average production per inside man in the anthracite region was 974 tons and in the bituminous region 1296 tons. The war made the figures large, and it is interesting to compare them with those showing the output in metal mines during the war period.

In this connection it may be noted that an extremely interesting figure was recently published by the Inspiration Consolidated Copper Mining Co. to the effect that the average production per mine worker at its shaft, which is located at Miami, Ariz., was 21 tons per man-shift. That, per year of 300 days, would mean 6300 tons per man. The ore is easy to mine, gravity delivers the material to the gangway chutes, and pulverization of the product is in its favor; but the figure shows how much more is being handled per man in some metal mines, even though in them payment by the day is the practice.

Anthracite must not be blown to pieces, and it doubtless takes more explosive to displace. The ventilation of the mines has to be speedy and positive. In the Inspiration mines, however, with its sulphide ores which are all the time oxidizing, the heat generated is considerable, and good ventilation is quite necessary.

What are the differences making for higher costs in the anthracite region? There are two main reasons: The methods of mining are different and the men in the metal mine do not mine by the ton. The Inspiration company, which pays by the day, uses methods made reasonable by reason of the use of day labor, so possibly there is only one real reason for the difference in cost, and that a difference in the method of payment.

An inquiry into the metal-mining costs and methods of Arizona would be well worth while. Some time ago an anthracite engineer made a trip of investigation. The report he made has never been given publication. All that has appeared has been something quite learned about the geology of the porphyries. The larger matter of interest was not treated, though it would be the main consideration to the coal-mining public.

Lest the point of this editorial be lost, we quote the actual words of Cornelius F. Kelley, president of the Inspiration Consolidated Copper Co., page 3 of the report of the year ending Dec. 31, 1918: "The average output of ore per man-shift for all the labor chargeable to the mining department was 21.5 tons." The comparison, we have just indicated, is at least interesting even if it be held to be not quite fair to the anthracite region.

Defeatism in National Business

THERE is a school of thought that is disposed to transfer Newton's law of motion, that "action and reaction are equal and opposite," into the domain of economic law. As the pedants of that school interpret its teachings: High wages are followed by low wages and high prices by low prices. The truth is that there is no evidence of any such law unless it is proved by the multitude of its exceptions.

Wages and prices have almost continuously risen for centuries. If action and reaction had been equal and opposite, there would have been no rise but a fluctuation between two limits. Instead, prices and wages have been lifted repeatedly and immensely, and have rarely been lowered in anything like equal proportion. It is true that some commodities, subject to the quickening hand of invention, and others, the value of which is determined largely by transportation costs, had risen but little in price, or even fallen, just prior to the war; but the law of action and reaction had nothing to do with this condition.

There is no sign of action and reaction in the quantity of currency, in the population or its consumption, in the amount of wealth or bank deposits. All these items have increased almost steadily from generation to generation. Nor is there any sign of rhythmic fluctuation back and forth about a given average in the currency per capita, the consumption per capita, the wealth per capita or the bank deposits per capita.

A doctrine like that propounded is a most distressing form of antisocial propaganda. It fosters a feverish fear of decreasing prices just when business needs a restoration of its faith. It is defeatism in business. It says in effect that it is useless to resist the inevitable reaction, that the times are earmarked for a depression. That lowering in wages and prices, that business collapses must come about by reason of laws beyond our human powers. Such fatalism is a danger to our body politic and a heresy that needs stamping out.

Overproduction may be followed by underproduction. But who will say that we have built too many houses, constructed too many railroads, equipped them with too many locomotives and cars, rerailed and retied the railroads with too great vigor, bought ourselves too many suits of clothes, dredged too many harbors or built too many roads. Why! we have been avoiding all these things for months, almost years, during the duration of the war. Never was there a time when we so curbed our desires.

There is no reason in a despicable defeatism of this kind that keeps us from a prosperous activity. It is not merely a psychological condition that we face but a false reasoning. If we will but shake ourselves, we can have done with the lethal dream.

They Have Gained Ground; but From Whom?

BEFORE the war, coal companies lost money or made negligible profits. Wages to mine workers were much lower than today. All increases of wage, therefore, must have come out of the consumer, who is either a manufacturer producing for sale to workingmen or is a workingman himself. It is idle to contend that combinations to increase wages are not combinations against the consumer and of one laboring man against another. This does not necessarily condemn such combinations, but it is a pretense for anyone to declare that they are in the interest of labor as a whole.

Such a combination is for the advantage of the group which organizes the combination, and justifiable only if used to defend a right and not as a means of attaining an advantage over other groups. The six-hour day, for instance, as a permanent institution should not be granted to one group while denied to another, or one group will serve the public six hours while the public is serving the first group eight hours.

It is true that there are employments where long hours are justified. There should not be too great a restriction as to the number of hours spent by a man asleep in a cabin, stretched out in a caboose, watching a lantern or nursing a danger flag. Like should be compared with like. The mine worker is justified in the

eight-hour day, and he should not seek to shorten it till it is reduced in other similar industries. He knows by this time who is his real paymaster—the public—and knowing it, he will not hide the fact from his eyes that he must not seek too high a wage or work too short a day. If justice is to be appeased, all men must throw an equal weight into the scale of production.

Unions are for defense just as are armies. They should not be used for offense. They are to establish justice, not to impose a yoke. They are to set an example, not to violate principles. Owing to labor-union action, there is a large section of the workingmen of the country who have been dispossessed of their former wages. They have not had wage increases proportionate to increased living costs; for this they blame the unions. The unions reply, "It is your own fault; you should have had a union yourself." The reply resembles one Germany might be supposed to have made to Belgium: "It is your own fault, Belgium, you should have had a strong enough army to repel our invasion."

These are unpleasant truths, and it is only fair to state that there is an immense amount of admirable idealism in the union. The average union man believes he is a pathfinder, leading not only the union but the non-union men also to a bettered condition of life. As a matter of fact, it is questionable whether by depressing output and by causing strikes he has not decreased production and so lowered the amount of distributable wealth. Many an admirably intentioned person has done harm rather than good. It is permissible to wonder whether the union man is not one of these, and whether his claims for having caused a beneficial reconstruction of the affairs of mankind are justified.

He sees his own lot bettered and says that it is a happy world and that he is setting a good example, when really some other body of workmen, less unionized, less large, or whose work is less vital, is ground to the wall by the collective action of the better unionized, more numerous and more vitally important operatives to whose collective action the public is obliged to bow. These organized men may not be supermen, but they nevertheless lay down the law to a sometimes too complaisant world.

Why leave the business of the country to politicians? The policies of the country should be directed by the productive elements of the Nation—by labor and capital—and not by those who arrange to fatten off both.

Bolshevism and Some Other "Isms"

EVER since the Russian débâcle the world has heard much of certain false principles then termed, for the first time, bolshevism. To the majority of us it is difficult to distinguish between socialism, communism, bolshevism and plain anarchism. All of these "isms" appear to shade into each other about as do the prismatic colors of the rainbow. Each nevertheless has certain points or phases wherein it resembles one or more of the others and each, it would seem, arises from a common selfishness.

We in America have long prided ourselves that John Jones had exactly the same rights and privileges and was held in exactly the same curb by the law of the land as was Sam Smith or Rob Robinson—in the body politic John Doe was just as good as and no better than Richard Roe. The social and economic system under which we dwell is similar and comparable to our principles of government. One man's money is exactly as good as another's; rewards for industry are measured solely by accomplishment, and each individual has as nearly an equal chance to better his condition as it is possible for human effort and organization to guarantee. The fair chance and the square deal for all are the two great objects sought. No power of man ever has made, or ever will make, any two individuals of the human or any other species exactly equal in strength, intelligence or ability. Nature does not deal in duplicates. The fact that one individual is stronger or keener than another is the result of nature or circumstances or both and is not chargeable to either the social system or the method of government.

Few will deny that our present form of government and economic state are the best that man has yet developed. They are probably the result of at least 10,000 years of experience in industry and the art of living. Despite all of this, however, the followers of, adherents to, or believers in, any or all of the above-mentioned isms inform us that the existing order of things is fundamentally wrong. They assure us that each individual should be rewarded for his effort, not according to the magnitude and efficiency of that effort, but according to the needs of the individual, regardless of the service, if any, rendered mankind.

To the disinterested onlooker this hue and cry appears much like the "kicking" of a "poor sport," like the groundless protest of a contestant in some athletic event who loses because he is too lazy to exert himself as energetically as his opponent.

Acquisitiveness is a universal trait. It is at once the common source of all wealth as we know it under our present social system and the mainspring that impels the "ismites" in espousing their pet theories. The adherents of socialism, communism, bolshevism, anarchism, or what not, want what they haven't got. They "want it bad" but not bad enough to work for it honestly as the man who now possesses it had to work for it. They proceed on the idea that the world owes them a living whether they earn it or not. They forget that in the very dawn of man's existence the stern edict went forth: "In the sweat of your brow shall ye eat bread." From that day to this no individual, family, tribe or nation has been able for long to avoid or escape this command and the perspiration mentioned—and as a general rule the more copious the sweat, the more abundant the bread.

America need have little fear from bolshevism. It is not indigenous or adapted to American soil. The early colonists in Virginia, once upon a time, tried a communistic experiment. Those who survived were well satisfied to go back to a more individualistic system of existence—the only system since the world began that has assured enough and to spare for those who were sufficiently industrious to put forth reasonable effort.

The people of the United States in the recent bomb outrage are getting a practical demonstration of the means and methods employed by the radical soreheads. It makes little difference by what name we call these extremists—we may judge of their motives by their deeds. Evidently they seek to rule without first having learned to respect and obey existing law.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

Operators who are losing their men to Europe in great numbers will be keenly interested in a bill presented on May 19 in the House of Representatives by Mr. Lufkin. (House Bill 61.) Mr. Lufkin would prohibit immigration for a period of four years. Certain exceptions, however, are made—"Government officials, their families, attendants, servants and employees, ministers or religious teachers, missionaries, lawyers, teachers, students, authors, chemists, civil engineers, artists, physicians, and travelers for pleasure, business or curiosity, or their legal wives or their children under 16 years of age who shall accompany them or subsequently apply for admission with the purpose of joining them."

This bill practically excludes all those who would be likely to join the ranks of mine labor and practically admits all those who might possibly stir up trouble. Alien lawyers, teachers, students and authors are often extremely undesirable citizens, whose sole aim in life is to set their fellows by the ears and create dissatisfaction. It seems almost impossible to comprehend why we should admit the lawyers of foreign lands. The thought presses on us that the act will strain out the workers and let through all the trouble makers and labor exploiters. It is well known that much of the dissatisfaction of aliens with American conditions is due to ill treatment of labor by educated sharks of their own nationality whom the laws only inadequately restrain.

Another clause admits otherwise inadmissible aliens "who shall prove to the satisfaction of the proper immigration officer or the Secretary of Labor that they are seeking admission to the United States solely to avoid religious persecution in the country of their last permanent residence whether such persecution be evidenced by overt acts or by laws or government regulations that discriminate against the alien or the race to which he belongs because of his religious faith."

This exception has little effect on the mining industry for the religiously persecuted who arrive in the mining regions—to dig coal at least—are few. A few Doukabors, or spirit wrestlers, might possibly find their way to the mines, though they are farmers rather than mine workers. But it is possible that the Russians will no longer persecute them, now that the Russian state church is overthrown. The religious behavior of the Doukabors is most objectionable to us, and if they came here they would probably be more severely persecuted in our villages than in those of Russia where the moral law is not so closely enforced. In Canada they have been driven by droves into jail.

A few persecuted "Old Catholics," also from Russia, have come over in the past and found their way to the mines, and, while hard to deal with, they make good workmen, but they are extremely few in number. A few Serbians and Bulgarians may also be expected for there are many religious and ethnic quarrels and injustices where their populations overlap.

But these possibilities are interesting rather than important. The majority of those who are here and will come here as an outcome of religious persecution are found now and will be found hereafter in our big cities. The mining region will not draw labor strength from among them. After the war perhaps the dominant churches of the past may be persecuted by the adherents of no faith at all in a degree and manner recognizable by the Secretary of Labor, but this is hardly likely, and it seems therefore, as far as the mining region is concerned, that the act practically excludes all alien workmen. Before the war, under such an act as this Jews, Armenians and Syrians would have been practically America's only visitants, and they would all have flocked to the big cities. As Armenia and Syria will now be in the hands of friends, the Hebraic people will probably be the only would-be immigrants who will be admitted under the provisions of the Lufkin act, if the law is passed. From them the mining population will not receive any noticeable accretions. Perhaps it will be admissible to point out that it is no more excusable to persecute persons for their racial origin than to harry them for their religion, or for both their race and their faith, and if the gate is thrown open to the victims of ethnic persecution a somewhat larger number of aliens will be admitted.

There are exceptions in the act which permit skilled labor to enter as under the third section of the act of Feb. 5, 1917, and also providing for the admission of those who come under the joint resolution of Congress of Oct. 19, 1918, which authorizes the readmission of certain aliens who have been conscripted or have volunteered for service in the armies of the United States or cobelligerent forces.

This proposed enactment needs the careful attention of all employers. If it seeks to prevent the Bolsheviki from entering the country it may be well said that it seems hardly likely to effect that result. Only complete exclusion of all aliens, persecuted and unpersecuted alike, will do that. Such a drastic step Mr. Lufkin hesitates to take.

ILLINOIS MINERS NOT TO PAY DUES TILL SEPTEMBER

Illinois members of the United Mine Workers will not have to pay organization dues during June, July and August unless the local itself insists on the payments for its own fund.

Frank Farrington, president of the state organization, has so advised the 350 local unions in Illinois. It is expected that the action will reduce the burden of the high cost of living for 85,000 men while work is slack.

The notice says "if work does not improve during the three months named, the executive board will give consideration to the matter of extending the period, otherwise local unions must resume the payment of per capita tax and the 1 per cent. assessment to the district office for the month of September."

The first labor celebration held in Ziegler, Ill., since the historic miners' strike there 15 years ago, was held during the past week. The mine is now completely unionized. The particular occasion for the celebration was the inauguration of increased passenger service on the Illinois Central R.R. Addresses were made by President Frank Farrington of the Illinois Mine Workers and others. Ziegler is now a town of 3000 inhabitants and is growing rapidly. Joseph Leiter has just completed his $1,000,000 mine, which will employ 1400 men when fully developed. It is claimed to be the most modern colliery in the United States and is planned for a daily capacity of 8000 tons.

SOME PETTY ANTHRACITE STRIKES

Two brief strikes occurred in the Lehigh field during the week. The contract laborers in a section of Hazleton shaft colliery of the Lehigh Valley Coal Co. went out and returned three days later. The colliery was idle for nearly the whole week due to this cause and holidays. The steam shovel crews at Jeddo No. 4 colliery of the G. B. Markle Co. tied up that colliery for a day because back pay awarded by the "umpire" was not paid on the current pay-day. The matter was speedily adjusted and the colliery resumed work after a day's idleness.

Three late strikes in the Lehigh field have been brought about by the impatience of employees with the matter of the settlement of their grievances. Compared to the average county court, the board operated in a swift manner, and it seems pure folly to tie up a plant in order to hasten

a proceeding in which the union and the company are both factors and share in the tardiness of their board members.

Conditions and Unrest in Illinois

Riding to work in a high powered car is the latest fad among coal miners in the Connellsville region. The improved conditions among the laborers of the region were made possible by the wage scale which is yet in effect although overtime has been eliminated. Some days ago three Poles asked Superintendent Charles Opperman of Orient for a job. They got one as coal diggers. The next morning a graceful smooth running car valued at about $3000 rolled up to the pitmouth and the three poles got out, unloaded their tools from the rear of the machine, preparing for their day's work as if they had been accustomed to just such things all their lives.

A call has been sent out to 246 locals of District 11 to meet in the Pythian Temple in Terre Haute, Ind., July 8. This will be the 27th consecutive and the 4th annual convention of the district. More than 200 delegates are expected to attend. Officers of the International Mine Workers' Union have been invited to be present.

Mining conditions in the Carterville district, Williamson County, Ill., are reported to be dragging, most of the mines hardly averaging two days a week. The labor situation was slightly relieved recently when the "Burr" mine resumed operations after being closed down for some three months. Mines 3, 8 and 9 of the Madison Coal Co. near Marion are reported as working from three to five days per week.

One hundred miners working at the West Virginia Coal Co.'s mine at Murphysboro are out on strike since Saturday, May 24. The reason the men give for striking is because Superintendent John Henderson, of St. Louis, refused to give a bond for guaranteeing their wages and they state that Henderson has failed to meet President Farrington, of the Illinois miners, for the purpose of arranging a bond to guarantee their wages. The West Virginia company operates eight other mines besides the one at Murphysboro, two being at Marion, one at Coulterville, one at O'Fallon and four near Belleville. It was thought at first when the Murphysboro strike occurred that the men working at the other mines of the company would strike also, but so far they are still at work at the other places.

Four hundred miners came out on strike Monday, May 26, at the mine operated by the Wasson Coal Co. at Harrisburg, Ill., and indications are that the men working in the mines near there will follow shortly. The trouble arose because C. M. Wasson, president of the company, signed an appeal bond of the Evans Coal Co., which recently went bankrupt while owing money to the men employed.

The treasury of the local union connected with mine No. 7 of the Big Muddy Coal and Iron Co. at Herrin, Ill., needed replenishing and the men voted to levy an assessment of 25 cents per man for that purpose. The mine officials found nothing in their agreement to permit this and refused to collect the funds. The result was that the men went out on strike and stayed out for a week before an agreement was reached.

Want Eleven Hours Pay for Eight Hours

On May 23 it was reported that the coal miners of District 18, which comprises eastern British Columbia and the Province of Alberta, would strike on Saturday, May 24, as a result of a disagreement which has arisen in the Crow's Nest Pass section of British Columbia over the pay of some employees whose working time is reduced by the recently-enacted Eight-Hour Day law, a regulation passed by the parliament of the Province of British Columbia. About 6000 men were expected to walk out, of which number 1600 were resident in the Crow's Nest Pass.

The trouble arises wholly in regard to the wages of the surface men, for the law has for some time made the eight-hour day compulsory underground. But the trouble really revolves only about 12 men, for the company has conceded that the bulk of the surface workers, whose day previously consisted of nine hours, shall have the same pay for eight hours, but it refuses the same concession to foremen and others who have been working ten and eleven hours a day. The unions have had the matter under consideration for several weeks and, by an overwhelming majority, voted in favor of striking to uphold the claims of all workers to the same daily rate of pay under the Eight-Hour Day act as has been received heretofore.

According to the report of May 23 not only the miners but all the surface workers, including the engineers, were to be called out so that the situation in the colleries throughout District 18 would be serious unless some compromise could be reached without much delay. W. H. Armstrong, director of coal mining operations, endeavored to bring about a settlement, but his efforts were apparently unsuccessful, for on May 29 it was recorded that all the mine workers were out and that the railroad workers of Fernie with the Civic Light and Power Plant employees had struck in sympathy.

The British Columbia Federation of Labor recently telegraphed the Hon. G. D. Robertson, minister of labor, Ottawa, as follows:

"The executive board of the British Columbia Federation of Labor considers the refusal of an investigation into the condition of men who, by provincial legislation, are working eight hours in coal mines instead of eleven, and as a result have had their daily earnings reduced, is an action similar in effect to that which led to the Winnipeg strike. If nothing is done for these men and a strike results the Federation will be compelled to render them support in the only way possible. We have no desire to see any trouble in the West, but consider that the only way in which a strike can be averted is by granting an investigation."

Miners Clash on Zoning of Railroad Coal

Vigorous protest has been made to the Director General of Railroads by President F. C. Keeney of District 17, United Mine Workers, against the proposal to prohibit the Pere Marquette and other roads from purchasing West Virginia coal on the ground that the restriction would reduce the working time in West Virginia. A conference between President Keeney and President Moore of the Ohio United Mine Workers with Director of Purchases Spencer of the Railroad Administration has been suggested, the Ohio mine president being in favor, it appears, of the move to prevent the use of West Virginia coal on Western railroads. The president of District 17 has not only lodged a protest with the Railroad Administration, but with the international headquarters of the mine workers.

Strike for Electrification of Incline

About 300 miners employed at the Sprague and Skelton mines of the New River Co. in Raleigh County, West Virginia, went on strike and tied up operations for a week because the company refused to put in writing an agreement to electrify its switchback system. When District Inspector Sullivan visited the mines named above he found that 80 and 90 men at a time were riding the trips up and down the incline, whereas the law limits the number to 10. He immediately ordered the practice discontinued and a trolley system put in. This the company agreed to do, but miners insisted that the agreement be made in writing.

When the company refused to establish such a precedent the men went on strike and remained out for a week, W. J. Heatherman, chief of the department of mines, being called in to adjust the differences between the company and the miners. The men at one of the mines finally agreed to return to work on May 27, but miners at the other mine were still obdurate. The district officials were not a party to the strike. Committees of the miners stated in the course of a hearing that they no longer recognized any agreements covering the period of the war as being in effect or binding on them as the war was over. It is estimated that the company lost $18,000 by the strike, as it had on May 28 a vessel at tidewater waiting to be loaded.

DISCUSSION BY READERS

EDITED BY JAMES T. BEARD

World's Production Record

Letter No. 1—Being a constant reader of *Coal Age,* I noticed the statement in an article relating to the development of a large coal field in England, that a certain mine near Mansfield "holds the world's record for output in a given time, 4850 tons having been brought to the surface in 7 hr., 40 min." *Coal Age,* Mar. 27, p. 567.

Appended to this statement, I was glad to see the footnote inserted by the editor, drawing attention to some American operations, namely, the Orient mine, of southern Illinois, and Vesta No. 4, near California, Penn. Allow me to add that the "Old Ben Mining Corporation, Mine No. 9, at West Frankfort, Ill., holds a record of 5305 tons of coal hoisted in 7 hr. 45 min., with 1386 dumps. This record was made in a single day's run, Feb. 18, 1919.

This mine has a remarkable average record of over 5000 tons of coal hoisted each working day throughout the months of February and March, with the exception of one day when the accident of a broken cage caused a shutdown at 1:30 p.m.

Regarding the reference made in the footnote just mentioned, allow me to say that our Orient friends have a 4-ton car, against our 3-ton cars. This fact gives them the advantage in the line of daily production. However, we are all proud that the world's record is held by mines in our town. MINE MANAGER.

West Frankfort, Ill.

A.-C. vs. D.-C. Current in Mines

Letter No. 2—Some time ago, I read the letter starting a discussion of the use of alternating as compared with direct current in the operation of a coal mine, *Coal Age,* Feb. 20, p. 372. Since then, I have been hoping to see a number of letters on this subject, which I consider is an important one in its relation to mine safety and the economy of operating. It is disappointing to see how little interest the letter aroused among mining engineers and mine electricians.

It may be and probably is true that many, like myself, hardly feel capable of discussing the relative merits of these two types of electricity in mining, either from a theoretical or a practical standpoint. Personally, I have had several years' experience in the use of direct current in mines, but cannot say the same with respect to alternating current. For one, therefore, I would be glad to see this subject thoroughly discussed by those whose knowledge and experience are valuable.

The letter to which I have referred draws attention to the question asked at a recent meeting of the Coal Mining Institute of America; namely, "Is the underground use of alternating current more hazardous than the use of direct current?" With what little experience I have had in the use of alternating current, it is my belief that there is really less danger, or I would say there are fewer accidents occurring in mines using alternating current than in mines where direct current is employed.

This statement may be challenged by many to whom it will appear strange, but it is the result of my observation, and I attribute the reason for fewer accidents being recorded with alternating current to the fact that mine workers have generally more respect for that current than they have for direct current. The latter is often made the means of playing practical jokes on fellow workers.

In a mine in this field where direct current was used, little thought was given to a man or a mule coming in contact with a live wire, in the general performance of his work. Since the direct current has been replaced by alternating current in that mine, however, a wide difference is observable. The men now have more regard for live wires, as they are not anxious to come in contract with them. Neither is there any fooling or playing with the wires by the practical joker.

DANGER DISREGARDED IN USE OF D.-C. CURRENT

This condition would seem to warrant the assumption that while the danger of alternating current is greater in case one comes in contact with a live wire, at the same time, if the recognition of the danger makes men more careful when working around wires carrying alternating current, it may be true that there is actually less danger in the use of alternating current than in that of direct current. Statistics ought to show whether or not this is actually the case, and I hope these will be forthcoming before this discussion is closed.

In conversation with another operator, in this field, he expressed the opinion that miners are more liable to become careless where direct current is employed than where the mine is equipped with alternating current. He stated that the general belief among miners is that if a man comes in contact with a live wire in the former case, he would be knocked down and thus lose contact with the wire; but an alternating live wire would hold the man coming in contact with it, and he would be unable to break away.

Now, whether or not this is true, I will not say. However, if it will keep men from taking chances that may result in injury or death, it is well that this belief prevails. The old saying is true in this case. "Where ignorance is bliss, 'tis folly to be wise."

When visiting mines where alternating current is used, I have invariably observed that the wires are strung in the air-course or in a blind entry that is not used as a travelingway. Where these wires are strung on a haulage road or in any passageway where men must travel, I have noticed that they are hung close to the rib and protected by boards or other means. High power lines are frequently heavily insulated. These extra precautions are not taken generally in mines employing direct current, as far as my observation goes.

Mining men who advocate the use of alternating current for general purposes in the mine, give a number of good reasons why this should be done: (1) Ease of

transmission. (2) Less motor trouble due to the burning out of armatures. (3) Less frequent machine repairs required because of the overloading of coal-cutting machines. These and other good reasons are advanced in favor of the use of alternating current.

It is probably true that many *Coal Age* readers have had much experience along this line that would be of interest to us all, and it is to be hoped that we shall hear from such. Some years ago I worked in a mine in West Virginia where 500-volt direct current was used for hauling coal with motors, and a 60-cycle, 3-phase, 300-volt, alternating current was used for cutting the coal, pumping and operating booster fans. I would like to hear an expression of opinion as to which of these installations is the more dangerous in mining practice.

Cleaton, Ky. OSTEL BULLOCK.

Barometer vs. Outflow of Gas

Letter No. 4—Referring to the letter of E. P. Brennan, *Coal Age*, Apr. 3, p. 634, the writer seems to be in doubt as to the reason for the slowness with which barometric changes take place. He appears to ask why it is that the indications of the barometer are late; or, in other words, why it is that an increase of gas is detected in the mine, before there is any apparent change in the barometer. According to his statement, Mr. Brennan cannot understand why a properly constructed barometer will not adjust itself simultaneously with any change in atmospheric pressure.

After revolving this question in my own mind, it seems to me that the late response of the mercury column to atmospheric changes is only what should be expected. The barometer is a mechanically constructed instrument and naturally takes a little time to react, under a change of pressure that would affect a body of gas very quickly.

Practically speaking, I believe that the gaseous condition in mine workings may become very dangerous, before its cause is indicated by an observed change in the height of the mercury column. If I am wrong in this conclusion I should be glad to be set right. It is a matter of much importance in its relation to the safety of the mine. JOSEPH R. THOMAS.

Plymouth, Penn.

Reducing Ventilation at Firing Time

Letter No. 8—Many interesting letters have appeared in *Coal Age* discussing this subject, and a wide diversity of opinion is manifest. From reading the arguments set forth by the writers in favor or in opposition to this method of reducing the liability to explosion in mines, one would be unable to decide which is right or wrong.

Personally, aside from the seriousness of the subject, I cannot help being amused at some of the criticisms that are offered by opponents who contend that such a method is dangerous to employ in the operation of a coal mine. Studying the subject from their viewpoint, I cannot but feel that these opponents are radically wrong. Otherwise, I must have a charmed life, being the originator, as I believe, of this system and having practiced it for many years. Let me say that if the arguments presented were true, I would not be here to write this letter.

A few of the older readers of *Coal Age* will remember that some 5 or 6 years ago, I gave at some length, my experiences in experimenting on this method of reducing the liability to explosion caused by the firing of shots in mines (*Coal Age*, Vol. 2, p. 838; Vol. 3, pp. 24, 156). All will agree that the experiments recorded in those letters contradict everything that we have been taught in regard to the prevention of dust explosions in mines.

However, those experiments and an experience of 42 years in coal mines, together with an education that enabled me to secure first-class certificates for every position in coal mining, have convinced me that the system is correct and that its opponents are deluded and have not discovered the fundamental principle underlying the origin of these explosions.

My greatest ambition has been to prove to mining men that, to reduce the ventilation in a mine, at the time of firing, lessens the chance of an explosion occurring as the result of blasting. Following up my experiments, two years ago I accepted a position as shotfirer with the Central Coal & Coke Co., Mine No. 45, Crawford County, Kan. Prior to that time, the mine had had many explosions in which shotfirers had lost their lives.

THE PRACTICAL TEST APPLIED IN A GASEOUS MINE WHERE MANY EXPLOSIONS HAD OCCURRED

Deciding that this mine would make a good testing station where the danger of dust explosion could not be disputed, I applied the method of completely shutting off all ventilation from the working places, before firing the 300 shots in 2½ hours each night. Such had been my practice during the past 28 years, in the worst mines in Kansas, including Mine No. 15 of the Western Coal & Mining Co., at Franklin, which holds the world's record for explosions.

Mine No. 45 where I am now employed contained unlimited quantities of inflammable coal dust, many of the places being marked up each morning, by the firebosses, as containing firedamp. The practice was to blast the coal off the solid. Many of the holes were drilled 8 ft. on the solid, being started in the back of the cutting. About 80 per cent. of these holes were charged with black powder, the average weight of charge being 6 lb. The remaining 20 per cent. were charged with dynamite, such holes being drilled straight in the solid. In firing the shots, I used fuse and would light as many as 40 shots at once.

I do not imagine that anyone will question these statements of facts, but I invite investigation, with the full consent of the management of the mines, and will demonstrate that an explosion cannot occur in this mine when the air is shut off.

But someone will ask, here, "Has an explosion occurred in Mine No. 45, during the two years of your employment as shotfirer?" I answer, "Yes." An explosion occurred in one instance when the foreman had been instructed to make a new air connection in a position that made it impossible to cut off all the air.

A shot had been prepared in that place and, while it conformed strictly with the requirements of the mining law, I refused to fire it, unless a sufficient length of fuse was provided to enable me to reach the surface before it would explode. I predicted that the shot would cause trouble. The mine foreman complied with my demand, and I ignited the fuse and was on top when the shot

went off. The explosion blew the trapdoor into a thousand pieces, and caused other wreckage.

My contention is that explosions do not occur now in this mine, because the chief factor producing them has been removed by completely cutting off the ventilation from the mine, at the time of firing. It is my hope that these experiments will prove of value to shotfirers who are striving to protect themselves to the best of their knowledge and ability.

Ringo, Kan. ALEXANDER MCALLISTER.

Roof Conditions in Longwall Work

Letter No. 4—Referring to the proposition presented in the inquiry in *Coal Age*, Mar. 27, p. 591, it appears to me that the conditions mentioned there are ideal for longwall working if proper care is taken in performing the work. Those familiar with this system of mining know that it is important that no posts be built into the packs or permitted to stand in the waste, but all timber must be drawn as the face advances, in order to allow a uniform and gradual settlement of the roof.

The plan I prefer to adopt, in working a longwall conveyor face on the advancing system, is that shown in Fig. 1. This plan differs from that often shown, in

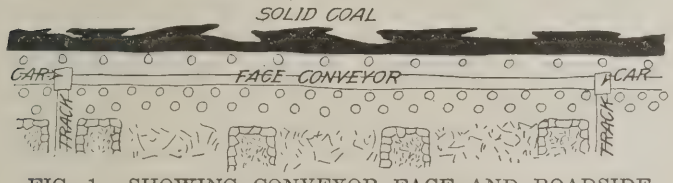


FIG. 1. SHOWING CONVEYOR FACE AND ROADSIDE AND GOBPACKS

one or two respects. First, besides the ordinary roadpacks, there are one or more continuous gobpacks. The roadside packs are usually 9 ft. in width, while the gobpacks may vary from 9 to 15 ft., in width, according to the amount of material on hand for building them.

Again, as shown in the figure, the conveyor is here laid between the first and second rows of posts, instead of in front of the first row, which affords a better support of the roof at the coal face. It is my belief that building the gobpacks, previously mentioned, affords a more uniform settlement of the roof and goes far toward preventing any sudden breaking of the roof at the working face. These packs must be well built though not too solid, and extended regularly as the face is advanced. Timbering should be conducted in such a manner as to throw just enough pressure on the face to break down the coal after it has been properly mined. As stated in the reply to this inquiry, the roof should not be permitted to break at the face if this can be avoided.

FIG. 2. SHOWING CROSS-SECTION AT CONVEYOR FACE

Fig. 2 is a cross-section of a conveyor face. On the left, is shown the coal undermined and the position of the conveyor between the first and second rows of props. On the right, the mined coal has been loaded out and the first row of props and the conveyor moved forward. The posts in the last row must now be drawn and set next to the conveyor, and the packwalls extended.

If the fireclay is of a good hard material, it will serve to make good packwalls. I have found by my own practical experience that there is none better. But if the fireclay is of a soft nature and crumbles readily when exposed to the air, it may be necessary to brush the roof in order to obtain good material for the packs.

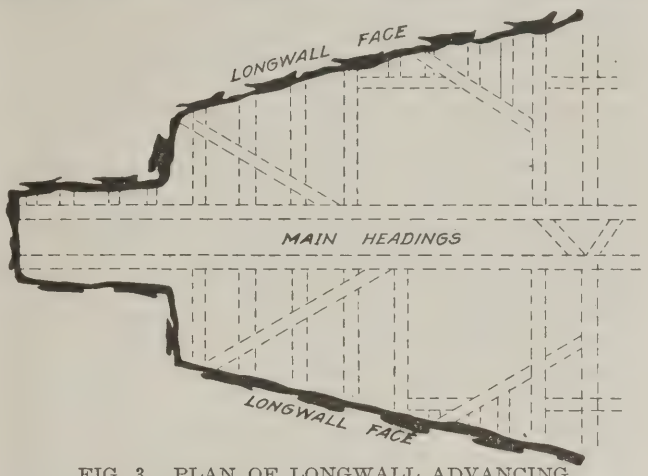

FIG. 3. PLAN OF LONGWALL ADVANCING

The hard sandrock overlying the coal is not good for packing, as it does not yield sufficiently to permit a gradual subsidence of the roof. The soapstone overlying the sandrock stratum makes better material and some sandrock can be used with it in building the packwalls.

In Fig. 3 is shown a plan of longwall advancing where no conveyor is used. In this plan, the gateroads are driven on 42-ft. centers, packs 8 or 9 ft. in thickness being built on each side of the road. Here, the cars are taken to the face where they are loaded by the men working each place. Under some conditions of roof, in longwall working, it is necessary to adopt a retreating plan and work the coal out in panels.

In Fig. 4, I have shown a panel system employing a conveyor face in each panel. This plan I have found

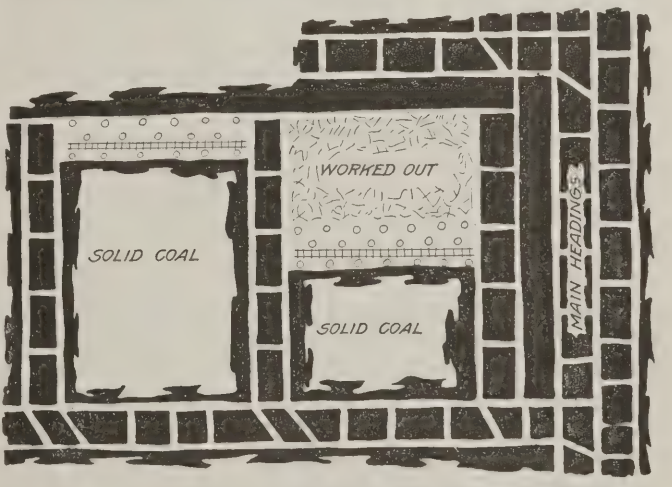

FIG. 4. A LONGWALL-RETREATING, PANEL SYSTEM

to work successfully where the nature of the roof requires the adoption of such a system. The main entries are driven three abreast and cross-entries turned to the right and left of the main entries, at suitable distances apart to form a good panel, say 100 to 150 yd. in depth.

As shown in the figure, a pair of butt headings, Nos. 1 and 2, are turned off the first pair of cross-entries, No. 1 butt being driven through into No. 3 cross-entry.

The purpose of this is to provide an extra air-course for the better ventilation of succeeding panels. A good pillar is left between these two butt headings, for the protection of this air-course.

Nos. 3 and 4 butt headings are now driven, at a distance of 300 ft. from the first pair of butts. This leaves a panel face of about 290 ft. in width. When these butt headings have been driven to the limit the panel is cut across at the face, and the work of drawing back the coal, on the retreating system, is commenced. A conveyor is used to convey the coal to the butt headings in the usual manner, and three rows of posts are kept behind the conveyor, to afford better protection at the working face.

At times, it is preferred to use a track along the face, instead of a conveyor. This track is supported on steel ties and is moved up as the face advances. Cars are then placed along the face as required by the men. Other panels are formed and worked in a similar manner; but when the second block has been worked out, the pillars between Nos. 3 and 4 butt headings are drawn back. The work of robbing the pillars should proceed as the panel of coal is taken out, which is far better than to allow the pillars to remain until the panel is finished. Each panel is drawn back to within 50 ft. of the cross-entries, so as to leave a sufficient pillar for the protection of the entries. WILLIAM DICKINSON, SR.

Oak Hill, W. Va.

Letter No. 5—In presenting his proposition for suggestions, *Coal Age*, Mar. 27, p. 591, "Sandrock" has omitted to give some important data, such as the depth of cover, inclination of seam, presence or absence of water and gas, etc. Any suggestions offered must therefore be based on assumed conditions.

This being a thin seam, only 3 ft. 4 in. in thickness, either a conveyor must be used to convey the coal to the head of the main road, or gateroads must be built and kept open, at short intervals along the face. Assuming that the seam is flat or nearly so, it may be supposed that mules are employed for gathering the coal at the face. In that case, I would arrange to make the main roads 200 ft. apart, with temporary roads or gateways 50 ft. apart. One mule would then be able to haul the coal from the three gateroads belonging to each main road, which would provide a good gathering haul for the mules.

TAKING UP THE CLAY BOTTOM PREVENTS HEAVING

By taking up the 3 ft. of fireclay, 10 ft. wide on the main road and 7 ft. wide on each gateroad, sufficient material would be supplied for building good roadpacks and, in addition, any trouble from the heaving of the floor would be eliminated. The 9 in. of sandrock overlying the coal would form a good support for the soapstone stratum immediately above.

It is my opinion that the sandrock in the overlying stratum would have sufficient elasticity to bend with the weight of the overburden, assuming a good depth of cover overlying this seam. In that case, the subsidence of the roof following the extraction of the coal would act as a lever to break down the coal after the face is mined.

At intervals of 200 ft. along the main road, diagonal roads should be started; and these, by cutting off the temporary roads or gateroads, would shorten the haul and liberate much tracking for use elsewhere in the mine. Probably this would also save much back brushing required to keep these gateroads open.

Let me say, here, that it is not good mining practice to attempt to pack all void places solid, in longwall work. In the plan I have suggested, there would be a good waste between the high-side pack of one road and the low-side pack of the road next adjoining, 50 ft. away As has been stated by other writers, all timber must be withdrawn from the waste, as fast as the working face advances, so that the only timber standing will be the temporary supports or rows of posts required at the face.

THE USE OF TIMBER COGS IN LONGWALL

Where cogs are used, one row of these is sufficient between the conveyor and the waste when operating a conveyor face in longwall. This row of cogs should be drawn and moved up as the face advances, so as to furnish the necessary protection for the conveyor. By this means, the roof has a good chance to sag down gradually in the waste, which will relieve the packs of a great deal of pressure and bring the desired leverage to bear on the coal face, which is the great concern in longwall work.

Referring to the practice of building a cog, to form the corner when starting a new packwall, it is my belief that this is a wrong method to pursue. The unequal resistance offered by the cog, which is always greater than that of the packwall, has a tendency to throw the weight too far forward on the face of the coal. This is frequently the direct cause of the roof breaking off at the face, which would defeat the chief aim of longwall work. It seems hardly necessary to add that a longwall face should be kept as nearly as possible in a straight line and not allowed to get zigzagged. Also, packwalls should be kept close up to the face.

Merritt, B. C., Canada. J. TOUHEY.

Living Conditions at Mines

Letter No. 3—I read with pleasure the letter of A. A. Allen, *Coal Age*, Feb. 13, p. 331, and later that of "Optimist," April 17, p. 726. Like both of these writers, I have spent my life around the mines, living in three countries, during the past 31 years. I have always been an interested reader of the accounts of large coal companies doing good work in the improvement of living conditions at their mines.

To some who have regarded this matter with less interest, no doubt the idea of making extended efforts for the improvement of the living conditions of men working in mines may seem unnecessary and radical, but it is my belief that much good is and can be accomplished when these ideas are carried out faithfully. But it will be useless to improve the living conditions of miners and their families, unless equal effort is put forth to give the men a square deal in the mine. Generally, fair treatment of the men by the bosses will bring equally fair treatment of the company on the part of the men, which makes it a business proposition for both parties.

Beginning at the mine, everything should be done for the comfort and welfare of the men. As the old saying puts it, "Cleanliness is next to godliness"; therefore, a good wash-house at the mine is especially necessary and should be provided. Here, the men should be taught to wash themselves and change their clothing

before going home. This little item will prove a great factor in maintaining neat homes and surroundings in the camp.

For all the men, there should be provided comfortable houses where they can live with their families and enjoy pleasant surroundings. These houses should be equipped with lights, running water, bathrooms and living rooms. Each house should stand on its own lot and have its own garden and lawn. Good roads should be maintained in the camp; churches, schools and entertainment halls provided to make it a good place in which to live.

Speaking of schools, these should be equipped for the accommodation of both day and night students. At the night sessions, instruction should be given in the English branches and special efforts made to implant American principles in the mind of each student young and old. First-aid and mine-rescue work should be taught and rescue teams organized. The entire work should be conducted so as to inspire keen competition in the line of efficiency.

Provision Made for Recreation and Entertainment Always a Good Investment

Mention has been made, in the letter by "Optimist," of the average miner being a hard worker and showing the same spirit at play. For this reason, athletic sports, baseball and football fields, as well as playgrounds for the kids, must be provided in every good mining camp. For indoor recreation, there should be a gymnasium. A large hall could be erected at small cost for the purposes of entertainment, dancing, picture shows and other amusements.

Welfare work among the miners is not complete without a good company doctor, supported by the monthly subscriptions of the miners rated in proportion to their family needs. Also, a company or coöperative store should be maintained where the best grade of goods can be procured at the lowest possible prices. A coöperative store should be under the control or governed by a committee of miners and bosses, elected every year or half year.

As I have said previously, these ideas may appear somewhat faddish to some; but they can be handled in a manner to make each effort self-supporting, and the benefit to the men and their families will be found far-reaching and of equal advantage to the industry.

Clinton, Ind. Mine Foreman.

Letter No. 4—The letter of A. A. Allen, on this subject, *Coal Age,* Feb. 13, p. 331, has struck a vital point, and his remarks are what we can all indorse. The fact is generally conceded that the more intelligent a workman is, the better work he does. But, being intelligent makes the man sensitive and, being sensitive, he cannot endure all things.

The intelligent workman and the one who gives the most efficient service naturally abhors the living conditions to be found at the average coal-mining camp. The same is true, also, in respect to the working conditions to be found in many mines. The man's training has fitted him for more congenial surroundings and he will not stay where the social conditions are of a low order, such as exist in camps where church and school privileges are lacking, the houses poor and ill-kept, the streets and sidewalks in bad condition, and cows, hogs and chickens roam promiscuously about.

Too often it is the case that the houses provided for the men have been built by contract, are poorly constructed of cheap lumber, and have no water, lights or other conveniences. It may be that they are located in a swamp or on low ground or, perhaps, on a steep hillside where approach is difficult and there is no opportunity for the cultivation of the ground and the making of a garden.

Poor Working and Living Conditions Destroy the Ambition of Good Workers

Working conditions and living conditions are twin sisters, and are commonly on the same order. Practical business management has come to realize that the successful development of a large operation depends equally on satisfying the men in both of these respects. In my own humble opinion, it would seem a good plan to build houses for the different classes of labor that are always to be found in the mines. It can hardly be expected that all the workers in a mine will be of the same grade or class. All have not the same ambition and desires.

There are men who are constantly seeking advancement and promotion to higher positions in life, and there are others who have no such ambition but are content to live on the same low level. To give to all of these men the same privileges, and expect the man of high ambition to be satisfied with the dirt and filth of his less ambitious neighbors would be to lower his ideals if, in truth, he would consent to stay where he was not accorded the privileges he has the right to expect.

Again, if the man of low ideals, living down in some back alley, is provided with the same conveniences that are given to one of higher ambition, the latter will have no incentive to better himself, but will often be satisfied to let things take their own course and make no effort to improve his surroundings. On the other hand, as men are quick to observe a difference in the treatment accorded to another, the desire is at once aroused in the man first mentioned to secure the same privileges and accommodations for himself.

Effect of Rewarding Faithful Workers

For example, here is Joe who keeps his little shack clean and tidy. The superintendent of the mine has noted that fact and offers Joe another place to live, where he will have a better house and a good chance to make a garden, knowing that he will take care of it. He has observed, also, that Joe is a good worker and has passed the word to the mine foreman to give him a chance.

In this manner, it is possible to build up a good, industrious body of men by improving both their working and their living conditions. The good workman has usually a good helpmate in the home, one who would not be satisfied to live in dirt and filth; but if compelled to do so, it will not be long before her discontent will create the same feeling in the man and cause him to wish to seek another place.

The last few years have proved conclusively that labor is our greatest asset. A wise management naturally dreads to see a good man leave its employ; but looking at the situation from the worker's standpoint, we cannot deny that we would do the same thing ourselves if placed in his position. Let us hope that these conditions will be improved steadily in our mines.

Osceola Mills, Penn. S. D. Hainley.

INQUIRIES OF GENERAL INTEREST

ANSWERED BY JAMES T. BEARD

An Interesting Mine Haulage Proposition

We have under consideration a proposition to improve our haulage in the mine. At the present time, the distance from the working face, at the head of the face entry shown in the accompanying diagram, to the foot of the hoisting shaft, is practically 2½ miles.

The heavy broken line, *EFGBCD*, in the figure, represents the present main track or haulage road. It will appear that there is a slight upgrade from the working face to the point marked *A* in the sketch; but from that point out to the foot of the shaft there is a slight grade in favor of the loaded cars. These grades are indicated in the figure by the signs plus (+) and minus (—), the former meaning an upgrade and the latter a downgrade toward the shaft.

Two plans have been under consideration, the first being to utilize the track that still lies in the old entry

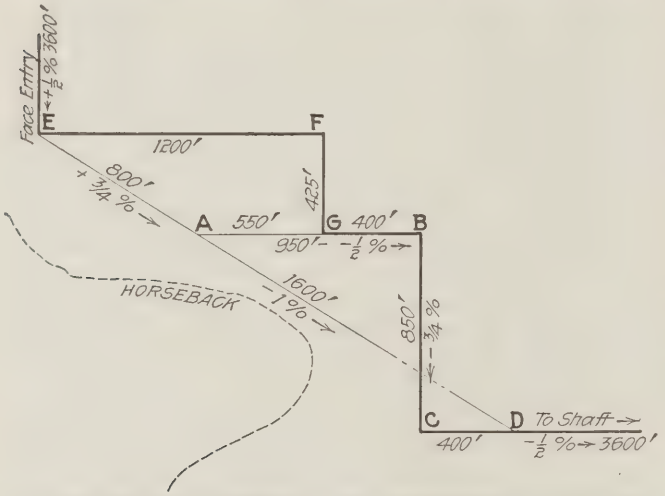

DIAGRAM OF PRESENT AND PROPOSED HAULAGE ROADS

from *A* to *B*, bringing the coal out by the route *EAB*, instead of *EFGB*, which would shorten the distance of haul 275 ft. By the second plan, the coal would be hauled out over a straight road *EAD*, instead of by the present route *EFGBCD*, which would shorten the haul 875 ft. between the points *E* and *D*.

As previously stated, track is already laid and in use from *A* to *G*, and on the main haulage road *EFGBCD*. The entry *EA* has been cut through and is ready for the permanent track; but the extension from *A* to *D* is not completed, a distance of 100 ft. still remaining to be cut through, as indicated by the dotted line where this entry crosses the main track *BC*. This portion being left had the advantage of not interfering with the circulation or disturbing conditions on the main haulage road until everything was complete to make the proposed change.

Moreover, there are two bad faults that must be cleaned up on this entry, before track can be laid and the road utilized for hauling coal. This work, together with the timbering of the entire entry from *E* to *D* will mean a considerable expense, in addition to the necessary outlay for tracking and ties, all of which must be taken into consideration in determining the practicability of making this change at the present stage of development of the mine.

It is estimated that we have some two million tons of coal in sight. We are using electric haulage, the present capacity of the motors being 24 trips a day, hauling 50 tons in a trip and producing a daily output of 1200 tons of coal. The haulage road is now double-tracked from *B* to *C* and thence out to the shaft. There is some double track also inside of *E*, on the face entry. The proposed road *EAD* would have but a single track. There is some double track also inside of *E*, on the face entry. Referring to the first proposition, the cost of fixing up the *ABCD*, for permanent haulage, may be considered as equal to the expense of laying track from *A* to *D*.

The question that we are at present considering is, Will the future life of this mine justify making the proposed change in the main haulage road? It is a problem on which we have been figuring for some time. In fact, as will appear from the work already accomplished, the plan had been practically adopted once and the work started and then abandoned for a time, till better conditions should prevail in the coal-mining industry.

We believe that many of the practical readers of *Coal Age* can outline, in a general way, to what extent the saving effected by the proposed change would justify the outlay for that purpose. Suggestions along this line will be greatly appreciated. J. H. DICKERSON.

Cambridge, Ohio.

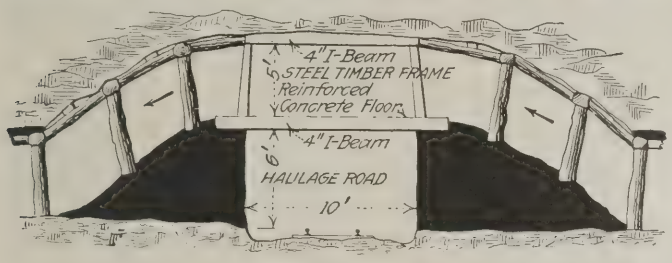
We gladly submit this proposition to our practical readers, inasmuch as it presents an opportunity not only for a fair explanation of the work required, but also for the display of good practical judgment in regard to the requirements in underground haulage, in the development of a large mine.

While our correspondent has not stated the thickness of the coal or the height of the entries on the haulage roads, it may be assumed that this is a good workable seam of coal and overlaid with a generally good roof that has made possible the use of a considerable length of double track, on the present haulage roads.

The fact that there are two bad falls that must be cleaned up on the extension *AD*, which was driven some time since and allowed to stand, may be attributed to faulty roof conditions in proximity to the horseback indicated by the dotted outline in the figure.

The proposition is one that will often arise in the operation of coal mines, and we hope that it will receive the attention that it should demand. The systematic estimation of the probable costs, while they may vary from the actual expenditure for labor and material, cannot fail to be of deep interest to all who have similar problems with which to contend.

EXAMINATION QUESTIONS



ANSWERED BY JAMES T. BEARD

British Columbia Examination First Class, Nov. 20, 1918

(Selected Questions)

Ques.—Give a sketch of what you consider a good overcast; such sketch to show dimensions and other details sufficiently complete to construct the same.

Ans.—In the accompanying figure, is shown an overcast conducting an air current across a 10-ft. haulage road in a 6-ft. seam of coal. This overcast is constructed by blowing down the roof over the haulage road, to a height sufficient to give a sectional area above the floor of the air-bridge equal to the sectional area of the air-course. An uprise is then driven from the air-course to connect with this excavation in the roof

AN ECONOMICAL AND WELL BUILT OVERCAST

above the haulage road. A similar connection is made with the cross-entry air-course, on the opposite side of the haulage road, as shown in the figure.

A reinforced concrete floor or bridge is then constructed by spanning the haulage road with two 4-in. I-beams, one at each side of the excavation in the roof. These I-beams are given a good foundation on the top of the coal forming the ribs of the haulage road. Crossbars of steel rails are laid at intervals and supported between the two I-beams. When this framework is in place, a temporary board bottom is constructed and a solid floor of concrete laid to a depth of 6 in., embracing the cross-rails and forming a solid joint with the I-beams on either side and the rock wall of the excavation that now forms the rib of the overcast.

Care must be taken to make everything air-tight between the haulage road and the overcast, to prevent the leakage of air into the roadway. The connecting drifts on either side of the air-bridge are securely timbered and braced, as shown in the figure, after setting the steel timber frame above the haulage road, as indicated, for the support of the roof above the air-bridge.

Ques.—A current of 140,000 cu.ft. of air is delivered at the foot of a downcast shaft and there divided into three splits as follows: Split A, 6 x 7 ft., 5000 ft. long; Split B, 6 x 6 ft., 4500 ft. long; Split C, 6 x 5 ft., 4000 ft. long. What quantity of air will pass through each airway?

Ans.—The first step in finding the natural division of the air current between these three splits is to calculate the potential factor for each split. Thus, reducing each factor to its lowest terms,

$$A, \quad a\sqrt{\frac{a}{lo}} = 42\sqrt{\frac{42}{5000\times 26}} \qquad 7\sqrt{\frac{7}{10\times 13}} = 1.624$$

$$B, \quad = 36\sqrt{\frac{36}{4500\times 24}} \qquad 6\sqrt{\frac{6}{9\times 12}} = 1.414$$

$$C, \quad = 30\sqrt{\frac{30}{4000\times 22}} \qquad 5\sqrt{\frac{5}{8\times 11}} = 1.192$$

$$\text{Sum of potentials} \quad . \quad . \quad . \quad 4.230$$

In finding the natural division of air, the work is much simplified by taking the lowest values for the area, length and perimeter, by striking out common factors in each of these. For example, in the above three splits, the sectional areas, 42, 36, 30, have a common factor 6, which divided out gives for the relative areas, 7, 6, 5. In like manner, the lengths 5000, 4500, 4000, are reduced to 10, 9, 8; and the perimeters 26, 24, 22 become 13, 12, 11. These relative values are then used to calculate the relative potential factors, as shown on the right, above.

The quantity of air passing in each split is then proportional to the relative potential for that split, and we have

$$A, \quad q_a = \frac{1.624}{4.23}\times 140{,}000 = 53{,}750 \text{ cu. ft. per min.}$$

$$B, \quad q_b = \frac{1.414}{4.23}\times 140.000 = 46{,}800 \text{ cu. ft. per min.}$$

$$C, \quad q_c = \frac{1.192}{4.23}\times 140{,}000 = 39{,}450 \text{ cu. ft. per min.}$$

$$\text{Total} \quad . \quad . \quad . \quad 140.000 \text{ cu. ft. per min.}$$

Ques.—If 65,000 cu.ft. of air per min. passes through an airway 7 x 7 ft., with a water gage 1.5 in., what quantity of air will pass through another airway of the same length, 8 x 8 ft. in section, the pressure remaining the same?

Ans.—In this case, the length of the airway and the pressure per square foot being the same, the quantity of air circulating in each is proportional to the potential factor $a\sqrt{\frac{a}{o}}$. For the first airway $a = 7\times 7 =$ 49 sp.ft.; $o = 4\times 7 = 28$ ft. For the second airway, $a = 8\times 8 = 64$ sq.ft.; $o = 4\times 8 = 32$ ft. The potential factors for these two airways are therefore,

$$\text{Airway } 7\times 7, \qquad 49\sqrt{\frac{49}{28}} = 49\sqrt{1.75} = 64.82$$

$$\text{Airway } 8\times 8, \qquad 64\sqrt{\frac{64}{32}} = 64\sqrt{2} = 91.51$$

Finally, for the same pressure, the quantity passing being proportional to the potential, the quantity ratio is equal to the potential ratio, and we have

$$\frac{x}{65{,}000} = \frac{91.51}{64.82} = 1.396$$

$$x = 65{,}000\times 1.396 = 90.740 \text{ cu. ft. per min.}$$

FOREIGN MARKETS AND EXPORT NEWS

Latest Developments in the Export Coal Situation

New Department Created by Shipping Board Will Handle Question of Vessels—Every Effort Being Made to Expedite Matters So That America's Foreign Coal Trade May Become a Reality

Ships are available to carry American coal abroad. This is the most important development when the frenzied discussion of the export situation, which has been in progress for ten days, is summed up. The Shipping Board has created a department of coal exports. Through this new department it expects to do all in its power to facilitate the exportation of American coal. In order that its coöperation may be of the most intelligent kind, the Shipping Board called a meeting of representatives of producers, exporters and brokers. The meeting was held May 29 and resulted in an all-day discussion of the export situation.

It is not the intention of the Shipping Board to allocate a certain amount of tonnage to the coal industry at this time, but it is expected that a business-like handling of coal exports will allow this country to get into the world's coal trade in an important way and at the same time to furnish outbound cargoes for shipping which must be dispatched to bring back cargoes from other countries. The meeting developed the fact that the chief obstacles to be overcome are by no means insurmountable, and it was decided that the Shipping Board would send out a questionnaire at the earliest possible moment so as to secure in orderly fashion the consensus of opinion on disputed questions and in order to furnish the Shipping Board with a more definite idea of the number of operators who are willing to enter the export trade.

In announcing the creation of its department of coal exports, the Shipping Board issued the following statement:

Statement of Shipping Board

"The Shipping Board is greatly interested in developing American coal exports, but as so much of our tonnage had to be devoted to food relief service we have not had the necessary ships to adequately serve the trade. Happily, the time has now come when we can plan in a constructive way for the development of our coal exports, and, recognizing the importance of this work, and in order to carry it forward, the Board has authorized the creation of a new department of the Division of Operations, to be known as the Department of Coal Exports.

"After a very careful canvass of the field for a man with the necessary qualifications and at the same time unbiased by any connection with the industry itself, we have selected H. Y. Saint, formerly Director of the Foreign Trade Bureau of the Seattle Chamber of Commerce, to take charge of the new department.

"The Department of Commerce, the Fuel Administration and the Foreign and Domestic Trade Bureau of the State Department have been requested to coöperate with the new Department of Coal Exports."

That the National Coal Association is impressed by the action taken by the Shipping Board is shown by the following statement made by J. D. A. Morrow, who is in active charge of the Association:

"Opening foreign markets to the American coal trade, as contemplated by the Government in the creation of the new Department of Coal Exports, announced by the Shipping Board, will provide the industry, it is believed by representative operators, with a new and powerful stimulant which should quicken production toward the pace that must be maintained if a serious shortage in home markets is to be averted next fall and winter.

"For months the coal industry of the United States has been unable to supply even a small percentage of the millions of tons of coal needed in foreign markets. This has been entirely due to the shipping situation, the first call on ships being for the homeward transportation of troops and the outward flow of foodstuffs to Europe. In the meantime, while almost every nation under the sun has been calling for coal, American mines have been producing from one-third to one-half their full-time output—in some fields, even less.

"The situation has now been reached where there must be a decided increase in production if our own needs are to be met in this country. That increase can be effected only by the entrance of buyers into the market. Mine forces cannot be kept together and mines cannot operate if there are not orders to fill. American buyers have not been in the market during the past few months to the extent necessary to enable operators to do more than keep their forces together. The men are going and have gone, in many instances, into more regular and less hazardous employment. Also thousands of miners are today at Atlantic ports, awaiting passage to Europe.

Coal Exports Would Stimulate Mining

"The entrance, therefore, of foreign buyers into American coal markets should help in keeping together forces necessary to produce coal to meet not only foreign requirements, but needs in the United States next fall and winter.

"Unless the United States can ship its coal abroad there is every indication that there will be a world-wide shortage of coal next winter. No other country can supply the demand. In Great Britain production has dropped to levels far below the pre-war days. It is regarded as virtually impossible that Great Britain can mine the coal that the world will need. She is not producing it in sufficient quantities now, and the rationing system, under which consumers may obtain only a limited supply, will be continued, it has been announced, in the United Kingdom for months to come, notwithstanding the fact that hostilities ceased more than seven months ago.

"The coal mines of France will not produce their pre-war output for from three to six years, engineers estimate, while in Russia the situation, so far as next fall and winter are concerned, is regarded almost as hopeless. Wholesale bankruptcy threatens the coal industry in Germany—indeed, in many instances has already overtaken it—as the result of revolutionary changes in governmental policy affecting the industry and because of general labor disturbances. A shortage characterized as acute exists in Australia, the one remaining large source of supply. Only in Spain, which does not produce enough to meet its own needs, has coal production been on the increase during the year, and in Italy, where a small quantity of lignite, far from sufficient to meet Italian needs, is mined.

Whole World Looks to America

"The entire world, with the exception of the United States, is in the throes of a universal coal shortage today and only the most sweeping increase in production wherever coal is mined can avert world-wide suffering next winter. More than one hundred million tons of coal could be sent out from the United States during the remainder of the year, were there ships enough to carry it, without meeting in full the foreign demand."

It is very clear, from the discussion at the Shipping Board meeting, that practically all those contemplating exports favor the adoption of the Welsh charter. The variations from that charter, which have been used by the Shipping Board, were said to cause much confusion and to work against the interests of the American shipper. Not much enthusiasm for Government inspection of coal was evidenced. Some of the advantages of such a plan were recognized, but it was declared that responsible exporters will keep up the quality of their coal and that the situation is one which will handle itself. The advantage of having an analysis of the coal accompanying the invoice was admitted generally.

There was a tendency on the part of small shippers to fear that they would have difficulty in securing equal rights with larger exporters, but they apparently are willing to put themselves in the hands of the Shipping Board.

All agree that a much more satisfactory condition has been brought about by concentrating in the one office all matters pertaining to coal exports. Mr. Saint, who is in charge of the coal department of the Shipping Board, was born and reared in western Pennsylvania and has a knowledge of the problems surrounding production. His experience on the Pacific Coast has been with foreign trade. These advantages, as well as his capacity as a businessman, recommended him to the Shipping Board for the place.

Mr. Saint has appointed a committee to inquire into the demand of insurance companies that shifting boards be used in loading bituminous coal. Such a requirement, it was pointed out at the meeting, would add $2000 or more to the cost of loading each ship.

Netherlands Coal Supply

Trade Commissioner Arthur H. Redfield reports from The Hague under date of Apr. 18, 1919, that the Netherlands Coal Distribution Office (Rijks-kolendistributie) has recently given out figures of the production and importation of coal, lignite and peat for the years ending Mar. 31, 1916, to 1919, which have been allotted by that office. As peat was first included in the distribution system at the end of April, 1917, no exact statistics of its shipments are to be had before that date, and the figures given below for 1916 and the first months of 1917 are based upon an estimate. The shipments of peat and lignite, moreover, are given in terms of their fuel equivalent in coal. The amounts stated are in metric tons and are for the year ending March 31.

Countries	Years Ending Mar. 31 1917, Metric Tons	1918, Metric Tons	1919, Metric Tons
Imported from Germany	3,377,533	2,761,110	735,100
Imported from England	1,295,722	201,012	92,376
Imported from Belgium	619,439	169,877	84'491
Imported from United States	.....	.....	84,491
Total imports of coal, coke and briquets	5,292,694	3,131,999	947,647
Shipments of coal from Limburg	2,553,577	2,980,318	3,210,149
Shipments of peat*	400,000	450,000	650,000
Shipments of lignite*	.....	46,053	526,886
Total domestic coal, peat and lignite	2,953,577	3,476,371	4,387,035
Grand total	8,246,271	6.608,370	5,334,682

* Converted to fuel equivalent in coal.

The figures in the table regarding the Limburg mines differ from the ordinary published figures, in that the figures for shipment are given instead of the total production of the mines, from which must be subtracted the coal consumption at the mines. In the period from Apr. 1, 1918, to Mar. 31, 1919, as compared with the corresponding period of 1917-18, a greater quantity of domestic fuel was available,

amounting to over 900,000 tons of coal, while over 2,000,000 metric tons less coal was imported from foreign countries. As compared with the year 1916-17, there were in the year 1918-19 almost 1,500,000 metric tons more available from domestic production and 4,400,000 tons less were imported from abroad.

Lancashire Coal Export Trade

In the course of an interesting article dealing with the Lancashire coal trade the "Statist" says that Lancashire is the fourth of the coal-producing counties in the United Kingdom, and in 1917 its output amounted to 21,760,000 tons, compared with 40,875,000 tons in Yorkshire, 32,133,000 tons in Glamorgan and 30,843,000 tons in Durham. The bulk of the coal raised is used locally for industrial and domestic purposes, but the export trade is considerable, especially in bunkers. A large coastwise traffic is also done to Ireland and the Isle of Man.

The trade has, for special reasons, not suffered material detriment during the war. The bulk of the coal shipped from England comes, in normal times, from the Bristol Channel and from the northeastern ports, both Welsh and Yorkshire coals being of the highest quality and easily standing transportation. The Admiralty commandeered a large proportion of the output of these districts, especially of the best coals, and Cardiff, Newport and Swansea, as well as Newcastle and Hull, were too busy meeting the requirements of the English and Allied navies to fill civilian needs. Only second-grade steam coal was available for export, and even this was often replaced by inferior qualities.

Users Like Lancashire Coal

Many foreign and home consumers turned to Lancashire coal, and, it is reported, were favorably impressed by its calorific power and by its adaptability for many purposes. Bituminous coal is naturally more easy to light and burns with a characteristic flame which is altogether absent from anthracite, but in heating capacity it is generally inferior. Both on sea and land, the Lancashire product has been extensively used during the war in steam-raising plants which formerly used only Welsh or Yorkshire coals, and, though results naturally varied with the type of boiler and with the arrangements for draft, the general verdict was one of surprised satisfaction.

It is probable, in the circumstances, that the new clientele attracted to Lancashire coal for the want of better will remain permanently with it. A practice, common in the United States, of purchasing coal for analysis, is coming increasingly into vogue in England, and the practice will benefit Lancashire coal, which, though showing a good return in calories and a low percentage of ash, has not the reputation attaching to the famous seams of Yorkshire and South Wales.

At present foreign importers are not inclined to haggle about prices, and therefore the problem of restoring England's export trade in coal hinges solely on output. In the absence of any calamitous social or industrial developments, output should rise above the war standard with the demobilization of able bodied miners and the execution of long overdue repairs, renewals, and improvements to mechanical equipment. The ultimate effect of the reduced hours on output is too problematical to discuss, but in Lancashire the best opinion views the matter in a very hopeful light.

British Coal Output Decreasing

The output in the United Kingdom had been decreasing long before the war. The average per underground worker which in 1905 was 360 tons, had fallen in 1913 to 321 tons, but it is expected that its downward course will now be stayed through better working methods and through the exercise of good will on the part of miners. Most of Great Britain's rich shallow seams have been exhausted, and the raising of coal from thin seams at great depths necessarily involves increased expense.

The rapid decentralization of industry in the last 50 years, and the more even distribution of manufactures over the world, naturally caused a slackening in the rate of industrial development in Great Britain, and her coal exports did not increase comparably with those of other countries. To prevent unemployment on a large scale, it is advocated that English exports be resumed as soon as possible, free from official interference. Her railways, docks and ships derive profit from the trade, which also enables her to import more cheaply her requirements of food and raw materials. Further, English coal is needed in foreign coaling stations for the use of British steamers, and many of her outward-bound ships can, by securing a coal cargo, avoid a profitless journey in ballast.

The complete resumption of coal exports by Great Britain is conditioned by the supply of shipping, but, according as it is provided, it is expected in Lancashire to stiffen prices in the home market. Foreign wants are imperious and must be satisfied, and, moreover, Germany, England's principal competitor before the war, is for a time out of the market. At present under the control system Lancashire coal for export is on an average from 6s. to 8s. per ton dearer than for home consumption, and naturally merchants prefer to ship, but are hindered by the embargo. When shipments no longer require a license, prices will probably rise to the present export level. The increased demand from abroad may result in the taking on of extra hands in the Lancashire mines, where employment is already given to nearly 100,000 workers.

The proposed scheme of state electric-power stations, if carried out, should effect considerable economies in the use of coal for industrial purposes in the cotton and steel manufacturing areas of Lancashire, but such an eventuality is at present too remote to use as a calculable factor in the plans of coal owners. Besides, increased demand in other directions, due to the growth of population and similar causes, will offset a decrease in the quantity of coal used for steam-raising or gas-making purposes. Of more immediate concern to Lancashire and to the coal-mining industry of the United Kingdom in general are the findings of the Coal Commission as to nationalization and the proposals formulated by the Coal Controller as to mining finances, both of which will to a large extent determine not only the fate of the coal trade but the industrial future of the United Kingdom.

Foreign Coal Trade Opportunity

A firm in Malta is proposing the opening of an American shipping and coaling department, and desires to communicate with steamship owners and coal-mining companies. References. Further details may be obtained by writing to the Bureau of Foreign and Domestic Commerce, Washington, D. C., or any of its branches, and referring to File No. 20,490.

Coal Traffic in Spanish Ports

The ports of Vigo, Corunna and Ferrol in northwestern Spain are important depositories for coal supplied to the various steamships calling at these ports, states Consul Edward I. Nathan, Vigo, under date of Mar. 27, 1919. In prewar times this coal was principally imported from Wales and deposited either ashore or in floating hulks, of which there are three in Vigo. Such deposits can be made in bond, but this privilege is accorded only to Spanish concerns. Hence a British company which supplies coal at Spanish ports does so through a subsidiary Spanish corporation, and a similar course would have to be adopted by American concerns seeking this trade.

Over 50,000 tons of Welsh coal were imported at Vigo in 1913. Of this amount 37,770 tons were imported by two firms alone. About 8000 tons of briquet coal were also imported in 1913. Coal continued to be imported at Vigo during the years 1914 to 1916 in greatly reduced quantities. None was imported in 1917 and 1918, but with the renewal of foreign steamship service such imports are being resumed.

Spanish coal of inferior quality from the mines in Asturias is used locally by the railroads, gas works and for coasting steamers. In 1913, 16,318 tons of this coal were brought to Vigo by steamers and in 1918 10,780 tons were brought. A small quantity also comes by railroad. Spanish coal now sells at 180 pesetas (the normal value of the peseta is $0.193), or $34.75 per metric ton. Welsh coal has recently been sold as high as $40.50 per ton.

Vice Consul W. Bruce Wallace, at Corunna, reports as follows: Coal has for a number of years been one of the most important items of import at Corunna, averaging 14,000 metric tons until 1913, when the imports increased to 35,234 metric tons, and to 58,426 in 1914. The imports were all from Great Britain and were principally Welsh steam coal for bunkering, although there were also important sales to the Spanish railroads. The imports decreased on account of the war and were only 6700 metric tons in 1916 and 1460 tons in 1917. Imports of Welsh coal at the neighboring port of Ferrol amounted to 7075 metric tons in 1913.

In prewar times Welsh coal could be imported at Corunna c. i. f. at $4.83 per long ton, but this price increased enormously during the war, and although prices have decreased since the armistice a good quality of Welsh coal costs $33.78 per long ton c. i. f. Corunna at the present time. The average freights were $1.06 per long ton before the war, but are at present $15.05 per long ton. It has hitherto been impossible to import American coal owing to the high cost of the freight.

[A list of importers of coal in northwestern Spain can be obtained from the Bureau of Foreign and Domestic Commerce or its district or coöperative offices by referring to file No. 116007.]

Imports of Coal Into Denmark

According to an excerpt from *Finanstidende*, Copenhagen, Mar. 5, 1919, transmitted by Commercial Attaché Erwin W. Thompson, the armistice gave Denmark hopes of larger imports. With regard to coal, however, the development has been different, because of the difficulties due to the revolution in Germany and the English mining strikes. The combined import of coal, coke, cinders and briquets to Denmark was as follows: In 1913, 3,573,000 metric tons; 1914, 3,612,000 tons; 1915, 3,890,000 tons; 1916, 3,704,000 tons; 1917, 2,165,468 tons; and in 1918, 2,242,124 tons.

From the summer of 1917 until the armistice was declared the coal imports were about 200,000 tons per month, whereas the average in 1913 was nearer 300,000 tons. On account of the German revolution, however, this was reduced to about half during the last two months of 1918. In January the imports were about 160,000 tons, 40,000 tons of which were German coal, by special agreement; but at present the imports from Germany may be considered as practically stopped, except for 16,000 tons of gas coke per month. At the same time the imports

from England have increased somewhat, but even if they amount to 200,000 tons a month, which is considered the maximum, the quantity would be no higher than the average during the last war years. This is quite insufficient at a time when the Danish industrial demands are so great.

Whether Denmark can get coal from countries other than Great Britain depends upon America's willingness to supply the European market with fuel. Already the Swedish State railways have bought 30,000 tons of American coal for delivery in Goteborg inside of a few weeks, and it is rumored that the Dutch Government has closed for 50,000 tons to be shipped to Rotterdam. The offers of American coal to Denmark are also lively. Export license has already been secured for 500,000 tons at prices which are about the same as for British coal—that is, $30 c. i. f. Danish port. This low price is probably due to the fact that coal can be brought in ships engaged in the transportation of war material from France.

April Coal and Coke Exports

Exports of coal and coke, as reported by the Department of Commerce for April, 1919, and the figures for April, 1918, as finally revised, are as follows:

	April, 1918	April, 1919
Anthracite, tons	340,861	285,190
Bituminous, tons	1,554,501	811,128
Exported to:		
Italy	2,016	32,309
Canada	1,128,549	501,940
Panama	70,870	19,088
Mexico	12,675	6,200
Cuba	212,355	58,173
Other West Indies	28,063	31,302
Argentina	9,869	14,914
Brazil	25,097	70,333
Chile	None	4,847
Uruguay	6,107	None
Other countries	58,900	72,022
Coke	141,003	44,883

Bunker coal loaded on vessels in the foreign trade amounted to 682,592 tons in April, 1919. Imports of coal in April, 1919, totaled 60,550 tons, as compared with 91,334 tons in April, 1918. Practically all of the imports came from Canada.

Foreign Freight Rates

W. W. Battie & Co.'s coal trade freight report for the week ending May 26 states that a number of steamers were chartered to carry coals to ports in Brazil, Argentine Republic, West Indies and in Europe, all at the chartering executive's rates. Additional tonnage is also being offered for these destinations, at the chartering executive's rates, and although many shippers have endeavored to secure a reduction in these rates to South American and West Indian ports, they have not met with any success.

The chartering executive's rates are as follows:

Steam—Havana, $7.50, 600 tons dis.; Cardenas or Sagua, $9, 300 tons dis.; Cienfuegos, $9, 500 tons dis.; Caibarien, $9.50; 300 tons dis.; Guantanamo, $8.50, 500 tons dis.; $9, 400 tons dis.; Manzanillo, $9.50, 300 tons dis.; Bermuda, $9.50, and Bermuda, p. c. and dis. free, 300 tons dis.; Kingston, $9.50, 400 tons dis.; St. Thomas, $10, 500 tons dis.; St. Lucia, $11, 500 tons dis.; Santiago, $8.50, 500 tons dis.; $9, 400 tons dis.; Barbados, $11, 500 tons dis.; Port of Spain, Trinidad, $11, 500 tons dis.; Curacao, $10.50, free p. c. Curacao, 500 tons dis.; Rio, $19.50 net, 1000 tons dis.; Santos, $19.50 net, 1000 tons dis., or $21 net, 600 tons dis.; Buenos Aires or La Plata, $18.50 net, 1000 tons dis.; Montevideo, $19.50 net, 750 tons dis.; Pernambuco, $18.50 net, 500 tons dis.; Bahia, $18.50 net; Bahia Blanca, $20, 1000 tons dis.; To Nitrate Range, $16.50 gross, prepaid.

Sail (maximum)—Para, $15.50 net; Bahia, $18.50 net; Pernambuco, $18.50 net; Rio, $19.50 net; Santos, $19.50 net; Rio Grande do Sul, $20.50 net, 400 tons dis.; Buenos Aires, $18.50 net; La Plata, $18.50 net; Montevideo, $19.50 net. To Nitrate Range, $16.50 gross, prepaid.

South Wales Coal Shipments

During the month of April the total coal shipments to foreign destinations from South Wales ports amounted to 1,551,157 tons of a declared value of £2,674,914. Out of this quantity Cardiff (including Barry and Penarth) shipped 925,936 tons of a value of £1,607,200, the composition of the coal being 564,057 tons of large, 294,567 tons of smalls and 67,312 tons of through and through. Newport exported 212,179 tons of large, 112,860 tons of small and 9364 tons of through and through—a total of 334,403 tons of a value of £557,166. Port Talbot shipped 101,670 tons of a value of £164,081; and Swansea 189,148 tons of a value of £346,467.

The coastwise shipments in April last were as follows: Cardiff, 36,399 tons; Newport, 47,600 tons; Port Talbot, 4599 tons; and Swansea, 8676 tons—a total of 97,274 tons. In addition 11,629 tons of coke of a value of £31,472 were exported. These shipments do not include the coals cleared on Admiralty account. The quantity of patent fuel shipped coastwise was as follows: Cardiff, 37,120 tons; Newport, 6955 tons; Swansea, 75,042 tons; and Port Talbot, 16,473 tons—a total of 135,590 tons of a value of £269,809.

The quantity of bunker coals shipped for the use of steamers engaged in the foreign trade during April amounted to: Cardiff, 163,332 tons; Newport, 54,447 tons; Swansea, 24,544 tons; Port Talbot, 12,442 tons; and Llanelly, 895 tons—a total of 255,660 tons.—Journal of Commerce.

German Coal Situation

The coal producers of Germany are complaining that the advances of wages to the miners and the increasing demands of the latter for more wages and shorter hours are seriously injuring the coal industry of the country. The Berlin Chamber of Commerce has submitted to the German Government a memorandum showing the serious injury inflicted on the German coal industry in consequence of the exorbitant demands for higher pay made by the workmen and the officials. The situation is summed up by the Chamber of Commerce as follows:

In Upper Silesia hewers were paid in peace times 9 marks for a nine-hour shift. During the war these wages rose to 13 marks per shift, while the everage output declined from about 1¼ tons to three-quarters of a ton. At the beginning of November the miners demanded and received 18½ marks per shift. Simultaneously with this advance, the average production declined fractionally again. As a result, the cost per ton for the hewers' wages alone is now 24½ marks, as against 7½ marks in pre-war days.

In order to meet this increased cost the coal syndicate owners raised the price of coal 10 marks on Jan. 1, 1919. If to this be added 20 per cent. Government tax on the price of coal, the additional burden placed on German industries by this advance in wages will amount to 3,000,000,000 marks, assuming that the total production of coal in Germany to reach 250,000,000 tons per annum. This sum is 2½ times as much as was expended annually upon the German army and navy prior to the war.

The great increase in coal prices will have a very serious effect upon production costs in the iron and steel industries. Pig iron, which formerly cost 60 marks a ton, cannot now be made for less than 248 marks per ton. It is impossible to estimate all the consequences of this agitation for higher wages, but the competitive capabilities of German industry in the world will be seriously affected by it. As wages in other countries, which are abundantly supplied with cheap raw materials, are far behind the German rates, it will be impossible for the impoverished empire to regain anything like its former prosperity unless the workmen decrease their demands and increase their average output.

Coal and Coke Exports from New York in April

Shipments of coal and coke to foreign countries from the Port of New York during April of this year show a falling off from the shipments for the corresponding month in the two previous years. There was a considerable falling off in shipments of anthracite to Canada in April of this year as compared with the same month in 1917 and 1918, owing no doubt to the lack of bottoms or at least to the high freight rate asked. But three countries received bituminous coal through the Port of New York during April and the tonnage was more than 2000 tons less than was shipped during April of last year, while the average price per ton was 59c. less.

Coke shipments also show a decrease as compared with shipments in previous years, 468 tons having been exported as compared with 633 tons in April of 1918 and 1325 tons in April of the previous year. Comparing the average cost per ton shows than in April of this year it was exactly $10 less than it was in April of last year, but nearly $3 higher than in April of 1917.

Shipments of anthracite, bituminous and coke, compared with the same month in 1917 and 1918, are shown in the following tabulation.

	Anthracite						Bituminous						Coke					
	1917		1918		1919		1917		1918		1919		1917		1918		1919

COAL AND COKE NEWS

Harrisburg, Penn.

On May 28 the administration compensation bill was re-reported to the Senate judiciary special committee practically as drawn by Attorney General Schaeffer. The committee has not accepted any of the amendments demanded in the measure by Joseph Grundy. Any amendments that are made in the bill will follow hearings on the house side of the Legislature. No changes are now contemplated except such as are calculated to strengthen sections that may not be clear as to their intent. The general principle of an increase in the basis of compensation from 50 to 60 per cent. of the weekly wage, with $20 as the legal maximum and a minimum payment of $6 a week will be adhered to.

The bill reorganizing the compensation board has been reported from committee. This bill raises salaries and makes the board a purely judicial body, all its administrative features being taken away.

The Senate passed the rehabilitation bill. The measure now goes to the House. The bill creates a department of rehabilitation in the department of labor and industry that will be charged with the duty of providing for the rehabilitation of workers injured in the industries and coal mines as well as for the rehabilitation of congenital cripples.

On May 28, a committee of senators was appointed to confer with anthracite coal operators in an effort to solve the mine cave question. Senator Max Leslie, of Pittsburgh, chairman of the sub-committee, states that he will endeavor to have the present voluntary agreement with the coal companies in the Scranton region greatly broadened.

For nearly the entire session Senator Davis, of Lackawanna, has been fighting to have his two bills reported out of committee with an affirmative recommendation. Some members favor reporting out the second bill of the Senate or calling for the appointment of a Pennsylvania Anthracite Mine Cave Commission.

With the exception of Senator Davis, the members of the committee were against reporting out the first Davis bill, all expressing the opinion that it would not remedy conditions, and to put a man in jail would not repair damaged property, etc.

Charleston, W. Va.

Developments during the week ended May 24 in the West Virginia coal fields demonstrated that coal was in far greater demand and that it was only a question of time until it would be difficult to secure all the fuel needed in various markets. While production had not reached its limit yet the average output of the state was from 66⅔ to 75 per cent., and in some instances was even higher. In every market to which West Virginia coal goes there was a lively demand. That applied to tidewater, to general eastern and western markets, and to the Lakes in particular. The volume of lake business up until the latter part of May had been steadily growing.

Market conditions have improved to such an extent and the demand for coal is such that a number of West Virginia producers have disposed of their entire output for some time to come. That is particularly true as to the producers of smokeless coal in the New River and Pocahontas regions. Many of them no longer have any coal to sell. Their output is sold. These smokeless coals are now quoted at $3 a ton.

Regions producing these coals are rapidly reaching full production. Though not yet operating on a full time basis, preparations are being made to work up to full time capacity as soon as labor conditions improve. Scarcity of cars may also prevent getting capacity product to market.

The trend of development in the Pocahontas district may be seen in a rapid reduction in the no-market losses from 88,000 to 64,000 tons—a gain of 24,000 tons. A total of 25,000 tons has been cut off the total production losses, which were reduced from 114,000 to 88,000 tons; production mounted from 285,000 to 289,000 tons. Production is now approximately 66⅔ of capacity. The labor shortage is gradually entailing heavier losses, now being 18,000 tons—an increase of 2000 tons. There was also a 100 per cent. increase in the car shortage loss.

While the market for coal is much improved there is little or no demand for coke, the production being only a little over 8000 tons. Prices are firm, with run-of-mine smokeless quoted at about $3 a ton.

Production in the Kanawha region has been further stimulated by more numerous orders from the Lake areas, though at the same time there is a large tonnage movement to general western markets. Some Kanawha producers are sold up to capacity for some time to come, though not all mines in the district are in operation; mines working operate from four to six days a week. On May 27 production was twice as large as it was on May 1. The output of the district as a whole has now reached about 70 per cent. of normal. Prices are stiffening quite materially.

Conditions in the Logan district were featured chiefly by a car shortage entailing a loss of 56,000 tons; the total production loss jumped from 127,000 to 175,000 tons. The output dropped from 176,000 to 164,000 tons, a loss of about 10 per cent. Last year's production during the same weekly period was 214,000 tons. Figures show a larger demand for Logan coal, no markets costing a loss of only 28 per cent. of full time capacity.

Fairmont, W. Va.

There continues to be a growth in the tonnage of coal mined from northern West Virginia coal fields in response to a much increased demand from all quarters, the total number of cars loaded during the week ended May 24 being in the neighborhood of 4600. Should loadings continue at the same rate until the end of the month, it will mean a total of about 18,000 cars for the month, or 4000 and perhaps 5000 cars more than for April; so it is safe to estimate a production of about 66⅔ per cent. in the northern West Virginia fields. As a result of such conditions idle mines are dwindling in number. Mines heretofore idle are not only now supplying the Lake trade but the export trade as well, and other western consuming areas are also absorbing more coals. However, Lake shipments are exceeding shipments to Chicago and other general western markets. So far the proportion of eastbound is much larger than westbound coal, shipments of railroad fuel swelling the volume of eastern shipments. Some of this coal, however, has been sold at extremely low prices. That a car shortage is impending is the belief of many shippers in northern West Virginia, although few if any operations have so far failed to receive an adequate supply. But only about half as many cars are coming into the district as was heretofore the case.

Louisville, Ky.

Louisville and western Kentucky coal operators, after a long and hard fight, have finally secured justice in connection with discriminatory rates on western Kentucky coals which made it impossible to compete in markets north of the Ohio River and also in Mississippi Valley and southwestern markets. The Ohio Valley Coal Operators' Association has been fighting the rate issue for many months. On May 21 this association secured the order of the Interstate Commerce Commission which directed the railroads to make marked reductions in rates on coal from the district (effective Sept. 1, 1919) to the Mississippi Valley, southwestern territory, Illinois and various northern and western states. The association assailed certain rates as being unjust, naming the Illinois Central and nearly a hundred other lines as instances. The commission held that many of the rates were unduly prejudicial as compared with rates to competing points, although not unduly high.

This will enable the western Kentucky operators to enter the general markets with a much better chance of securing profitable business. Due to the low prices on western Kentucky coals and unreasonable freight rates, it has been impossible to mine coal profitably and market it in many sections, especially north of the Ohio and in the far South. The result has been that western Kentucky operations, except where deliveries have been made by barge, have been held to a rather small field.

Alberta, Canada

Some minor changes were made in the Mines Act of the Province of Alberta at the session which recently came to a close. One amendment provides that the provisions of Section 29 of the act shall not apply to mines where coal is mined by removing all the overlying strata. This section also deals with the management of a mine, making it obligatory that its operations shall be under the "control and supervision" of a certificated manager; laying down rules and regulations to enforce the keeping of underground workings in such condition as will safeguard workmen. Another alteration provides for the semi-monthly payment of wages in coal mines as follows: "Wages earned from the 1st to the 15th day of each month shall be paid on the first Saturday after the 26th day of the same month, and all wages earned from the 16th day to the end of the month shall be paid on the first Saturday after the twelfth day of the following month; provided that if any of the Saturdays in question is a holiday the wages shall be paid on the Friday before." The power given an employer to retain money due for doctor's fees has been repealed. Safety lamps shall be inspected by a person holding a first, second or third class certificate. The two persons appointed by workmen to inspect a mine shall be practical miners.

PENNSYLVANIA

Anthracite

Lansford—The Hauto washery of the Lehigh Coal and Navigation Co., after being idle since the middle of February, resumed operations recently.

Pittston—The Kingston Coal Co., the Conlon Coal Co., the Haddock Mining Co., and the Lehigh & Wilkes-Barre Coal Co. are included in a list of Wyoming Valley employers who have made definite public announcement that former employes who went to war will be reinstated in their old jobs as fast as they return to claim them.

Scranton—The total production of anthracite by the Delaware & Hudson company in 1918 was 9,059,228 tons (long), an increase of 415,505 tons or 4.8 per cent. over 1917 shipments. The year's output was 11.8 per cent. of the total production of the anthracite mines and washeries. The number of breaker hours required for the company's production was 55,191.

Auburn—The South Mountain Coal Co., a new enterprise, has opened a washery at this place in Schuylkill County, where coal will be reclaimed from the Schuylkill River. The plant will have a daily capacity of about 600 tons and the output will be chiefly steam sizes. Capital was supplied by Hazleton and Philadelphia interests.

There are approximately 30 washeries, active and idle, on the Schuylkill River between Pottsville and Port Clinton, and a Pottsville authority says that there is about 50,000 tons of steam coal, for which there is a dull market at present, now stored at these plants.

Pottsville—Deeds recorded at the court house at this place recently show that a total of 3967 acres of anthracite coal lands changed hands. Four of the deeds recorded are from the Schuylkill Coal and Iron Co. to the Hudson Coal Co. The deeds in question include: A tract of 870 acres of land in Norwegian Township; 251 acres in Pottsville and Norwegian Township; 100 acres in Tremont and Tremont Township and 898 acres in Branch Township. Two other deeds recorded show transfer of coal lands to the Hudson Coal Co. as follows: One deed gives title to 529 acres Tremont

and Reilly townships; another deed transfers 1319 acres in Blythe and Schuylkill townships. A consideration of $10 was recorded in each case.

Bituminous

Latrobe—On the night of May 19 the barn of the Ridge Coal Co. near this place, burned to the ground. The barn was a 40 x 60 ft. structure. The loss is covered by insurance.

Washington—The Pittsburgh Coal Co. has purchased two tracts of coal land from William F. Ellwood, Susan E. Mounts and Agnes E. Brownlee, all of Washington, and E. E. Morris, of Waynesburg. One tract in Amwell Township contains 15.8 acres, and the other in Canton Township contains 108 acres. The price paid per acre was $300.

Waynesburg—An important sale of Greene County coal land took place here on May 13. Sheriff J. E. Adamson sold an undivided one-seventh interest owned by James R. Barnes, of Uniontown, in 126 tracts of coal in Center, Franklin, Washington and Morris townships. The interest aggregated 1500 acres. John W. Donnan, of Washington, Penn., was the purchaser of this interest for the sum of $252,000, or $168 an acre.

Pittsburgh—The Bureau of Mines has charge of the making of the moving picture of the coal industry recently authorized by the National Coal Association's board of directors. It is the desire of the bureau and of the association to receive any suggestions which members may care to make. Actual filming of the scenes probably will be begun late in June or early in July. It is intended to present the subject in some detail at meetings to be held in June in Pittsburgh, Chicago, Kansas City and Birmingham. The dates of the meetings are yet to be announced.

Uniontown—A tract of coal land in Springhill Township, Fayette County, appraised at $225,000 brought $40,000 at a Sheriff's sale recently. The tract of 311 acres was bought in by attorney Luke H. Frasher.

Directors of the Taylor Coal and Coke Co. held their annual meeting here recently. C. P. Bolton, of Cleveland, Ohio, resigned from the board of directors because of ill health. The following officers were elected: F. K. Moore, president; D. B. Stauft, secretary and general manager; F. H. Ulmar, treasurer; F. K. Moore, I. H. Elliott, H. A. Fuller, all of Cleveland and M. H. Bowman, of Uniontown, directors.

WEST VIRGINIA

Hartland—An expansion of operations having been decided upon by the Fellabaum Coal Co., it is not only arranging for further openings near this place but it is also building additional side-track to reach these mines.

Sterrett—The Main Island Creek Coal Co. shortly expects to be able to increase its coal production to the extent of 6000 tons a day, through the operation of the six new mines at this place. It is stated that shipments from all the plants of this company will soon aggregate 200 railroad cars a day, under normal conditions, when all the mines are in operation.

Beckley—Many improvements will be made at the various plants of the New River Coal Co., operating in Fayette and Raleigh counties, W. Va., during the summer, all with a view to securing a larger output. The company will probably build new tipples at Summerlee, Whipple and Lochgelly. The present capacity of the company's mines is about 12,000 tons a day.

Norton—The new Y. M. C. A. building erected by the West Virginia Coal and Coke Co. at this place was formally opened recently. General Manager E. Drennen made the presentation speech in turning the building over to the community, which is largely made up of employees of the company. The "Y" building and equipment cost $20,000, and is an expression of the company's interest in its employees. Charles D. Norton, of New York, the first vice-president of the company, was present.

Rainelle—The Chesapeake & Ohio Ry. has granted main line rates on coal to the Sewell Valley railroad coal operators.

The Sewell Valley line taps the holdings of The Meadow River Coal and Land Co., of Rainelle, Greenbrier County, W. Va., and the Gauley Coal Land Co., of Boston; these companies control about 200,000 acres of smokeless coal. Various analyses show it to run 73 to 75 per cent. fixed carbon and only 0.60 to 0.68 sulphur.

The Sewell Valley line connects north and west with the Kanawha & Michigan and the Coal and Coke railroad and to the northeastward with the Baltimore & Ohio.

Charleston—A new company which lately has begun to operate in the Coal River field is the Bradley Mining Co., having recently finished construction work on its plant.

Within a short time the Malleable Coal Co., of which Samuel Butler of Charleston is general manager, will construct about two miles of railroad to connect the company's plant with the Coal River branch of the Chesapeake & Ohio railroad.

Carter Brothers, of this place, are making progress in the construction of a mining plant at Shrewsbury, where coal will be mined from the Cedar Grove seam. This firm counts on beginning the shipment of coal within a short time.

OHIO

Columbus—The state of Ohio has under consideration the purchase of 7000 acres of coal land in Vinton County. The land is to be sold shortly at public auction.

The state is spending $600,000 a year for coal, of which $60,000 is for freight. If the mining were done by penitentiary labor, it is stated, most of the fuel expense could be saved, excepting the freight item, and it would be reduced. The land is said to be underlaid with an eight-foot seam of coal. Excellent shipping facilities would be provided by the Hocking Valley and the Baltimore & Ohio Southwestern.

Pomeroy—After a suspension of work for many months, all the Ebersbach mines—the Rolling Mill, Charter Oak, Forest Run, Dark Hollow and the big new mine at Syracuse—resumed operations May 13. It is expected that work will continue uninterruptedly during the rest of the year. The coal to be mined is for the Lake trade.

INDIANA

Evansville.—With the clearing away of the tipple, the old Ingle coal mine is a thing of the past. It was the first mine to be opened in Indiana and was owned by an English syndicate. When the shaft was sunk it was called the Bodiam mine, and eventually the workings extended under the Ohio River to the Kentucky shore. The last owner of this property was J. H. Moore, the proprietor of the Crescent coal mine in Evansville.

Indianapolis—Many companies, located in southern Indiana, have filed suit in the Federal Court here, naming the Indiana Industrial Board and its members as defendants, and asking that an injunction be granted restraining the board from enforcing the amended compensation act, and elimination of Section 18, which is held to be invalid and unconstitutional, in that it compels acceptance by the coal industry and exempts other industries in similarly hazardous occupations.

ILLINOIS

Chicago—The O'Gara Coal Co., which went into bankruptcy in 1912, with liabilities of almost $5,000,000, has been declared solvent by Federal Judge Carpenter. It was announced that the company would settle every claim against it except the one of Thomas J. O'Gara, former president, for $1,500,000.

Du Quoin—An organization has been perfected in this city under the name of the Du Quoin Correspondence Mining School with D. T. Fox, of Du Quoin, and John Kincannon, of St. Johns, as directors. Through this institution, miners will be given a chance to study at night and the following courses are offered: Mine manager, 1st and 2nd class; hoisting engineer, 1st and 2nd class; mine examiner; firing; instructions in electricity and other underground work.

KENTUCKY

Louisville—The directors of the Liberty Coal and Coke Co., at a meeting in this place named S. T. Ballard, president; M. S. Barker, vice-president; K. T. Cornelius, secretary-treasurer and William N. Ewald, general manager. The company operates large mines in Bell County on the Straight Creek seam.

Russell—The large number of cars passing through the yards of the Chesapeake & Ohio, at this place, is a general index to improved conditions in West Virginia and northeast Kentucky, the daily number of cars having reached an average of about 1700. Western coal from the states mentioned is weighed at Russell and much of the coal is billed from here.

The large Solvay byproduct plant in northeast Kentucky, near Huntington, under the management of A. B. Rawn, started during the week ended May 24 on a full time basis, only seven ovens having been in operation for a time.

Williamsburg—The Southern Coal and Coke Co. and its associate companies, has now reached a daily production of 10,000 tons of coal. This company has acquired and developed additional operations in the Harlan, Ky., field and new operations in the Hazard, Ky., field. Other operations of the company are in the old Jellico field near the Kentucky-Tennessee line and the Careyville field of Tennessee. All of these operations have Louisville & Nashville railroad outlets north and south, except the Hazard field, which ships only north. The Careyville operations serve only the southern trade over the Southern Railway.

ALABAMA

Birmingham—It is reported that 15 miners, employees of the Majestic Coal Mining Co., near this place, are believed to be dead as a result of the recent disaster; 14 employees have been rescued badly burned.

Montgomery—Alabama owns a large acreage of land rich in coal. The state Legislature committee on convicts and roads pronounces the system of leasing convicts to corporations intolerable. The question has come up as to whether the state shall enter the mining field as a competing corporation. The final report of this committee on the coal mining question is awaited with interest by people throughout the state. There are over 1200 convicts in Alabama capable of doing work in the mines; many are so employed now and have become expert by years of experience.

MISSOURI

St. Louis—The Western Coal and Mining Co. and the Weir Coal Co., of both of which W. P. Hawkins is president, are sinking three new mines, one north of Franklin, one near Carona, Kan., and one at Woodrow, Mo. The tracklaying and preliminary work have been completed at each of the new operations.

IOWA

Des Moines—Production statistics of Iowa for the year 1918 just compiled by the state mine inspector's office show that in spite of the agitation for increased output and the storing of coal during the summer months, there was a smaller output in 1918 than in the year preceding. The tonage of 1918 for Iowa was 8,219,138, as compared with 9,049,806 in 1917 and 7,217,979 in 1916. Lack of help, the zoning system and the refusal of the railroads to contract for coal during the spring months of the year because of a disagreement over price are said to be the principal causes for the smaller production of 1918 as compared with the previous year. The average number of employees in and around the Iowa mines was 14,563, as against 15,464 in 1917 and 15,195 in 1916. The average number of days worked in Iowa in 1918 was 207; in 1917, 240 days, and in 1916 212 days. There were 52 mining machines in operation in 1916 and 76 in 1918.

WISCONSIN

Postosi—The surface plant of the Wilson mine at this place has been destroyed by fire. The mine has not been worked for about a year and the origin of the fire is a mystery. The burned structure cost over $20,000 and was owned principally by Platteville interests.

Edwardsville—Work has been started south of this place on a large plant which is expected to begin shipping coal in the fall. The main shaft will be 12 by 16 ft. in dimension The company developing the property controls some 18,000 acres of coal and recently announced its intention to spend $500,000 in constructing a modern mine with every appliance for mining coal successfully.

OKLAHOMA

Fort Smith—Covington and Grant of this place, general counsel for the United Mine Workers of America, has notified miners on the Choctaw and Cherokee Indian coal lands in Oklahoma, to stop paying rental to the land purchasers. This action followed the withholding of confirmation of sale of such lands by the Department of the Interior. Transactions to the extent of $300,000 in Indian lands underlaid by coal are involved. Counsel for the miners interceded for the home owners in Washington, D. C.

Muskogee—President John Wilkinson, of District No. 21 of the United Mine Workers of America, states that any effort made in Oklahoma and Arkansas

to repeal the Workmen's Compensation Act will be opposed. The act as amended by the last Oklahoma legislature increased the compensation allowed coal miners, in case of disability, from 50 to 60 per cent. of the normal wages of the injured man. Coal operators and other employers are making a fight for a repeal of this provision.

MICHIGAN

St. Marys Falls Canal—During the month of April, 1919, there passed westbound through the United States Canal 415,824 net tons of bituminous coal and 142,864 net tons of anthracite. The U. S. canal opened Apr. 10, the Canadian canal opening two days later.

Foreign News

Vancouver, B. C.—The Provincial Department of Mines has voted a sum of $50,000 to aid in the development of coal, petroleum and natural gas, lying under crown lands near the Alberta boundary.

Brussels, Belgium—The International Parliamentary Commercial Conference adopted a resolution inviting the allied and associated governments to appoint an international committee. The object of this committee is to centralize information relating to the production, transportation and consumption of fuel, with the idea of bringing about thrift in its use.

Toronto, Ont.—The annual meeting of the Crows Nest Pass Coal Co. was held on May 20. The financial statement showed profits of $216,984, as compared with $57,635 for the previous year. The coal mined in 1918 amounted to 681,942 tons, and the coke produced to 183,771 tons, as against 504,768 tons of coal and 146,533 tons of coke in 1917. Dividends paid during the year amounted to $279,499, and the total credit balance was $318,497. General Manager W. R. Wilson was added to the directorate as second vice-president.

Nanaimo, B. C.—Water is being pumped from the workings of the Suquash mine of the Pacific Coast Collieries Co., which is situated some distance north of this place on the east coast of Vancouver Island. This mine was closed when the war broke out in 1914 and since then has been practically deserted. It is understood to be the company's intention to put the mine on a producing basis at the earliest possible moment.

Personals

R. W. McFadden has been appointed purchasing agent for the Buck Run Coal Co., and also the Darkwater Coal Co., with headquarters at Buck Run, Penn.

Charles A. Greene, the Chicago representative of the Borden Co., manufacturer of Beaver pipe tools, has opened a downtown office at 549 West Washington Boulevard, Chicago, Ill.

D. L. Caulten, for the past six years assistant superintendent for Berwind White Coal Mining Co., has resigned to accept a position as mine inspector for the Fleming division of the Elkhorn Coal Corporation.

A. C. Watts, the chief engineer of the Utah Fuel Co., of Salt Lake City, Utah, has also assumed the duties of geologist of this company. The office of geologist of the company, formerly occupied by C. H. Gibbs, deceased, has been consolidated with the office of chief engineer.

H. C. Hawes is the new president-manager of the Wells-Elkhorn Coal Co. in charge of the Black Diamond and Salt Lick operations of the company. He was manager of the Salt Lick Coal Co. and succeeds W. C. Hawes, formerly manager of the Black Diamond Coal Company.

Colonel G. A. Burrell, president of the Island Refining Co., 62 Cedar St., New York City, has been awarded the degree of Doctor of Science, by Wesleyan University, Middletown, Conn. Colonel Burrell had charge of gas investigations for the Bureau of Mines for a number of years and from the time this country entered the war he was connected with war work in this and allied lines.

E. C. Mahan was recently made president of the Southern Coal and Coke Co. at its annual meeting, held in Williamsburg, Ky. Mr. Mahan succeeds the late Dr. A. Gatliff, former head of the company. The general offices of this company are at Knoxville, Tenn. T. B. Mahan remains as vice president of the Southern company. N. B. Perkins, of Williamsburg, Ky., was made secretary-treasurer, and N. L. Mahan, of Knoxville, general manager.

C. D. Boyd, formerly with the Louisville & Nashville R.R., as coal traffic manager, has opened offices at 1116 Starks Building Louisville, Ky., for handling traffic matters for the Southern Appalachian Coal Operators' Association, Harlan Coal Operators' Association, and Hazard Coal Operators' Exchange. Mr. Boyd is handling general traffic matters, and has recently gotten out a 19-page bulletin to all members relative to traffic matters and movements in April.

Obituary

Thomas Monahan, manager of the Monahan Coal Co., died at his home in Butte, Mont., on May 13. He was 39 years of age.

H. L. Hubbard, superintendent of the Superior Pocahontas Coal Co., of Davy, W. Va., died on May 17. He was 38 years of age.

John P. Reese, vice-president and general manager of the Chicago & Northwestern coal properties for the past 12 years, died Tuesday, May 27, at his home, 5614 Waterman Ave., St. Louis, Mo., after an illness of several months from a complication of diseases. He is survived by his wife and two children, Ruth and Kenneth. His body was shipped to his former home at Albia, Iowa, for interment.

Industrial News

Prestonburg, Ky.—To meet the increasing demand for its coal on the Lakes, the Middle Creek Coal Co. will add new picking tables and much new loading equipment to its plant at this place.

Bluefield, W. Va.—Sales headquarters of the Pocahontas Sales Co. and of the Glen Alum Fuel Co. have been established in the Fischer Building, Chicago, Ill., with John R. Miller as office manager.

Punxsutawney, Penn.—The Pansy Coal Co., located near Valier, Penn., has completed negotiations for the leasing of about 450 acres of coal, in the vicinity of this place, from the Berwind-White company.

Charleston, W. Va.—The New River Coal Co., operating in Fayette and Raleigh counties, is understood to be having plans prepared for extensive improvements at its various plants to increase the present capacity.

Bluefield, W. Va.—A new tipple costing $15,000 has recently been completed by the Dry Fork Colliery Co. at Yukon, McDowell County, W. Va. The tipple has a capacity of 1000 tons of coal per day. The general office of this company is at Bluefield.

Wellston, Ohio—The Wellston Hill Coal Co., of this city, Homer Goddard, president, and Earl Littler, secretary, has purchased the holdings of the Coalton Fuel Co., in Washington Township, near here, and will mine the No. 2 coal on the property. The tract contains 440 acres.

Terre Haute—The Government mine rescue car which will be permanently stationed at this place was sent to Washington, D. C., for inspection by Secretary of Interior Lane and other officials interested in rescue work. The car is most complete and up-to-date.

Widen, W. Va.—Plans are in process of of formation by T. E. B. Siler, Charleston, W. Va., and associates for the development of a total of about 1136 acres of coal located in Nicholas County, W. Va. Robert L. Porter, Charleston, and Matthew Slush, Detroit, Mich., are also interested in the project.

Johnstown, Penn.—The Cambria Steel Co. is said to be considering plans for the opening of a new mine in the Rosedale district. The company recently started operations in two other mines, and within the past year a colony of approximately 500 employees has been established in the vicinity of these plants.

Birmingham, Ala.—The Macomber & Whyte Rope Co., manufacturer of wire rope and wire, at Kenosha, Wis., announces the opening of a branch office at this place under the direction of James A. Boope, southern manager, 805 American Trust Bank Building. This company's business is reported to have increased rapidly during the past few years in the South.

Charleston, W. Va.—A power house is to be added to the plant of the Kanaelk Coal Co., near Clendenin. The same company will construct more houses and will also install additional side track.

Pittsburgh, Penn.—Now that the United Coal Corporation has become the Hillman Coal and Coke Co., and the management consolidated with other Hillman companies, it is stated that the personnel of the combined management will be: William L. Affelder, general manager of the Hecla Coal and Coke Co. and the Thompson Connellsville Coke Co., general manager; Harris T. Booker, general superintendent of the United Coal Corporation, general superintendent; and J. Dickerson Martin, chief engineer of the United Coal Corporation, chief engineer.

Frankfort, Ky.—Under a decision of the Franklin Circuit Court, of this place, the Federal Coal Co., is entitled to recover $2,700 mortgage tax paid for recording a mortgage on eastern Kentucky coal property. The company purchased the tract and mortgaged it, the tax amounting to the sum sued for. Afterward the company lost its title to the land in a suit in a Federal court and a commissioner was appointed to cancel all encumbrances. The company demanded a return of the mortgage tax, contending that under the conditions the instrument filed was not a real estate mortgage.

Milwaukee, Wis.—The Nordberg Manufacturing Co. is manufacturing a new type of Uniflow poppet valve engine. It is known as the Nordberg-Todd and is built in sizes ranging from 200 to 2000 hp. for any available steam pressure, any available superheat, any available vacuum and any available back pressure. The assertion is made that under any of these conditions the engine will operate with lower steam consumption per horsepower, over wider variations of load, than any steam prime mover thus far developed. The engine can be changed from condensing to non-condensing operation, or the reverse, while running.

Huntington, W. Va.—The Main Island Creek Coal Co. will hereafter have its Western sales office at Indianapolis only instead of at Richmond, Ind., and at Chicago, Ill. The offices at both these latter points have been discontinued, according to an announcement made by D. J. Payne, of this city, general sales agent of the company. A new concern which has just entered the producing field is the Brush Creek Coal Co. Its plant has been completed and is now operating, dumping over three tipples. The company, however, proposes to use three additional tipples and has started construction work on such structures. H. C. Jones, of Logan, is president of the new company and James Gent is superintendent. The plant of the company is at Costa, on Coal River.

Du Quoin, Ill.—The Hamilton Coal & Mining Co., of Weir, Kansas, is now completing plans for the opening of a large strip mine northeast of this city, on a tract of land which was recently acquired by it. This will make the second large strip mine to be opened up in the last year within the city limits of Du Quoin. The other strip mine is owned and operated by the E. J. Scott Coal Co., a St. Louis company; at the present time this stripping has a capacity of 600 tons. The company has sufficient acreage to enable it to operate this mine for five years or more.

Stripping is fast becoming a popular method of coal mining among Southern Illinois operators. Every acre of coal land suitable for stripping is being leased and at the present time there are many tracts near Du Quoin which are under option.

Crooksville, Ohio—The Sunday Creek Coal Co. has taken over all the properties of the Sunday Creek Coal Co. of New Jersey, the Buckeye Coal and Railway Co., and the Ohio Land and Railway Co. By this transaction the Sunday Creek becomes the owner of the larger part of the holdings of the Buckeye Coal and Railway Co., of southeastern Ohio. The holdings of the Buckeye Coal Co. consist of two mines, several hundred houses, a large store, a hospital and theater at San Toy. This is one of the valuable mine properties of Ohio. New tipples, shaker screens and loading booms are being installed by the company in the Sunday Creek Valley mines, which include Corning, Hemlock, Buckingham, Congo and Shawnee. The Tropic Mining Co. has purchased the holdings of the Sunday Creek Co., at Rose Farm, the purchase including all surface, company houses and other property of the Sunday Creek Co. in that section. It is stated that the Tropic company soon will begin development work on its newly purchased territory.

MARKET DEPARTMENT

EDITED BY ALEX MOSS

Weekly Review

Soft Coal Market Generally Inactive, Although There Is Some Improvement—More Buyers Coming Into Market—Operators Not Eager to Sign Long-Time Contracts—Anthracite Industry Active, Though Not on Steam Coals

SPEAKING broadly, the soft-coal market is inactive, although there is a slight improvement evident all along the line. Coal for prompt shipment can be bought at prices lower than those quoted on contract business, making it clear that operators are taking into account the uncertainties that may surround them later on in the year. In more than one instance operators have refused to bid on contracts, preferring to take the market as they find it. Quotations for future shipments are likely to grow firmer from week to week. A few of the large consumers who had been out of the market for some time are now making purchases quietly at short intervals, but the volume of this kind of buying is small and seems to exert no strengthening effect on the prices for spot coal. In fact, prices on coal for prompt shipment have been lower the past week or two than at any other time this season.

Operators are evidently expecting labor trouble in the near future, for they are insisting on labor clauses in all contracts. Consumers have already begun to realize that it is becoming increasingly difficult to close for their future needs. Production of soft coal for the week ended May 24 totaled 8,719,000 net tons as against 11,569,000 net tons for the same period last year. Prices generally are being maintained, with indications pointing to an early advance in the better grades, such as Pocahontas and New River.

An encouraging note has been struck in the Middle West. About 75 per cent. of the steam trade in Michigan and Indiana has already been covered by contract, and if consumers in Illinois, Wisconsin and Minnesota follow suit it will enable the interior mines to work more regularly than they are now working. In the latter states probably less than 50 per cent. of the industries have contracted for their future coal supply.

There is no apparent let-up in the demand for the domestic sizes of anthracite, and retail dealers continue to be deluged with orders from consumers who are insistent upon prompt deliveries. Egg, stove and chestnut are the sizes in greatest request, while the operators and dealers find that broken and pea coal are being disposed of with difficulty. The steam sizes of anthracite, on the other hand, are somewhat draggy, and extreme cuts in price have been made on the smaller sizes, particularly rice and barley, in order to stimulate buying. On June 1 all the producing companies increased their prices on the domestic sizes of anthracite 10 cents a ton, in accordance with their circular announcement of last March, when the spring prices were established. The output of hard coal for the week ended May 24 totaled only 1,679,000 net tons, which is approximately a decrease of 65,000 net tons compared with the week preceding. During the like period in 1918 the anthracite mines produced 2,005,000 net tons.

The movement of coal to the lake docks, for transshipment to the Northwest, is moderately active. The tonnage of coal available is not sufficient to load all the carriers that offer themselves. It has not been possible to attain a loading total of 1,000,000 tons a week thus far this season.

WEEKLY COAL PRODUCTION

The improvement in production of bituminous coal which was recorded during the past few weeks continued through the week ended May 24, when the output was estimated at 8,719,000 net tons. This tonnage, while considerably in excess of the production during the week ended May 17, estimated at 8,442,000 net tons, was far below the output of the week ended May 25, 1918, estimated at 11,569,000 net tons. The daily average per working day during the week ended May 24 is placed at 1,453,000 net tons as against 1,366,000 net tons for the calendar year to date, and 1,807,000 net tons, the daily average for the same period of last year.

The production of anthracite during the week ended May 24 is estimated at 1,679,000 net tons, a decrease of approximately 65,000 net tons, or 4 per cent., compared with the week preceding. The daily average during the current week is placed at 280,000 net tons, as compared with 246,000 net tons for the calendar year to date and 334,000 net tons, the daily average for the corresponding week of 1918. For the period Jan. 1 to May 24 the production is estimated at 30,538,000 net tons, and is far below that of last year, estimated at 39,149,000 net tons.

Bituminous coal dumpings at the lower lake ports during the week ended May 17 are estimated at 911,309 net tons, and exceed the tonnage dumped during the same week of last year by approximately 115,000 net tons, or 15 per cent. For the season to date the dumpings at the lower lake ports amount to 3,132,157 net tons as against 2,843,011 net tons during the corresponding period of last year.

The demand for coal is improving, the general average of time lost on account of no market decreasing from 39.2 per cent. in the week ended May 10 to 36.4 per cent. in the week ended May 17. Excepting the Westmoreland, Fairmont, Virginia, Iowa and the fields in the western states, all districts recorded improvement in the demand for coal. In eastern Kentucky, two districts—Hazard and Harlan—report no market losses of less than one day a week and to exceed 80 per cent. operating time.

The production of beehive coke in the United States during the week ended May 24 is estimated at 249,828 net tons as against 210,657 net tons during the week preceding, and 620,090 net tons during the corresponding week of 1918. Improvement over the week preceding occurred in all the states, with Pennsylvania making the greatest gain. For the calendar year to date the production of beehive coke is placed at 8,215,277 net tons as against 11,964,490 net tons during the same period of last year.

BUSINESS OPINIONS

Marshall Field & Co.—Current wholesale distribution of dry goods is less than the extraordinary large volume of the corresponding week a year ago. More customers are in the market and all report a continuance of excellent retail business. Orders from road salesmen for both immediate and future delivery are greatly in excess of the corresponding week of 1918. Collections are excellent.

The Iron Age—Demand for steel has improved measurably and sentiment throughout the trade has turned for the better. The Railroad Administration has bought under protest the 200,000 tons of steel rails on which bids were taken May 17, paying $47 for open-hearth rails, the price named by the Bethlehem, Lackawanna, Colorado, Carnegie, Illinois and Tennessee companies. The Midvale bid was $57 for open-hearth and $55 for Bessemer rails. The Lackawanna and Bethlehem awards were 40,000 tons, while the Colorado mill received 20,000 tons and the three Steel Corporation subsidiaries 100,000 tons.

Dry Goods Economist—Highly encouraging as an index of demand for dry goods are the reports from agricultural sections, which are unanimous in pointing to continued wealth for the farmer. The labor situation in many textile centers is getting easier. The chief disturbance to production at present is the demand of silk weavers in Paterson, N. J., for shorter hours and higher wages. In one silk mill in Pennsylvania the operatives have struck with similar demands. In the strike of the operatives in New York garment factories there have been no important developments. Conferences between representatives of the union and of the manufacturers are held daily, but these have so far been without practical result.

Atlantic Seaboard

BOSTON

Widening differential between spot and contract business. Spot market reacts unfavorably under stress of present conditions. Undertone begins to change for the better. Fairmont grades still sluggish. Hampton Roads coals unchanged. Local capital shows interest in fuel oil. Anthracite demand continues.

Bituminous—The bids opened by the Navy Department on May 29 are the first

real indication of materially firmer prices on the steam grades for season delivery. It is clear that operators are now taking into account some of the uncertainties involved in contract undertakings for the next ten months, and quotations for shipments beyond the next 60 days are likely now to harden from week to week. In some instances shippers have declined to make prices for futures.

The spot market has been influenced both by the diffident buying that has prevailed from the opening of the season and by the prices at which so much locomotive fuel has been placed. The anxiety to keep mines in operation has also been a factor, but the result thus far has been without any material increase in output. So far as this territory is concerned, receipts show the same low average that has obtained since February and we have yet to see any marked increase in movement either all-rail or by water, although it is probable that the railroads from now on will make an effort to build up their reserve supplies. A few of the larger buyers who had kept aloof from the market are now making quiet purchases from month to month, or even from week to week, but the volume of coal arranged for in this way has been small rather than large and seems to have had no bracing effect on spot prices. In fact, on certain grades all-rail, spot figures have been lower the past fortnight than previously this season.

The undertone, however, is steadily changing. Some steam users have already begun to realize it is not so easy to get covered on desirable grades at the contract prices quoted 30 days ago, and while we are not yet in position to report any considerable advance in the f.o.b. mine basis, it is increasingly evident that operators are insisting upon labor clauses in all contracts.

The Fairmont district seems especially distinguished this year for low prices. The labor situation there has seemed more stable than in central Pennsylvania and there has been more effort to get spot business. At the same time this territory is always slow responding to high-volatile coals and aside from the railroads only a light tonnage has been placed. There are enough low volatiles of known quality to meet requirements thus far and it is the exception where coal of any but medium to high grade has been purchased. The through tariffs operate against coals emanating from the W. M. and the B. & O. in any case, and that is a further reason why West Virginia coals all-rail have had only a restricted market in New England.

Pocahontas and New River show no perceptible change. Prices offshore for deferred loading should soon show an upward trend, however, if the recent Navy proposals are any criterion. For the moment barge transportation is less easy to secure from the Southern ports and that, too, has caused a slight uneasiness on the part of those who continue to depend upon Hampton Roads sources. There are still selling efforts on the basis of $2.35 per net ton f.o.b. mines or $4.69 f.o.b. vessel, but apparently such offerings are more restricted than was the case a few weeks ago. Less is heard of market cargoes and on the whole there is more firmness to quotations for inland delivery. Export inquiry is being closely watched in the hope that better prospects will soon develop. At Hampton Roads the tenders to the Navy Department were in the aggregate considerably less than the requirements advertised and the trade here is interested to see what attitude the bureau officials will take.

A new development in oil is arousing some comment. The Massachusetts Gas Companies, of which the New England Fuel and Transportation Co. and the New England Coal and Coke Co. are subsidiaries, have organized an oil company to fabricate and distribute oil for fuel and other purposes.

Current quotations on bituminous at wholesale are about as follows:

	Clearfields	Cambrias and Somersets
F.o.b. mines, net tons	$2.15@2.75	$2.75@3.35
F.o.b. Philadelphia, gross tons	4.27@4.95	4.95@5.50
F.o.b. New York, gross tons	4.62@5.29	5.29@5.85
Alongside Boston (water coal), gross tons	6.10@6.85	6.90@7.35

Georges Creek is quoted at $3.20 per net ton f.o.b. mines.

Pocahontas and New River are being quoted at $4.69@5.14 per gross ton f.o.b. Norfolk and Newport News, Va. Alongside Boston the same grades are being offered at a range of from $6.89@7.24, and on cars Boston and Providence at from $7.60@7.90 per gross ton, the latter being the contract price f.o.b. cars for season delivery.

Anthracite—There is no slackening in the demand for domestic sizes. The pressure is steady both all-rail and by water to get household coal forward and the retail dealers continue to be swamped with orders from people who are insistent upon prompt deliveries. There are actual cases where small dealers have delivered during April and May a tonnage nearly 50 per cent. of what they received in the 12 months previous to Apr. 1, and instances are numerous where dealers have made deliveries of 20 to 25 per cent. of the year's business. Egg, stove and chestnut are the sizes in greatest demand, while broken and pea are little heard from. The steam sizes are draggy and radical cuts have been made in list prices, particularly on No. 3 or barley, in order to induce buying. Coastwise New England has not thus far had any greater quota than a year ago, and there is a great deal of anxiety over the outlook. If the city markets like Philadelphia and New York would ease up on their demand there would be more chance for New England. Distributors here are hoping there will be something of this kind during June.

NEW YORK

Anthracite market strong and demand steadily increasing. Production far behind and the industry faces a serious situation. Operators lack certified miners. Independent operators find good market and premiums are offered for their product. Anthracite steam sizes plentiful and prices are easy. Tidewater bituminous situation quiet. Coal moves slowly.

Anthracite—The market continues strong so far as the domestic sizes are involved, with the demand steadily increasing and dealers urging more frequent shipments. The trade is no doubt facing a severe winter, and the producers are urging early buying. Production is far behind and consumers who were slow in placing their orders are now beginning to realize that they might have to wait for their coal.

Conditions in the mining regions do not appear to be satisfactory for reducing the loss already existing in production so far this year. One reason for this, as pointed out last week, is the shortage of certified miners. This condition has existed for the past couple of years, while there is an abundance of help for the other jobs about the mines.

The mines are working steadily, but do what they will producers seem unable to catch up, even in a small way, with the heavy demand made upon them for the larger sizes of anthracite. Some operators claim to be sold ahead for several weeks for these sizes, while a few of the so-called Independent operators have let it be known that they can receive no new orders at this time.

The asking of premiums for domestic coals by some of the so-called Independent operators has been heard of, but the practice has not become general. These reports have it that as much as 30c. has been asked for some of the domestic sizes, but retail dealers so far have not been willing to pay anything above the regular company schedule, inasmuch as they have the greater part of the summer before them.

The second monthly advance of 10c. per ton for the domestic sizes, including pea coal, went into effect on June 1. It was said that some of the so-called Independent producers were adding 20c. per ton instead of 10c., while others were adding 15c. per ton.

Demand continues strong for stove, egg and chestnut in the order named. There is also a good call for pea coal.

The anthracite steam sizes are proving a burden to the trade. Factory yards along the railroads are well stocked and some of the larger producers are taking advantage of the situation to store these coals. Prices are easy, buckwheat being quoted at as low as $2.75 at the mines, rice 50c. lower and barley as low as $1.50, much depending upon the quality of the coal. Some of the cheaper grades of barley are reported as being quoted at still lower prices.

The situation regarding the small sizes is becoming serious. Dealers are refusing to make room for the surplus and most manufacturers have taken all they can handle. Then again it is possible to obtain good grades of bituminous at less than it costs to procure the better grades of buckwheat, with the result that some manufacturers are seriously thinking of using bituminous coal altogether.

Dumpings of anthracite at the railroad piers for the week ended May 30 were 4366 cars as compared with 6036 cars the week previous, a decrease of 1670 cars.

Bituminous—It has been many months since conditions in the local bituminous market have been anything like they now are. The situation is practically listless. Demand is slow and free coals are hard to move. Were it not for the quantity of coal shipped on contracts the local market would be "dead" and the piers under embargo. As it now stands, many shippers have been embargoed for a few days at a time.

Operators continue to hesitate before adding to their contract requirements. They are not willing to take on any more obligations although they would have no trouble to obtain their price. With labor as it now is, producers are not positive as to how production will be next winter. On the other hand, consumers who have held back for lower prices are now anxious to get under cover.

During the week ended May 29 the dumpings of bituminous at the various railroad docks were 5378 cars as compared with 5842 cars the week previous, a decrease of 464 cars.

Quotations on the various grades, mine price, for spot and contract delivery, range as follows:

	Spot	Contract
South Forks	$2.90@$3.25	$2.95@$3.50
Cambria County (good)	2.75@ 2.95	2.95@ 3.25
Clearfield County (good)	2.50@ 2.75	2.80@ 2.95
Reynoldsville	2.50@ 2.75	2.75@ 2.95
Quemahoning	2.65@ 2.85	2.95@ 3.10
Somerset County (best)	2.50@ 2.75	2.95@ 3.10
Somerset County (poor)	2.00@ 2.35	2.50@ 2.75
Western Maryland	2.25@ 2.50	2.50@ 2.75
Fairmont	2.00@ 2.25	2.35@ 2.50
Latrobe	2.10@ 2.25	2.25@ 2.40
Greensburg	2.25@ 2.35	2.35@ 2.60
Westmoreland ¾-in.	2.60@ 2.75	2.60@ 2.75
Westmoreland run-of-mine	2.35@ 2.60	2.35@ 2.65

There is a good demand for anthracite from Canada, the trade, according to report, being offered 50c. above current quotations for quick shipments.

Current quotations, white ash, per gross ton at the mines, f.o.b. tidewater at the lower ports, are as follows:

	Mine	F.o.b. Tidewater
Broken	$5.95	$7.80
Egg	6.05	7.90
Stove	6.30	8.15
Chestnut	6.40	8.25
Pea	5.00	6.75
Buckwheat	3.40	5.15
Rice	2.75	4.50
Barley	2.25	4.00

PHILADELPHIA

Anthracite retail orders slacken with arrival of summer weather. Dealers differ as to outlook. Operators with short production in sight expect trouble. Retailers storing pea. Egg, stove and nut continue in strong demand. Shippers loath to take new business. Pea coal sizing better lately. Steam coal unstable. June price schedule in effect. Many price rumors afloat. Bituminous dull. Rail fuel mostly covered. Better industrial buying.

Anthracite—With normal June weather prevailing there was a continuance of the slackening of interest on the part of consumers, which was quickly shown in the small number of new filling orders received by the retailers. As is usual when a sudden change in the weather affects buying, the dealers are quick to feel the change. As is often the case, also, we find they do not agree on the outlook of their business on the larger sizes of anthracite. Some argue that as there has been a very perceptible slowing up in the receipt of new business they fully expect to catch up with their deliveries by the end of June. They claim with dull business during July and August it will not be a difficult matter to stock their yards.

Those better posted dread the possibility of short supplies during the coming fall and winter. They know there is little of family sizes in storage, and that there is small possibility of the shippers filling their storage yards, because the demand is strong from all sections of the country. As a consequence there is small chance of there being a surplus.

It is just this condition which has strengthened the pea coal market. A number of the larger and also wiser buyers are slowly accumulating comfortable stocks of this size. Most dealers report their sales small, but many of them have ceased to wait for bargains and are buying slowly but regularly. The winter of 1916-17 convinced them the public will not do without fuel because they cannot obtain their favorite size, but will buy anything rather than do without.

The demand now for egg, stove and chestnut continues unabated, and today there is small tonnage in the yards, and it is nothing at all unusual to find yards without either stove or nut for short intervals.

No house is soliciting business on the family sizes, with the possible exception of pea. As noted above, this latter size has greatly strengthened and whereas some of the larger shippers a few weeks ago were running some of this coal into storage, the entire production is now being absorbed. The big companies are especially careful not to commit themselves to furnish coal to any dealers heretofore known as customers of the smaller operators, or to promise any more coal than furnished in other years. The fear of paying substantial premiums next winter is spreading and no doubt influences many in their efforts to make company connections. The representatives of the latter are very frank in explaining their prospective production does not warrant assuming new obligations.

As for the past six weeks, stove coal is by all odds in the strongest demand and in shortest supply here. Chestnut too is most active and many former buyers of pea coal have turned to it. The dealers account for this by the reason that when the price of pea was increased the size was reduced. Undoubtedly much coal came to market during the past two winters billed as pea coal that in reality was a small amount of pea mixed with large buckwheat.

Most operators have resumed their old standard of sizing and are now shipping a high class pea coal, which if continued will go far toward regaining the lost business. We have found some dealers willing to risk the guess that as the demand increases the size will again be reduced. Their judgment is based on their knowledge of the market being long on buckwheat. The call for egg remains unusual, and if this market has fallen off in its demand for pea it surely has increased on egg.

The steam coal market is quite unstable. The production of buckwheat is beyond the demand of the trade and quite a little tonnage is going into the storage yards. Rice and barley are particularly burdensome to the operators, and the storage yards are almost glutted with these sizes.

With the first of the month all of the companies increased their prices 10c. per ton on the family sizes in accordance with their circular announcement of last March, when the spring prices were established. Some of the smaller houses, following the plan adopted by them last month increased 15c. a ton, making them now 10c. higher than the company figures, and there are rumors of even greater increases.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$5.95	$7.80	Buckwheat	$3.40	$4.45
Egg	6.05	7.90	Rice	2.75	3.65
Stove	6.30	8.15	Boiler	2.50	3.50
Nut	6.40	8.25	Barley	2.25	3.15
Pea	5.00	6.60			

Bituminous—While some interests profess to see signs of improvement, others are extremely doubtful that any particular change for the better is in sight. It may be that the settlement of the railroad fuel problem has helped the general situation, but certainly the prices received for this coal are far from satisfactory and a good deal of the tonnage has been taken by concerns who have not heretofore participated in this business. The latest company to close was the Philadelphia & Reading, although prices have not yet been published on this business.

There is little spot trade; but some of the industrial plants are increasing their orders and it is just possible that business may pick up slowly during the summer. As a matter of fact many shippers feel that after the peace treaty is finally negotiated there will be something of a general resumption in trade.

There is little fluctuation in prices and they rule about as follows:

Georges Creek Big Vein	$2.90 @ $3.00
South Fork Miller Vein	2.90 @ 3.00
Clearfield (ordinary)	2.75 @ 3.90
Somerset (ordinary)	2.55 @ 2.70
Fairmont lump (ordinary)	2.40 @ 2.50
Fairmont mine-run	2.15 @ 2.25
Fairmont slack	1.90 @ 2.00

BALTIMORE

Improvement expected in soft coal market in near future. Anthracite demand keen with little coal arriving. Export shipments show increase.

With prices holding firm the bituminous market bids fair to show some improvement in the near future. It is the view of the trade that while dealings continue to be confined practically to the spot market, the continued inquiry would make it appear that in the near future many consumers are going to get under cover. The warning that production is not going to be able to meet the demand of the future unless mines are kept working is being heeded by many, and this will doubtless help stabilize market conditions soon.

For the best grade of coals $2.75 at tide was the high mark. This went as low as $2.50, while for the medium grade fuels $2.30 to $2.40 were the best prices. The cheap grade of fuels was offered at as low as $1.90@2, but the buyers here decline to stock any fuel of the inferior grades. The market here is strong for the best grades.

The trade is somewhat agitated over reports sent out from Washington, which set forth that President Wilson favors Government control of coal, oil and gas. Leaders of the industry point out that any further Federal control of coal would sound the death knell of the industry, but there is a sort of feeling of relief in the fact that a Republican Congress holds the whip hand and will not permit any return to conditions of a war nature.

Exports during the week picked up somewhat, and 28,963 tons of cargo and 3700 tons of bunker coal left this port for other shores. Complaint is being made of the red tape surrounding the obtaining of a charter for bottoms for foreign use. As bottoms become more and more available it is expected to provide for the rapidly increasing foreign business here. Brazil, Argentina, Costa Rica, Italy and Sweden are some of the ports of destination of the vessels leaving this port. Foreign buyers had many feelers out, but no business was closed and the cargoes leaving port were taken from the spot market.

In the anthracite market there is little change. Receipts continue to be insufficient and there is no improvement in sight. Dealers continue to urge householders to place their orders for delivery despite the fact that the April business in some instances is not yet out of the way. There is being conducted an advertising campaign by some of the dealers to stimulate buying, even with the shortage.

Lake Markets

PITTSBURGH

Demand slightly improved. Consumers conserving remaining stocks. Steel mill consumption more promising. Slack easier.

There has been a slight improvement in the line demand for coal, and with a further increase in lake shipments production in the Pittsburgh district is somewhat heavier, being estimated at well above 50 per cent. of capacity.

The steel industry has not decreased its coal consumption any farther, as with larger bookings of steel orders in the past two or three weeks than for a long time it is tending to increase its mill operations, whereas since early in the year the trend of mill operation has been constantly downward.

There is no longer much drawing upon stocks for consumption, the disposition being to hold such stocks as remain. Consumers observe that they can buy coal for prompt shipment at lower prices than they can buy for deliveries through the winter. They have to choose between believing that the coal operators are altogether wrong in their price views, or using purchased coal now at the special prices and saving their stocks for later consumption.

Slack continues to grow easier, on account of heavy production due to the movement of ¾-in. in the lake trade, and on steam slack the market is about 10c. easier on both steam and gas slack, while mine-run is unchanged. We quote: Best grades gas coal—Slack, $1.70@2; mine-run, $2.35; ¾-in., $2.50@2.60; 1¼-in., $2.60@2.70. Steam—Slack, $1.60@1.80; mine-run, $1.90@2.35, all per net ton at mine, Pittsburgh district.

BUFFALO

Slight improvement in bituminous. Not much prospect of a stir yet. Shippers confident. Industries moving slowly. Rush for anthracite. Lake shipments light.

Bituminous—The demand picks up a little here and there, but it is remarked by a leading jobber that nobody can sell coal from the office and it takes a good salesman to do much business on the road. Still there are those who do make fair sales and they are kept moving. Canada is buying a little more freely, but it all shows little more as yet than a running out of stock.

The movement of bituminous is about as formerly. Spotty conditions in the trade are reported by many jobbers. This usually precedes an increase of activity, but it may not happen right away. Still the general belief is that it will come before fall. Prices have sagged a little, but only slack shows any marked decline. Quotations: $4.55 for thin-vein Allegheny Valley, all sizes; $4.45 for ¾ Pittsburgh and No. 8 lump; $4.30 for same, ¾ lump; $4.05 for same, mine run, and $3.65 for all slack, per net ton, f.o.b. Buffalo.

Anthracite—The trade is hampered by the continued light mining. Somehow the operators are unable to keep up with the demand. Either the lake or the all-rail trade would take most of what comes this way, and the local trade is also still large. Consumers hear that a winter shortage is likely and they are eager to buy. The advancing price is also a spur, but the distributors are not able to meet it. Probably this state of things will last nearly all summer, but if so the consumers will be much better supplied than they ever have been at the outset of cold weather and ought to be able to get along so much better.

The lake trade is showing the decline of mining more than even the failure to meet the local demand. City distributors now say, though, that they are able to fill all orders and do not believe they will increase again right away, unless some new scare is sprung on the public. The lake shipments declined to 48,225 net tons, of which 13,800 tons cleared for Chicago, 8300 tons for Fort William, 7800 tons for Duluth and Superior, 7300 tons for Sheboygan, 3425 tons for the Canadian Sault, 3400 tons for Milwaukee, 900 tons for the American Sault, 3300 tons for Manitowoc.

Freight rates remain at 52½c. to Chicago, 47½c. to Milwaukee, Manitowoc and Sheboygan, 42½c. to Duluth and Fort William, $1 to the Sault.

CLEVELAND

The coal trade is reflecting the general improvement in business, and steam-coal users who for some months now have been indifferent are displaying interest. Slack is going more readily, while the lake trade is absorbing every ton arriving at Lake Erie docks. Prices, especially of domestic grades, are stiffening.

Bituminous—The operator without contracts today considers himself fortunate. In every quarter sentiment is the same—prices are going to advance steadily and a real shortage of coal threatens. Every day seems to bring forth new and larger inquiries, and the operator who has tied up a large part of his production in railroad fuel at $2 to $2.10 and lake coal at around $2.35 and $2.40 is wondering where he is going to get off. Surplus piles of slack will melt away much quicker than anticipated, and even in the face of the huge stocks at the mines some operators are figuring on putting in additional crushing equipment. The prediction is made that Dec. 1 will see slack quite short. As $1.40 slack contracts are ending they are being replaced by $1.50 and $1.60 slack. Mine-run and prepared sizes also have become much firmer, and it is doubtful if much of either grade can be touched for less than 10 to 20c. higher than was asked a month ago. Almost frantic efforts have been made lately by some of the railroads to place $2 coal, but their efforts have been fruitless. Increasing operations in the iron and steel and the rubber industries of northern Ohio insure a steadily advancing demand for coal.

The more domestic bituminous and Pocahontas is advanced the greater the demand that comes out. Forked Pocahontas now is quoted at $9, net ton delivered, by the larger retailers and this figure represents a 75c. advance in six weeks. West Virginia splint also has been marked up, and now is quoted at $7.75 to $8. Dealers continue to do a winter business.

Lake Trade—Lake Erie car dumpers continue handling about 750,000 tons of bituminous, including vessel fuel, a week, which is a slight increase over the rate at this time last year. Coal is so much in demand in the Northwest that some of the large freighters are coming down light for coal, thus reversing the usual order. A large part of the coal that is going up the lakes has not yet been priced.

DETROIT

Demand for bituminous is light in both the steam and domestic branches of the trade, despite price concessions.

Bituminous—Unsatisfactory conditions are still reported in the bituminous coal trade in Detroit. Jobbers and wholesalers

say buyers are not showing the active interest in the market that should be developing to assure an adequate and equitable distribution of coal before winter. In their opinion affairs are shaping themselves toward a situation in the fall that will draw all the buyers into the market, bidding against each other for coal that the mines perhaps may be unable to supply, even at higher prices.

Users of steam coal, with a few exceptions, are holding back. The impression prevails among some of the jobbers that they are waiting in the expectation prices will be lowered as the summer advances. Such an expectation, the jobbers say, is certain to meet with disappointment. They look for an advance as a more probable development of the later season trade.

Though smokeless coal was one of the most popular forms of fuel in many Detroit establishments before the war, little of it is now obtainable. Lump and egg are said to be so rare in the local market that quotations of $3.50@4 a net ton at the mines are conceded to be undependable. Small lots of mine-run are reported to bring $2.75.

West Virginia gas and splint lump are quoted at $2.75, mines; 3-in. lump at about $2.50; mine-run at $2.10@2.25, and slack at about $1.85. For Hocking domestic lump the mine price is given as $2.50; mine-run $2, and slack $1.50, while other coal from Ohio is said to be offered at about the same prices.

Anthracite—Household consumers seem to have forgotten their disappointments and trying experiences of the last two years in trying to get anthracite. The number of buyers stocking up for winter is not so large as dealers would desire. The supply of prepared sizes seems to be large enough to fill a greater number of orders than are being received.

Lake Trade—There is a moderately active movement of coal from mines to docks for lake shipment, but the supply is not sufficient to load all the carriers available and a loading total of 1,000,000 tons a week has not been attained this season. Inability to get downbound cargoes is causing some vessels to come down light for coal.

COLUMBUS

There is a good demand for smokeless and the better grades of domestic coal in central Ohio territory. Contracting for steam tonnage is still slow, owing to uncertainty in price. Lake shipments are becoming heavier as the season advances. A marked improvement is looked for in the near future.

Domestic users are heeding warnings that coal will likely be scarce next fall and are buying more liberally than formerly. This fact is stimulating the domestic trade, more especially in Pocahontas and West Virginia splints. Hocking and Pomeroy coal are also being bought more actively by dealers. Retail stocks are somewhat low for the time of the year, and dealers are inclined to stock up to a certain extent. Retail prices are still fairly well maintained, although some low quotations are being made. On the whole the domestic trade is becoming better and an improved tone to the trade is noted.

Steam business is still slow because of uncertainty as to the future. Reserve stocks are still being used and thus contracting is now active. Large users are able to buy coal in the open market in case they have no reserves. There is an oversupply of the small sizes, and that is the worst feature in the trade. The production of lump is restricted by the inability to dispose of screenings. Rubber plants are still pretty well supplied with fuel, and iron and steel plants are not disposed to contract.

The lake trade is becoming more active as the season progresses. Shipments at the lower lake ports are increasing from week to week. A large part of the shipments are made by concerns having their dock connections in the Northwest and the question of price does not enter into the transaction. Some agreements to move lake tonnage on a tentative contract have been made and a fair tonnage is going forward. The question of lake price is still unsettled although prices seem to be settling around $2.35 for eastern Ohio 3-in. and about the same for Hocking and Pomeroy grades.

The output is fairly good in all of the producing fields of the state. This is especially true where lake tonnage is being mined. In the eastern Ohio field production is about 60 per cent. of normal. In the Hocking Valley and Pomeroy Bend fields it is about 60 to 65 per cent. Other fields are not showing up quite so well as far as production is concerned.

Prices per ton delivered in Columbus are:

Hocking lump	$5.50@$5.75
Pomeroy	5.95
Pocahontas	7.00
Splints	6.00@ 6.25
White ash	6.25
Island Creek	6.25
Semi-smokeless	6.75
Wheeling Creek, Kentucky	6.75

CINCINNATI

Outlook is brighter. No contract business being sought as conditions in the future are being discounted now.

The outlook for the coal trade is brightening up somewhat. The uncertain business of the past few weeks is being replaced by trade of the firmer kind. There has been no exceptional demand for any grade in particular, however, all kinds moving in a satisfactory manner. Domestic grades have shown a decided improvement, and the Queen City coal men consider that this augurs well for the coal business.

The contract business has shown practically no activity, as has been the case in the past month or so. The coal men are not worrying about this, some of them, in fact, are not looking for this business at all. They claim that the state of the coal industry in the fall and winter of this year is quite uncertain, and they are anticipating some little trouble in the matter of transportation. They also claim that the labor conditions at the mine will be a little unsettled this fall, and taking these two items into consideration they are not really anxious for the contract business on a large scale.

The prices of lump coal at the mines are firmer. The movement of coal to the lakes and the northwest is reported as being comparatively light, but the belief is expressed that this trade will begin to pick up in the near future. The receipts from the mines during the past week have fallen off somewhat, but the local coal men say that they are in a position to take care of orders in a satisfactory manner, and no particular anxiety is being felt in regard to this item.

The Hamilton County Commissioners have awarded the contract for coal for the different county institutions to the James P. Bolger Coal Co. The Bolger Company's bid was $5.25 a ton for smokeless run-of-mine, $4.90 for smokeless nut and slack, and $4.49 for bituminous nut and slack.

LOUISVILLE

General movement from Kentucky mines improving, with domestic in excellent demand. Production showing steady increase, but reported to be held back slightly on account of labor shortage in eastern Kentucky field.

The demand for good block coal is better and is increasing somewhat, owing to a greater percentage of summer stocking orders from domestic consumers. Steam coals of all grades are draggy, spot coal being sold at low prices approximately, but contract coal is holding nicely. Low-grade coals are in poor demand in practically all sizes. The greater proportion of the stocking now being done is on high-grade block, as consumers are anxious to lay in sufficient stocks of good coal while it can be had.

It is claimed that with the improvement in demand the eastern Kentucky field is again feeling the effects of a short labor supply. It is held that until European labor is again imported there is not much prospect for any material improvement in the labor supply as a whole. Car supply is adequate, with all mines reporting full deliveries. Mines for the most part are working full time, but are not making full shipments. There is now a good movement to the Lake district, composed mostly of 2-in. and up block, which is increasing the difficulty in disposing of nut and slack. Railroad contracts have taken up a considerable volume of annual production, guaranteeing a fair tonnage and making for a higher and stronger market on contract coal.

A prominent producer and jobber of Louisville, in commenting on the general situation, in part said: "The United States will be in the grip of a coal famine within 90 days if coal production does not increase. Production is far below that of the war period, owing to several factors, chief of which is that the consumer is not buying coal. In eastern Kentucky many mines are short of labor, and western Kentucky mines are idle because of lack of business. Many miners in eastern Kentucky who could work full time are loafing on the job and only putting in part time. Coal companies in the city are afraid to buy heavily because consumers are not stocking and are not taking the customary quantity of coal from the agents' hands."

Prices as a whole are fairly firm and slightly stronger, with average good eastern Kentucky grades quoted at $3@3.25 per ton for block and $2.25@2.40 for mine run. Nut and slack is selling on spot at $1.50@2, with contract nut and slack quoted at $1.85@2. Jellico block is quoted at $3.35@3.50 and some good Blue Gem at $3.75, Straight Creek being offered at around $3.25. Western Kentucky is quoting block at $2.25@2.55, and mine run at $1.90@2.10, with nut and slack at $1.50@1.85 and thin screenings at $1.40 and up.

BIRMINGHAM

Shortage in domestic coal strengthens the market sharply, and when obtainable brings premium prices. Little or no change in actual sales of steam coal, though inquiries are more frequent and encouraging.

The fact that domestic grades of fuel are now so hard to obtain has resulted in the sales of such fuel being made at from 25 to 75c. per ton for the small tonnage available to the trade at this time. Most all of the domestic producers have sold up anticipated output through the year and dealers are now finding it next to impossible to place orders with brokers or at the mines. This scarcity applies to not only the best grades of domestic coal, but in a large measure to the medium and lower grades as well. Quotations effective June 1, based on the schedules arranged Apr. 1, providing for an advance of 10c. per ton each month through September, are as follows per net ton mines:

	Lump and Nut
Black Creek and Cahaba	$3.95@4.60
Carbon Hill	3.25
Corona	3.50
Montevallo	5.00
Big Seam	3.00

There has been no change in the steam situation as regards business actually booked, but indications point to an improvement in the market at an early date. Inquiries are better and of a more encouraging tone and coal men anticipate a material betterment is near at hand.

Coke

CONNELLSVILLE

Second half furnace coke contract negotiations delayed by stiffer price views of operators. Production shows slight recovery.

Connellsville coke operators have become very stiff in their views as to prices of coke, particularly for the second half of the year. Unless the blast furnaces are willing to pay considerably higher prices for second half than they were expecting only very recently to pay, contract negotiations are likely to be blocked. Compromises might be effected by making contracts on a sliding-scale basis, pricing coke from month to month relative to the prevailing market price of pig iron, otherwise coke is likely to be bought and sold from month to month at such prices as have to be agreed upon.

As last week, the usual quotation on spot or prompt furnace coke is $4, but there is less chance than formerly of shading this figure, and the lowest priced sale reported in the past week was $3.85. Off grades might go for less, but there is little production of off grades. The plants regularly making lower grades are closed and those operating are careful to make the best coke possible. Spot foundry coke remains at $4.50 for very ordinary brands, good brands readily commanding $4.75 or $5 as they have done right along.

Three weeks ago there seemed to be a prospect that many operators would offer second half furnace coke at $4, a few, making the best brands, asking $4.25, while furnaces seemed to expect to buy at about $3.50. While they had been paying about $4 for May deliveries against monthly adjustment contracts, and would probably have to pay the same for June, they expected the new half year to present different conditions. Operators, however, failed to name the expected quotations, and have

been indisposed to make any quotations, soliciting bids, while the furnaces do not care to make bids. In the past few days some operators have intimated they would consider a price in the neighborhood of $5, and as that is out of the question from the furnacemen's viewpoint the contract situation will have to await further developments. It is a small matter, however, since between two-thirds and three-fourths of the region is closed anyhow. Many furnaces are out of blast and many of those running are using byproduct coke. No contract market is quotable, and the spot market is quotable at $3.85@4 for furnace and $4.50@5 for foundry, per net ton at ovens.

The "Courier" reports coke production in the Connellsville and Lower Connellsville region in the week ended May 24 at 108,073 tons, an increase of 24,789 tons over the preceding week, but a smaller tonnage than in any week prior to that ended May 10.

Buffalo—The trade is not improving. Local furnaces are all terribly slack, some of them practically shut down on account of the failure of iron to sell. At the same time it is noticed that the stock market shows a decided advance in the quotations of some of the securities. Ore is not moving any faster than formerly, so that much of the lake fleet will be idle soon unless an improvement sets in. Quotations remain weak at $7.25 to $7.60 for 72-hour Connellsville foundry, $6.60 for 48-hour furnace, and $6.10 for off grades.

Middle Western

GENERAL REVIEW

Business is picking up all along the line. The latest reports from our mid-western coal fields are all encouraging, so far as sales are concerned. The current demand for coal is good, as is the number of contracts reported closed.

As was expected, as soon as the big buyers of coal learned that the railroads were purchasing heavily, they came into the market and also showed a desire to cover their requirements with contracts. The result has been that an encouraging number of large tonnages have been sold, but it is rumored at figures more advantageous to the operators than the coal sold to the railroads.

In Michigan and perhaps Indiana, the majority of big steam plants have covered their coal requirements by contracts, which have been closed in the last few weeks. In one Michigan manufacturing center a careful investigation showed that practically all of the big steam users now get their coal on contract. It is probably a fact that at least 75 per cent. of the steam trade in Michigan and Indiana is covered by contracts. This situation is not true of Illinois, Iowa, Wisconsin and Minnesota, as probably less than 50 per cent. of the industries are covered. It is pretty generally thought that the states just mentioned will follow in the footsteps of Michigan and Indiana, as the general public is becoming more acquainted with the seriousness of the situation, and realizes that if it does not get its requirements covered soon it will undoubtedly have serious troubles over obtaining an adequate supply a little later.

It is now pretty widely known that the railroads have succeeded in purchasing their coal considerably below the figures set forth by the Fuel Administration. It is also well known that the railroads were unable to get any concessions from the steel manufacturers, and as a result have had to pay the price on whatever purchases were made. This situation has taught rather a bitter lesson to local operators, and has shown them the advantages of a strong association. It is fairly well known that the railroads' tactics in purchasing Indiana coal have given a big setback to several operators' associations in the Indiana coal-producing districts. Already a number of operators who made special low prices to the railroads are regretting their action, and it is thought that these operators will continue regretting it as the season advances.

The proposed increase in freight rates on practically all coal used in this territory has raised a protest from the coal-consuming public. In fact, it has added some to the present unpopularity of the idea of government ownership for the railroads. The proposed increase, however, has had one beneficial result, in that it has stimulated buying, both by steam users and domestic trade. When the advances are in effect, the demand for coal will probably be so strong that the increase will have but little effect on the current market. The coal trade is now confidently looking for better business and indications are that the trade will not be disappointed.

CHICAGO

Price cutting on low-grade coals, but good grades bring maximum. Prepared sizes of Pocahontas hard to obtain.

Until a day or so ago, Chicago was having a very backward spring, with cold raw weather and plenty of rain. This stimulated both the domestic and steam situations and has forced considerable buying.

The Franklin County operators report much better business in Chicago and suburbs, and this is also true of the Indiana Fourth Vein operators. The coal from less favored districts continues to be a drag on the market, and some price cutting is reported. The high-grade coal prices remain firm, with no sign of weakening; in fact, on the contrary prices in some cases advance ten cents per ton on domestic sizes, effective June 1.

The Pocahontas situation is getting stronger every day, with many dealers offering to place orders for mine-run at $3 mines, with few takers. Prepared sizes of either Pocahontas or New River are almost impossible to obtain, with prices firm at $4.25 to $4.50 f.o.b. mines.

The demand for southeastern Kentucky coals, especially from the Hazard district, continues strong, and prepared coal from that field is moving at from $3.25 to $3.50.

ST. LOUIS

Market is quiet on all sizes of steam and domestic. A little country business in evidence on threshing coal, but otherwise market is inactive.

June comes in under favorable auspices. The buyers seem to be awakening in a general way to the fact that coal is not going to be plentiful and easy to get from now on, and there is an inclination on the part of some few to get in under contracts. The largest piece of contract business reported the past week was that of the Light and Development Co., which went to the Big Muddy Coal and Iron Co. for approximately 105,000 to 110,000 tons of steam coal for its plants in St. Louis and southeast Missouri. The contract covers a period of one year. The prices were not made public.

Locally, the situation is bad. Little domestic coal has been ordered for storage so far, but indications point to June as a good storage month with the climax perhaps in July. There is a shortage of anthracite in the St. Louis market, owing to the sudden demand for anthracite storage coal. The scarcity is principally noticeable in the egg size, and there is little hope held out for any great tonnage of this coal moving in for some time to come. A little Carterville is being put away, but the business has not started as yet.

In the Standard field the mines continue to work one and two days a week and coal is selling below cost. Screenings have stiffened up a little, but not enough to justify any material advance in price. Many mines are loaded up with lump that has been on track for upward of two weeks. In the Mt. Olive field conditions are somewhat improved, but are not anywhere near being satisfactory.

A little railroad coal is moving out of both the Standard and Mt. Olive fields, but not in the volume that it should in view of what the condition is likely to be in the future.

In the Carterville field of Williamson and Franklin Counties, as well as in Perry County, screenings are long. Many mines are unable to move their screenings, while domestic sizes, as well as the smaller sizes of nut, are in good demand. Working time is exceptionally good in these fields, everything considered. Cars are plentiful and service shows a little improvement.

The country demand for Illinois coal is better, especially from threshing section, and this is likely to continue for the next few weeks.

MILWAUKEE

Coal market enters upon summer stage of quiet. Deliveries increasing. Receipts of anthracite at a pause.

The coal market at Milwaukee has reached the summer stage of quiet, but deliveries are increasing, now that consumers are seemingly convinced that fuel prices will advance rather than decline as the season advances No additional consignments of anthracite have reached port since last week's report, but soft coal stocks at the various yards have been increased by 111,340 tons. The total receipts of coal thus far since the opening of navigation foot up 158,539 tons of anthracite and 578,051 tons of bituminous. Last year the receipts up to June 1 represented 93,564 tons of anthracite and 389,547 tons of soft coal.

The City of Milwaukee will advertise for bids on the coal supply for various public institutions, between June 10 and 15. Last year the fuel for such use cost the city $390,847.

General Statistics

NORFOLK & WESTERN TONNAGE

Below is a statement of the coal tonnage from mines on the Norfolk & Western R.R. and from other railroads, for the month of March, 1919:

From	Net Tons
Pocahontas Field	1,244,660
Tug River Field	255,581
Thacker Field	171,921
Kenova Field	68,089
Clinch Valley Field	81,838
Other Norfolk & Western Fields	4,212
Total Norfolk & Western Fields	1,826,301
Williamson & Pond Creek R.R.	102,978
Tug River & Kentucky R.R.	51,544
All other railroads	91,217
Grand total	2,072,040

COAL AGE

Volume 15 New York, June 12, 1919 *Number* 24

Every Period Has Its Own Ambitions

By R. Dawson Hall

EVERY active man has his ideals and purposes, and it is only in their accomplishment that he finds any pleasure. In every period of the world's history there has been a certain definite trend toward an ideal. If that ideal was one that was good for the world at large, then the results were good. But on the whole, much the same effort and much the same idealism always stirred active men regardless of the way in which they wended.

There has been a period when, as we put it, men strove solely for money. It would be better to say they sought for industrial power as measured pecuniarily, for nearly all the profit made they put back into industry. It was a period of real frugality. Few industrial leaders spent much money on their own comforts and pleasures. The captains of industry were master cogs in the industrial machine, who, while they helped to drive it with much noise and heat, were also driven by it. Their ideal was large industrial accomplishment. It was no mean ideal after all. It was often attacked by those whose ends were solely to acquire money and the comforts that went with it, and who wanted no part in the industrial machine, either as master cogs or as specks of sand on the brake wheel.

But there have been times when money figured but little, directly or indirectly. Many have represented them as better than the times of what they please to call "money-lust," but most of us know they were not. Thus it was in the days of the Crusades, when the desire of every active man was to spend himself in the wars, when the rich man was regarded with little but contempt. At other times the call that sounded largest to the world's leaders was to build spacious cathedrals, miles of cloisters and acres of nunneries. In others, as in England before the war, the aim of the idealist lay in public life and rarely, if at all, in making money. General approbation, whether in public or in private, whether expressed volubly at the hustings or quietly by the fireside, was all that the Englishman of family believed was really worth the while.

They come and go these moods of men. Active men are always active in seeking such ends as present themselves as being worthy. Today it seems as if a new period approached when the leaders of men would aspire, not merely to control the finances of industry, but to be acclaimed leaders of the rank and file employed at their plants. They will care less about the dividends of their factories and, therefore, about the extension of them, than upon the reaction of their operations upon the lives and hearts of their employees and their families.

Ambition they will still have. They will still scurry along the road as before, but it will be a different road. A new goal as compelling and as pleasing as the one they will have deserted will lead them on.

Where before they looked at success of the industry, now they will look at turnover, not indeed as an uneconomical and inefficient leak in industry, but rather as being an evidence of their unfortunate unpopularity as industrial leaders. Where before they sought to lay off every unnecessary man, now they will try and keep all their employees working steadily, even at some loss, because the happiness of their men will be their aim rather than such success as will place them in control of larger industrial forces.

The change may come slowly, but it seems to be on its way. It will not be without its drawbacks to the Nation as a whole, and it will not be without its advantages. A sheltered workman is sometimes a contented man and produces a large product. Again, he is sometimes an inefficient man, seeing that efficiency is no longer a *sine qua non* for employment. In a nation when men are inefficient, wages must be low and living conditions hard. So the desire for the approval of the workingman may work to the detriment of that sheltered employee. The rough-and-tumble ideals of the passing day may after all—who knows?—be more kindly than the industrial-leadership ideal that seems to be likely to dominate tomorrow.

Vesta Coal Co.'s Modern System of Mine Haulage

By Ralph W. Mayer
California, Pennsylvania

WESTERN Pennsylvania coal mines have some of the most extensive wire-rope haulage systems in the country. In some of the modern mines of this section underground and surface transportation of coal is effected by a combination of rope and electric haulage. The lowest coal haulage cost in the world, per ton-mile, from the working face in the mine to the point of consumption is probably that of the Vesta Coal Co., at California, Penn., a subsidiary of the Jones & Laughlin, Ltd., of Pittsburgh, Penn. The mines of this company possess a number of natural advantages all of which are fully utilized. The Jones & Laughlin company consumes the entire output of the Vesta mines, which in 1916 amounted to 3,000,000 tons; since that time this tonnage has been increased. These mines work steadier than operations which sell their coal in the open market, and thus the Vesta company is enabled to reduce overhead expenses.

The Vesta coal-haulage system includes electric motor transportation from the coal face to a central underground station where the motors leave their loads; a tailrope haulage system handles the cars from this point to the tipple. The haul from the tipple to the point of consumption is by water, the cheapest transportation known. The main electric haulage roads leading to the central gathering station vary, being from 2 to 5 miles in length; the central station is about 4½ miles from the tipple, which is on the Monongahela River. Thus the distance from the tipple to the innermost workings is something like 10 miles. The coal seam outcrops about 40 ft. vertically above the river and a steel trestle a half mile long connects the mine opening with the tipple (Fig. 1). The trestle and haulage road with the unique overhead arrangement for carrying the electric power cables is shown in Fig. 2. The coal runs by gravity from the tipple into barges on the river and is unloaded again at its destination by huge power shovels. A conveyor line for loading coal into railroad cars near the tipple is shown in the background of Fig. 1, in the illustration to the left.

The coal seam is practically level in the Vesta mines, but in case of variation from this rule the dip is toward the river and in favor of the loads. The method of mining here includes main haulage roads driven on the butts of the coal; face entries are driven from the main roads, and butt entries, in turn, are driven from these face entries and practically parallel to the main haulage roads. Thus nearly all the rooms turned off the butt entries are driven on the face of the coal and mining is facilitated thereby. Throughout the mine the tracks are run right up to the face, no coal being shoveled twice; it is shoveled direct from the bottom at the face in both rooms and entries.

Mechanical haulage is used exclusively at the Vesta mines, no animal transportation of coal being employed at all at this plant. There are 44 electric haulage locomotives used underground here, a 30-ton six-wheel motor being the largest size in service at these mines. Thirteen-ton motors are used generally on main haulage roads. The gathering motors are 4-, 6-, 8- and 10-ton machines equipped with cable and reel to enable the motors to run into rooms. The gathering motors handle the cars from the partings on the main haulage roads to the rooms.

All main haulage roads meet at a central station where

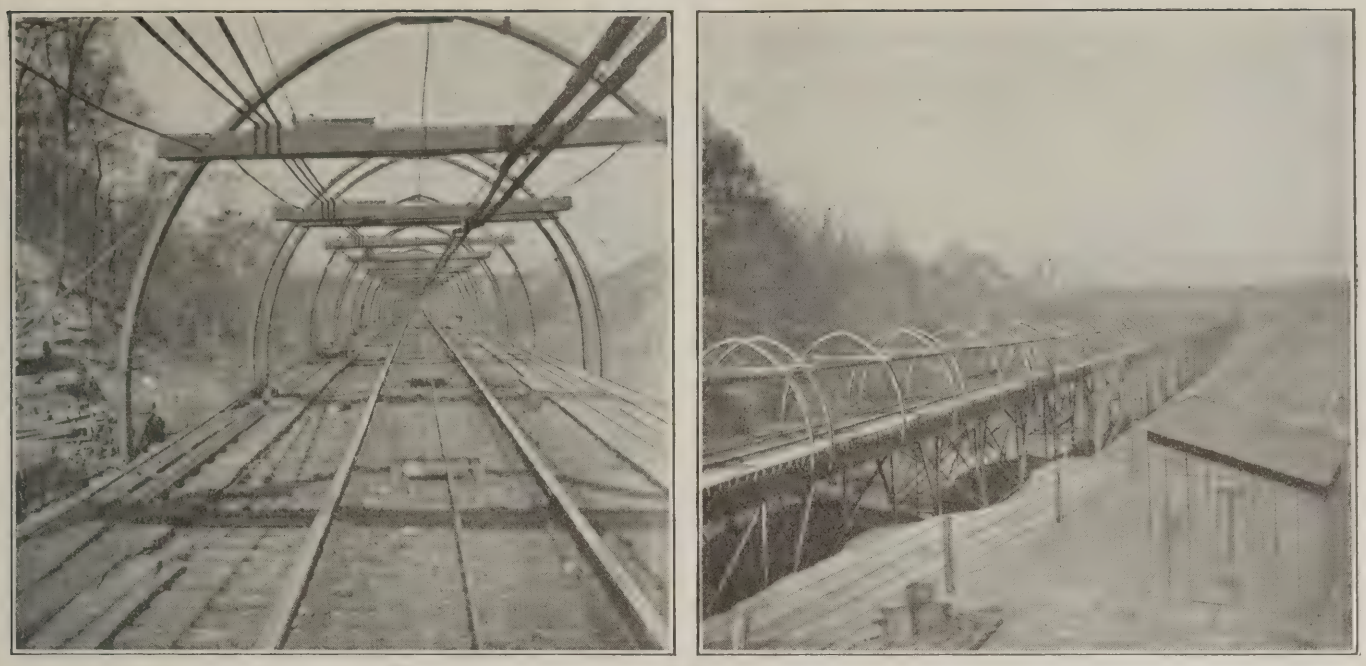

FIG. 2. VIEWS OF STEEL TRESTLE CONNECTING VESTA NO. 4 TIPPLE WITH THE MINE

the motors leave their trips of loaded cars. This station has both an empty and loaded track, each being about 2400 ft. long and holding some 240 cars. The length of the main haulage roads feeding this central station varies from 2 to 5 miles. The longest of these haulage roads has three partings and haulage sections on it, to which the gathering motors pull coal. The coal left by the gathering motors at the partings on this road is hauled by a 30-ton motor to the central gathering station. This giant motor is easily capable of handling 400 tons of coal on one trip; its usual load is about 100 cars. There are six main haulage roads; the five not covered by the 30-ton motor are served by 13-ton motors.

The section gathering stations on the main haulage roads are made by driving an entry through the solid coal. A pillar, locally called a rib, is left between it and the main haulage track. This entry is driven wide enough to accommodate both an empty and loaded track; it is usually about 1400 ft. long and parallels the main haulage track. Thus these local gathering stations serve as partings for the main haulage road, which is kept clear for through traffic at all times. Each of these partings is in charge of a parting boss who is under the supervision of a motor boss. The duty of the parting boss is to see that the empty cars are apportioned to the different motors of his section and that they are ready at the partings for the motors. He sees that the coal is hauled off the partings promptly so that there is no congestion of cars. In general he performs the duties of an assistant motor boss.

Various types of gathering motors are in use at the Vesta mines, some special motors being employed for specific purposes. For example, in sections where pillars are being robbed (locally called rib workings) the tracks run across the ends of the pillars, necessitating some sharp curves. Motors with a short wheel base are used for this work; also, motors with low frames are used in sections where the bottom has heaved or creep has occurred, leaving a low top.

All the entries have trolley wires, and when a gathering motor is about to enter a room, a copper hook on the end of the motor cable is hung on to the entry trolley. The motorman fastens the trolley pole down to the motor frame. Steel rails are used entirely and act as the return circuit from the room face. On the face entries the track rails are connected to copper cables which act as the return circuit to the power house. The track rails in the rooms are not bonded but depend on the fishplates connecting the rails to carry the return circuit. All rails on entries throughout the mine are bonded with copper connections. Two men form a motor crew—a motorman and a snapper—the latter coupling and uncoupling cars, attending to hand brakes and throwing switches.

The motors have a trolley pole on each side, various sections of the mine having the trolley wire on that side of the track best suited to local conditions. A clearance space of 2½ ft. is left between the cars and the rib of the entry on the side of the entry opposite the trolley wire. The wheels of all the motors are outside the motor frame, but they are protected by suitable frame construction against damage from accidents. Anyone who has had to do with a derailed motor appreciates how much easier it is to place rerailing devices under outside wheels than under those of the inside type.

All room switches have bridles on the latches, which are thrown with levers. The switch points are held in position by a weight on the lever. This lever may also be installed so as to act as an automatic switch for a car coming out of a room onto the entry.

In gathering cars from a panel of rooms the following method is adopted. The motorman runs the trip of empties into a nearby vacant room and leaves it there while he pulls the loads out of all the rooms. Starting at the inby end of the entry the loaded car is pulled out of each room in turn and left standing on the entry at the room until all the loads are out of the rooms. The motorman then shoves the loads up the entry toward the face until they clear the last room inby, the snapper meanwhile coupling them together as they move up the entry. He then backs the trip of empties into each room, starting at the outby room, and leaves the end car in each room.

In case pillars are being drawn on an entry and

no empty track is available in a vacant room, then the cars are changed differently. Commencing at the outby end of the entry, an empty car is left in each room neck. Then the motor starts at the last room inby and pushes the empty car to the room face, where it is coupled up to the loaded car. The two cars are now pulled out to the entry and the load left on the entry just inby of the room while the empty car is pushed up the room again to the face and left there to be loaded. This operation is repeated at each room in the panel. Then the loads are coupled up and moved to the nearest parting or gathering station. One motor gathers the coal from all the rooms on a butt entry and three to six motors collect the loads for each gathering station.

All coal in the Vesta No. 4 mine is brought from the face to the central gathering station by electric motors; from the central station to the tipple the transportation is by wire tailrope haulage over a single track road of 90-lb. steel rails. The entire output of the mine passes over this haulage or dilley road—coal as well as slate. This road also is provided with a trolley wire and is equipped for motor haulage. With the exception of some pillar work, no coal is being mined along the rope haulage road.

The rope haulage road underground follows the coal seam for about 4 miles of its length. Halfway, or about two miles from each end of this mine section, a gully cuts out the coal seam and the road is carried across from one hill to another by a steel bridge, shown in Fig. 3. The rope haulage engines and boiler plant are situated in this gully. The rope haulage is divided into two sections at this power house, one unit pulling the coal from the central gathering station as far as the power house, another unit handling it from here to the tipple. Each unit is independent, both as regards engines and boilers; both outfits are in the same building but in different rooms.

Each haulage engine in the power house (Fig. 3) carries on its drums 2200 ft. of 1-in. tailrope and 1100 ft. of 1⅛-in. headrope. The coal is pulled from the central station in the mine to the power house by a 3500-hp., 52 x 60-in. engine built by the Vulcan Iron Works, of Wilkes-Barre, Penn. It is probably the largest mine haulage engine in the United States. A 1000-hp. 25 x 48-in. engine handles the trips of cars from the power house to the tipple. A round trip on the dilley road is about 9 miles, and the run is made in from 17 to 22 min. when hauling coal. This includes the time required for making the four stops at the power house necessary to change the ropes from one haulage unit to the other. To make the trip in the time noted requires running at express train speed on some parts of the road. A good track and road bed are absolutely essential. As a matter of fact a wreck on the dilley road is practically unknown unless the haulage rope breaks, or cars get away from the partings without a rope coupled to them.

In operation each trip carries a rider who signals the engine room when necessary by means of two light galvanized wires alongside the track. A piece of copper held against these wires closes the circuit and gives the signal. At regular signaling points a switch is used for this purpose. Signaling apparatus in the engine rooms includes both a bell and a gong, and two sets of these signals are installed at each engine; if one set gets out of order the other set is thrown in circuit by means of a switch. Current for these signal wires is furnished by miniature dynamos.

FIG. 3. POWER HOUSE AND TRESTLE CONNECTING HILLS NOS. 2 AND 3

Electrical power for the mine is furnished by three 750-hp., cross-compound engines operating generators delivering current at 550 volts. Eight Babcock & Wilcox stokers are used to fire the boilers in the large haulage unit and four of the same type of stokers are used on the other unit. The boiler-house coal is delivered by the rope haulage road. The dilley road passes under the roof of the boiler house and over the boilers. Cars with coal for the boilers are switched to a 1000-ft. sidetrack at the power house, where they are weighed. Then the coal is crushed preparatory to feeding it to the stokers; it is handled by rubber belt conveyors.

The dilley road is divided into four sections, each of which is inspected by a track walker before the man-trip runs over it in the morning. During the day these four men replace rope rollers and sheaves; the

FIG. 4. BRIDGE AND HAULAGE ROAD ENTERING HILL NO. 3

former carry the rope between the rails and the latter carry the return rope alongside the track. Miners and other employees are carried to work in the morning on the man-trip by rope haulage to the central gathering station in the mine, where the man-trip is split into three parts and each trip is hauled by a motor over the main haulage roads of the mine. There is an entrance to the workings at the end of the rope haulage system by which miners from the surrounding villages enter and get on one of these man-trips. The man-trips stop at the different face entries to allow the miners to get off at the nearest point to their work. In the evening the miners are collected and hauled out of the mine. The track grade is light and the danger of accident is reduced to a minimum.

The central gathering station is connected to the tipple by a trunk line of single track, of 90-lb. rail. Eight miles of 90-lb. steel rails are used on the main haulage roads; the entries are laid with 50-lb. rail and the room tracks have 30-lb. rail. Wood ties are used. The mine has about 300 miles of track—175 miles in entries and 125 in rooms. When a room is finished or temporarily abandoned the track is removed. Few ties are used in rooms, the following plan being adopted: As the mining machines leave some bottom coal, channels are cut in it, the track rails are placed in these channels and connected with fishplates. This makes a firm even bed for the rails, track is prevented from spreading as the rails are held in position by the channel, and they are prevented from turning by ties placed at intervals, say at the end of machine cuts.

Ties are necessary at curves in rooms—for example, around the ends of pillars or in case track is carried into side cuts; here the motor would tend to pull the track out of alignment. Track rails are easily pulled out from under a roof fall; a short length of strong chain is used, being provided with a car coupling link at one end and a pair of fishplates bolted through the links in the other end. In removing a rail the fishplates on the chain are bolted to the exposed end of the rail and the other end coupled to an empty mine car; a motor then jerks out the rail. In this way several lengths of rail have been recovered from beneath a fall of rock.

In entries the inequalities of the bottom cause an uneven grade on tracks, unless provided for; the track is surfaced by raising low points with long blocks or wedges. This makes a firm and even road bed which is further secured by waste between the ties as ballast. No timbering which a runaway trip of cars might displace is used on the main haulage roads or on the dilley road. A large fully equipped motor repair shop and supply store room is situated about ¼ mile inby from the central gathering station. A second motor pit is being constructed nearly 4 miles inside this point at the innermost workings of the mine.

FIG. 5. ROPE HAULAGE ROAD AT VESTA NO. 4 PLANT
Left—Bridge between hills Nos. 1 and 2. Right—Portal to hill No. 1. Guard rails at the side protect the bridge and the masonry from runaway cars

The track gage is 48 in. A road boss under the mine foreman has general charge of all track and trackmen, together with their laborers. The trackmen, when working on an assistant foreman's section of the mine, usually take orders from the assistant foreman. The motormen report on forms the number of cars of coal, rock and bugdust hauled during the day. The number of cars in each trip is posted on a large blackboard at the central gathering station; this gives the total daily number of cars moved to the mine end of the rope haulage. At the power house, midway in the rope haulage system, the number of cars passing that point are posted on a blackboard. At the tipple an itemized count of the cars and the weight of each car is kept.

The mine cars at the Vesta No. 4 mine are mainly made of ¼-in. sheet steel and the wheels have roller bearings. Stiff, double spiral springs slipped over the end of the drawbar under the car tend to lessen the strain on the car in starting and stopping. Special types of cars are used in this mine for specific purposes, such as cars for handling reels of cable or trolley wire, cars for hauling sand, water and various kinds of equipment.

Flare-up in Baltimore Tunnel

Cause of Catastrophe Still Unknown, but Evidently Was Not Due to Electricity Passing Through the Drawbars of the Mine Cars

AT 6:35 A.M. on the morning of June 5 a trip of 13 wooden mine cars, hauled by an electric locomotive, started into the water level drift, known as the Baltimore Tunnel, at the Baltimore colliery of the Hudson Coal Co. Investigations to date seem to establish: (1) That there were approximately 150 men riding in the empty cars; (2) that there were 14 twenty-five pound cans of black powder in the trip.

The powder seems to have been placed in the cars as follows: Seven cans in the rear car, one can in the third car from the rear, five cans in the fourth car from the rear and one can which was found outside the trip along the rib about opposite the fourth car from the rear.

The trip had proceeded to a point where the locomotive on the head end was approximately 150 ft. inside the mouth of the tunnel, the rear car being from 15 to 20 ft. inside the mouth of the tunnel. At this point a tracklayer, walking out of the tunnel, shouted to the motor runner that the trolley wire at a point about 200 ft. further in the tunnel was loose from a hanger. The motor runner stopped his trip, disconnected the electric locomotive from the trip and ran in a distance of about 250 ft. beyond where he left the trip standing and about 50 ft. inside the point where the trolley was loose from the hanger. He had about reached this point, stopped his locomotive and got off. Looking back he saw a flash in the trip. In some manner, not yet actually determined, the powder in the fourth car from the rear became ignited and in turn ignited the powder in the third car. After the ignition had taken place most of the men who were in the forward cars rushed back toward the mouth of the tunnel and, coming in contact with the flames and products of combustion by the powder, were either killed by burning or suffocation.

The total number of men who were killed or have since died in the hospitals is 91. The injured in the hospitals number 43, with a possibility of one or two of these men not recovering.

In August, 1918, a number of the men employed at Baltimore Tunnel refused to go to work because the foreman would not grant them an empty trip to go into the workings, the rules being that the men must walk in with their explosives. Some of the working faces to which these men had to walk were 2½ miles from the mouth of the tunnel, the large percentage of them being over a mile from the mouth. The morning on which they refused to work, Mr. O'Hara, the mine foreman, and Mr. McCrystle, the assistant colliery superintendent, met the men and persuaded them to go to work and stated that they would meet the mine grievance committee in relation to the matter. The men, from time to time, had been in the habit, instead of walking to their working places to go as far as the inside of the tunnel and wait until an empty trip would go in, at which time they would "jump" the trip and ride in. This practice was difficult of detection and extremely hard to stop. Mr. O'Hara and Mr. McCrystle, after considering the whole matter, decided that in their judgment it would be safer to grant the request of the men for an empty trip at 6:30 a.m. each morning if the men on the mine committee would in turn agree that no powder should be carried except in the last car of the trip, and that no men should ride in either the last car or the car next to it. At the meeting with the mine committee this was agreed to, with a further provision that the mine committee would each morning check up the trip to see that each and every term of the agreement would be carried out. The mine foreman and assistant mine foremen from time to time checked up the trip and found the rule being obeyed, but on this particular morning the mine foreman was about 1000 ft. from the drift on his way to the office from his home when the trip went in.

The seven cans of powder in the rear car were not burned or exploded and were taken from the car intact after the accident.

First Meeting of Coal Mining Electricians and Mechanics Institute

The first meeting of the Coal Mining Electricians and Mechanics Institute was held in the Y. M. C. A. auditorium at Charleston, W. Va., May 29 and 30, with about 300 in attendance. In spite of excessive heat and the fact that May 30 was a holiday, much interest was manifested and everyone stuck to the finish.

In all, eleven papers were presented, most of them illustrated with moving pictures or lantern slides. Considerable interest was shown by the audience in the various papers, as was evidenced by the many questions asked and the discussions that arose. The educational advantages of such meetings were made clearly apparent and many expressions of satisfaction were heard on the large amount of information, applicable to everyday work, that was derived.

It should be remembered that those present voluntarily gave up a holiday and attended this convention in order to secure knowledge that would be of benefit to themselves and their employers. This speaks volumes for their enthusiasm. That the exchange was a wise one was the consensus of opinion among those present.

Coal Pyrite Resources of Tennessee*

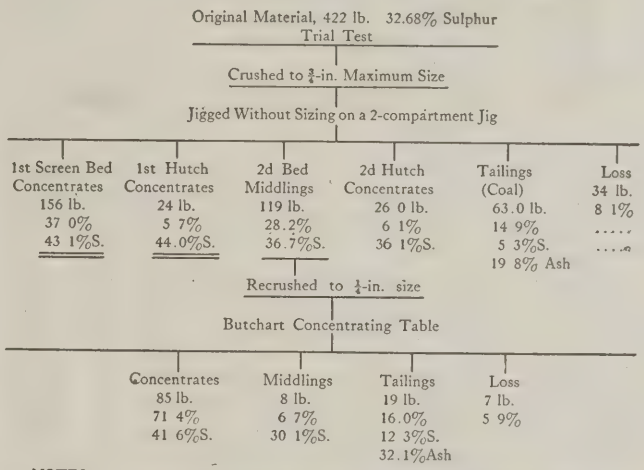
By E. A. Holbrook and Wilbur A. Nelson

SYNOPSIS—*Pyrite occurs in coal, usually in a more or less detached form. Experiments conducted upon certain Tennessee coal-mine refuse would indicate that such pyrite might be commercially extracted therefrom. The extraction plants would be simple and comparatively inexpensive.*

THE brassy-yellow mineral pyrite (FeS_2), a combination of iron and sulphur often known as "fools' gold," is of common occurrence in many kinds of rocks. Commercially it is important only as the basis for the manufacture of sulphuric acid, an acid essential in the manufacture of explosives, fertilizers and other chemical products. On roasting, the pyrite gives up its sulphur to form the gas, sulphur dioxide, which in turn is converted into sulphuric acid in large chambers, chiefly by the use of steam.

Formerly most of the pyrite used in the United States came from Spain, although some sulphuric acid was manufactured by burning or roasting pure native sulphur mined in Louisiana. At the beginning of the present war the Spanish supplies were cut off and it seemed essential, in view of the increased demand for sulphuric acid, to develop every available source of supply in this country. Many pyrite mines were opened in the Appalachian Mountains, especially in northern Georgia; and increased attention was given to the sulphur deposits in Louisiana and Texas.

It is well known to those engaged in coal mining that frequently balls and bands of pyrite occur with the coal, and this impurity must be removed before the coal is placed on the market. Because the coal in a mine contains pyrite balls or bands, however, does not mean that the product of this mine is high in sulphur, or inferior in quality, for often the contrary is true; that is, the sulphur, having concentrated into definite balls and bands, leaves the true coal comparatively free from sulphur.



Knowing that there were possible pyrite resources in certain of the coal mines in Tennessee, the State Geological Survey effected a coöperation with the United States Bureau of Mines, by which a survey of the pyrite in Tennessee coal mines has been made, and favorable material has been tested in the laboratory used by the Bureau of Mines at Urbana, Illinois.

At the present time (October, 1918) it appears that the great demand for pyrite has been met, partly by an unexpectedly favorable development of new sulphur resources in Louisiana and Texas, and partly by development of pyrite mines in the Appalachian Region and in Canada. Also it has not been considered opportune to interfere in any way with the production of coal. For these reasons the demand for coal pyrite has not been as great as was expected earlier in the year. However the supply known to be available constitutes a great reserve in time of need, and calls attention to a potential resource for the future.

This report outlines the known coal pyrite resources of Tennessee and details tests made at Urbana, Ill., on crude pyrite from the mines of the Bon Air Coal and Iron Corporation, to learn if the material could be mechanically treated to produce a pyrite of commercial purity.

Outside of the large deposits of pyrite and pyrrhotite in east Tennessee in the Ducktown region, the state has an additional source of pyrite from certain of the coal seams of the Cumberland Plateau.

The mines in the Bon Air-Clifty district all contain pyrite in the form of bands, nodules and kidneys, which are easily separated from the coal and can be recovered as a byproduct. It is estimated that the amount of

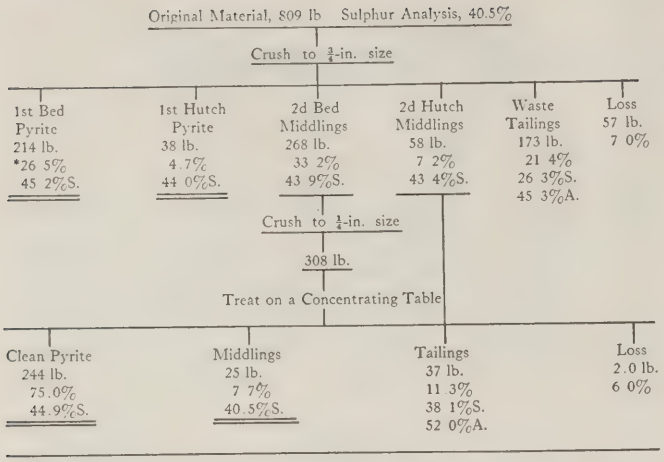
NOTES.—1st Screen Bed Concentrated means the coarse concentrates saved on the 1st bed of the jig.

2d Hutch Concentrates means the fine concentrates passing through this screen and saved at the bottom of the jig.

Middlings means a product of pieces containing part coal and part pyrite which have to be crushed finer before any separation of clean pyrite can be made.

FIG. 1. FLOW SHEET OF COAL PYRITE CONCENTRATION MATERIAL FROM EASTLAND MINE

pyrite, if all is recovered, from the mines in this district when operating at full capacity will be at least 50 tons daily. This estimate was made to include all the mines operating on the Bon Air branch of the Nashville, Chattanooga & St. Louis Railway.



Clean samples of pyrite from some of these mines gave the following analyses:

Carola Shaft, Bon Air, Tenn.	47.0 per cent. sulphur
Braeburn Mine, Eastland, Tenn.	47.6 per cent. sulphur
Ravenscroft Mine, Ravenscroft, Tenn.	46.4 per cent. sulphur

The mines on the Monterey branch of the Tennessee Central contain pyrite in a recoverable form. This pyrite is similar to that from the Bon Air district, on which tests were made. It is estimated that probably 40 tons of pyrite a day could be recovered from this district. Clean samples of pyrite were taken from some of these mines, which gave the following analyses:

Fentress Coal Co., Wilder, Tenn.	46.4 per cent. sulphur
Peacock Mine, Big Mountain Coal Co., Obey City, Tenn., Weather surface pyrite	46.1 per cent. sulphur

*Article published in "The Resources of Tennessee," Vol. IX, No. 1. It is based on an inquiry made by the Tennessee Geological Survey in Coöperation with the Bureau of Mines, through the Middle West Station of the latter, located at Urbana, Illinois.

*26 5% means that 26.5 per cent by weight of the original material was saved here.

FIG. 2. MINE REFUSE FROM RAVENSCROFT OPERATION OF BON AIR COAL AND IRON CORPORATION

Hand cobbed samples of pyrite were taken from these mines, so as to show the approximate percentage of sulphur in carload lots of unwashed pyrite as it would be shipped from the mines if no plant for treating the pyrite was installed. The following analyses show these results:

Carola Shaft, Bon Air, Tenn.	43.88 per cent. sulphur
Braeburn Mine, Eastland, Tenn.	46.40 per cent. sulphur
Ravenscroft Mine, Ravenscroft, Tenn.	43.72 per cent. sulphur
Clifty Mines, Clifty, Tenn.	42.72 per cent. sulphur
Fentress Coal Co., Wilder, Tenn.	45.08 per cent. sulphur
Peacock Mine, Big Mountain Coal Co., Obey City, Tenn.	40.36 per cent. sulphur
Brier Hill Collieries, Crawford, Tenn.	36.08 per cent. sulphur

The pyrite from the Fentress Coal Co. has been shipped to an acid manufacturer for some time, with satisfactory results to both the mine owners and the acid makers. The pyrite from all these mines, with the probable exception of the Brier Hill collieries, would be satisfactory for acid making after having been crushed and cleaned.

Pyrite is also found in a few of the mines in the Tracy City-Coalmont district, but not in sufficient quantities to justify saving and shipping. In the northeastern Tennessee coal field some pyrite occurs but no detailed investigation was made of this area.

Tests Made at Urbana, Illinois

About Sept. 1, 1918, two shipments of crude coal pyrite were received at the laboratory of the U. S. Bureau of Mines, University of Illinois, Urbana, Ill., from the Eastland and Ravenscroft mines of the Bon Air Coal and Iron Corporation, of Bon Air, Tenn. The possibilities of utilization of coal pyrite on a large scale for the manufacture of sulphuric acid made it desirable to conduct tests on this material to learn if mechanical crushing and washing would produce a high-grade commercial pyrite free from coal and other impurities and with possibly clean coal as a byproduct. The report following gives an outline of the final tests, together with a flow-sheet outlining a possible method of mechanically treating these materials.

This lot, about 500 lb. of crude coal pyrite marked from the Eastland mine, consisted of lenses of pyrite up to 10 in. in width and 4 in. in thickness, together with considerable adhering coal. To the eye, about 50 per cent. of the lumps by volume was pyrite and the remainder was coal.

Preliminary tests showed that the clean pyrite in the material was high grade, and that crushing to about 1-in. size would produce a clean pyrite concentrate, and consequently fairly clean coal as a byproduct. During crushing, a comparatively small amount of pyrite fines was produced, and therefore the largest sizes were the richest in pyrite. In other words, this coal pyrite, unlike the usual pyrite mineral, is stony and amorphous in structure and does not slime on crushing. This very important point made it possible to recover most of the pyrite by jigging alone, and the concentrating table was necessary only in treating the recrushed middlings. Even this product might be fed into the jig and saved as a hutch product, providing the capacity of the jig was ample.

The accompanying quantity flow-sheet (Fig. 1) shows the results of the final test run on the pyrite from the Eastland mine. Four hundred and twenty-two pounds were crushed to ¾-in. size in a gyratory crusher followed by rolls. This was jigged in a two-compartment Harz jig with ¼-in. screen beds. The coarse concentrates were saved as a screen-bed product and the fine concentrates were saved as a hutch product. The second screen-bed product contained some coal adhering to the pyrite and was a true middling product. It was therefore crushed through a ¼-in. screen and treated on a Butchart concentrating table. The table cleaned this product and produced a high-grade concentrate.

The crude coal pyrite from the Ravenscroft mine was of about the same physical appearance as the material from the Eastland mine[1]. Some of the lenses, however, were of rather light weight and had a peculiar gray color. To the eye it appeared about 75 per cent. pyrite by volume while the remainder was adhering coal. This material was tested in a preliminary way and the tests indicated that the same treatment could be used as with the material from the Eastland mine. This is a point of importance, because in any concentrating plant it would allow indiscriminate mixing of the material from the various mines before treatment. On crushing, the crude pyrite produced only a small percentage of fines, and it appeared that in regular practice, crushing to 1 in. round hole size would be sufficient before attempting concentration.

TABLE I. RESUME OF RUN OF EASTLAND MINE, BON AIR COAL AND IRON CORPORATION

Total, 422 lb.; 32.7 per cent. sulphur

Product	Concentrates Analysis Sulphur, Weight	Per Cent.	Middlings Analysis Sulphur, Weight	Per Cent.	Tailings Coal Analysis, Weight	Per Cent.	Loss

Table loss	...	....	..	....	..	.....	7
Totals	265	42.7	34	34.7	82	6.9S. 22.6A.	41

Practically 265 lb. of commercial pyrite was recovered, or 62.8 per cent. of the total material treated. On further treatment, the 34 lb. of middlings could be expected to yield 25 lb. of commercial pyrite, making a total recovery of 290 lb. of pyrite or 68.7 per cent. The coal tailings were 82 lb. or 19.4 per cent. The treatment loss was 41 lb., or 9.7 per cent.

[1]The pyrite which occurs in the mines on the Monterey branch of the Tennessee Central R.R. has the same physical appearance, and it is thought could be prepared for market in a similar way to the pyrite tested.—Wilbur A. Nelson.

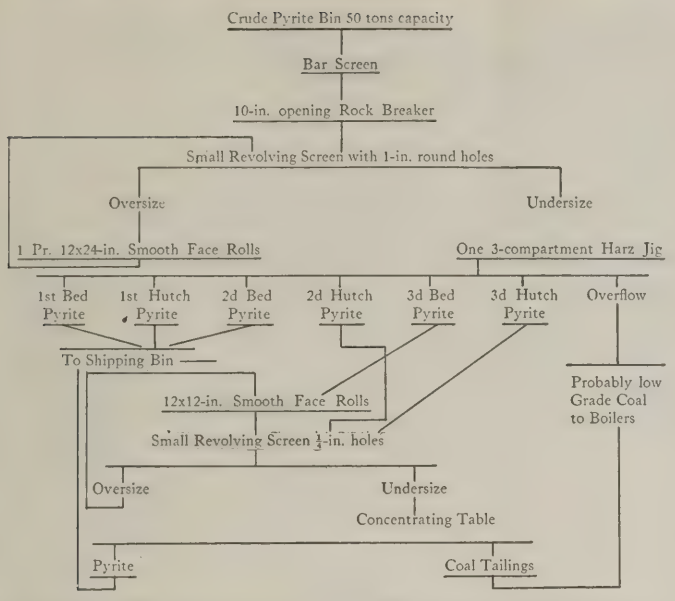

FIG. 3. FLOW SHEET OF 50-TON PYRITE CONCENTRATING PLANT FOR BON AIR-CLIFTY DISTRICT

The accompanying flow-sheet (Fig. 2) shows the final test treatment of the crude pyrite, together with the products, their quantity and analysis. The résumé sheet (Table II) shows the various products and gives an idea of what might be accomplished in percentage of recovery, etc., in a commercial plant.

The material from both the Eastland and Ravenscroft mines is high-grade pyrite with only a small percentage of attached coal. There is no technical difficulty in crushing it to about 1-in. size and, by jigging alone, to save nearly all the contained pyrite in a pure form. While the coal can be recovered in a size and purity such that it can be used as ordinary coal of screening size, yet if most of the pyrite contained as little coal as that sent for testing, it is not commercially important to save and clean the small amount of coal produced.

TABLE II. RÉSUMÉ OF TEST ON PYRITE FROM BON AIR COAL AND IRON CORPORATION, RAVENSCROFT, TENNESSEE

Weight, less sample, 790 lb.

Product	Pyrite Recovered Weight	Pyrite Recovered Sulphur Analysis Per Cent.	Middlings Weight	Middlings Sulphur Analysis	Coal Tailings or Refuse Weight	Coal Tailings or Refuse Analysis Per Cent.	Losses

Table loss	...	....	...	....	...	.....	2
Totals	521	44.7	...	....	210	28.4S. 46.5A.	59

From 790 lb. treated, 521 lb. of pyrite was recovered, analyzing 44.7 per cent. sulphur. This is a recovery of 66 per cent. The middlings were fine enough to be included in this pyrite column.

The coal tailings were 210 lb., or 26.6 per cent. of the original material. They analyzed 28.4 per cent. sulphur and 45.6 per cent. ash. This material is useless for coal on account of its high sulphur and ash content. Technically, there would be no difficulty in crushing this material finer and in extracting some of the remaining pyrite.

The treatment losses were 59 lb. or 7.4 per cent.

The concentrating table is recommended only as an auxiliary machine to clean the middling products. For a small plant the recrushed middlings could be fed back to the jig and a concentrating table dispensed with. However, this plan lessens the capacity of the jig.

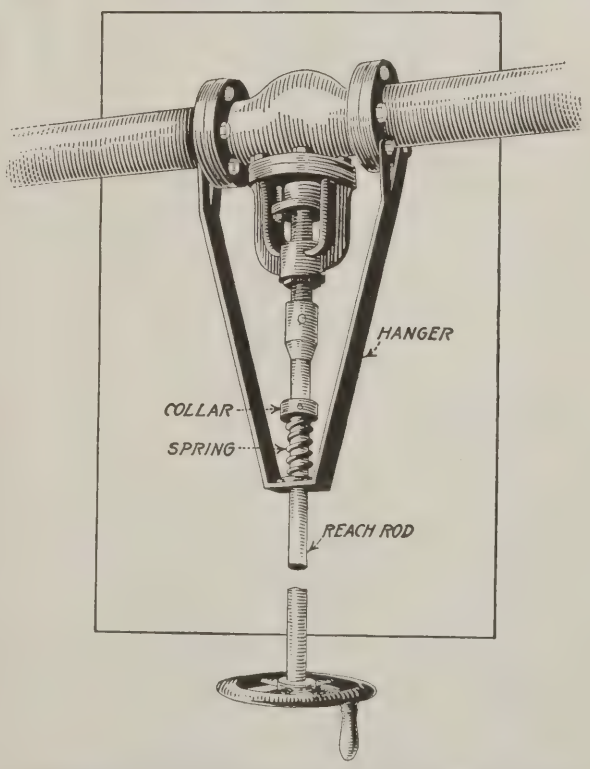

Fig. 3 is a flow-sheet of a proposed concentrating plant for the crude pyrite from these mines based on an estimated treatment capacity of 50 tons per eight-hour day. It should be remembered that on account of the low value per ton of the pyrite it is necessary to keep a treatment plant as simple as possible, and that while better recoveries might be made with a more complicated plant, yet from the test it does not seem advisable to install expensive apparatus necessary if the small sizes were to receive special treatment. Moreover, the coal pyrite slimes but little on crushing, and the small sizes are the lowest in pyrite content.

As a preliminary estimate, a plant to treat 50 tons per eight-hour day of crude pyrite should have crushing machinery consisting of a common Blake or gyratory rock crusher, followed by a pair of smooth rolls. This should be followed by a three-compartment plunger jig having compartments about 2 ft. square. Following this jig should be a pair of small rolls for recrushing the partly cleaned middling products from the jigs, and following these rolls should be a concentrating table for saving pyrite from the crushed material.

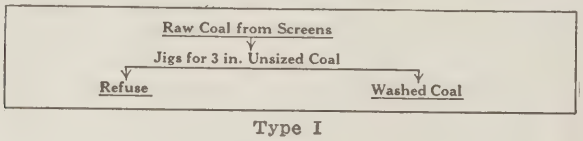
The necessary power, building, water supply and bins would probably bring the total cost of a pyrite concentrating plant up to about $14,000 at the present time. For a 100-ton plant per eight-hour day the total cost would be about $20,000.

Valve Reach-Rod Support

Nine out of ten reach rods that are used to operate overhead valves have either a poor bracket support or none at all, simply being pinned to the valve stem. In the accompanying illustration is shown a good way to support valve reach rods. A suitable light-weight hanger is bolted to the valve flanges. A spring placed under a collar on the rod on this hanger, as indicated, takes the weight of the rod. A support like this prevents wear on the threads of the valve stem.

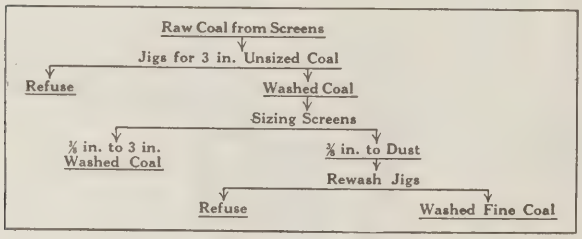
METHOD OF SUPPORTING VALVE REACH ROD

Preparation of Bituminous Coal—IV



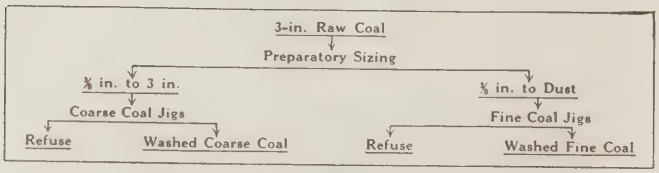
By Ernst Prochaska
Benton, Illinois

SYNOPSIS—*Many types and sizes of jigs as well as washing plants have been developed. The size of jig screen, the comparative size of plunger, the length of plunger stroke, the rapidity of stroke and the thickness of jigging bed, if any, are all factors that influence the efficiency attainable in the washing of any given kind and size of coal.*



BESIDES the character of the raw coal, which represents the base upon which the washing of the coal must be established, the type of the preparatory methods to be chosen must be considered. The rules for the proper selection of these methods have been given in a previous installment of this article. They are in close relation with the mechanical equipment of the jigs. According to the preparatory processes and the construction of the jigs, several main types of plant can be established. These are shown in the accompanying flow sheets.

In regard to the flow sheets shown, the following remarks may be made: The system of rewashing according to Type IV can in some instances also be used when the character of the raw coal itself does not require such rewashing. But when it is desirable to be independent of the human factor and the continuous care of the operator, especially when the washed coal must be exceedingly clean and is sold under strict specifications, the coal is washed very closely in the primary jigs and the resulting unavoidable loss of good coal in the refuse is recovered in the rewash jigs.



In Type VI the rewash jigs for the middle products of the primary jigs could be located ahead of the recrushing plant. This transposition should also be considered in Type V, and its advisability will depend much

Type VIII

FLOW SHEETS OF SEVERAL MAIN TYPES OF PREPARATION PLANTS

Type I—Easily washed coal, impurities not disseminated. Type II—Impurities not disseminated in the coal; coarse coal easy, fine coal difficult to wash. Type III—Impurities not disseminated in the coal; coal not easily washed. Type IV—Coal difficult to wash; impurities not disseminated. Type V—Coal not easily washed; impurities partly disseminated. Type VI—Coal difficult to wash; impurities partly disseminated. Type VII—Coking coal not easy to wash; impurities not disseminated. Type VIII—Coking coal easy to wash; impurities disseminated.

upon the character of the middle product. If this contains a considerable amount of slate, picking tables can be used for the purpose of removing the heavy, pure slate, which when crushed would interfere with the proper operation of the rewash jigs. The foregoing types can be changed to suit local conditions. Only the most typical cases have been selected.

The raw coal is fed to the jigs direct from the raw coal elevator if unsized coal is to be washed; and if the coal is sized before washing, from the discharge chutes of the screens either by means of gravity chutes or in sluiceways with water. This method, however, has been largely abandoned and modern washers have in the rear and above the jigs small equalizing bins to further secure an even and uninterrupted supply of

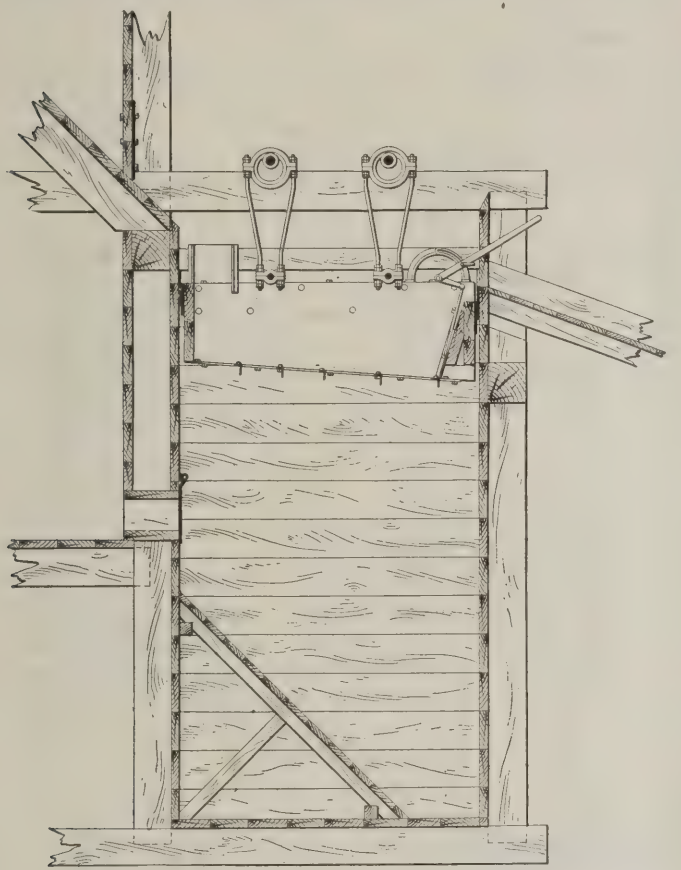

FIG. 2. STEWART JIG IN CONNECTION WITH JIG TANK

coal to the jigs. It is also advisable to feed the coal to the jigs by means of mechanically operated feeders. In most installations the flow of coal into the jigs is merely regulated by a slide gate. This, however, does not give an even feed, especially with coarse coal.

The simplest and best type of feeder is a slowly revolving drum with a slightly corrugated surface. The speed of the drum should be adjustable. This is accomplished most easily by means of a ratchet wheel and pawl, actuated from the jig eccentric shaft. Provision should be made whereby the pawl may be made to cover a greater or less number of teeth on the ratchet wheel so that the drum will revolve faster or slower as desired. Shaking or oscillating apron feeders are also in use, but these are more complicated, take up more room and cannot be adjusted with such nicety as the revolving drum feeders.

The coal from the feeders should flow into the jigs in such a way that it will be discharged below the surface of the water, so that all the coal is totally sub-

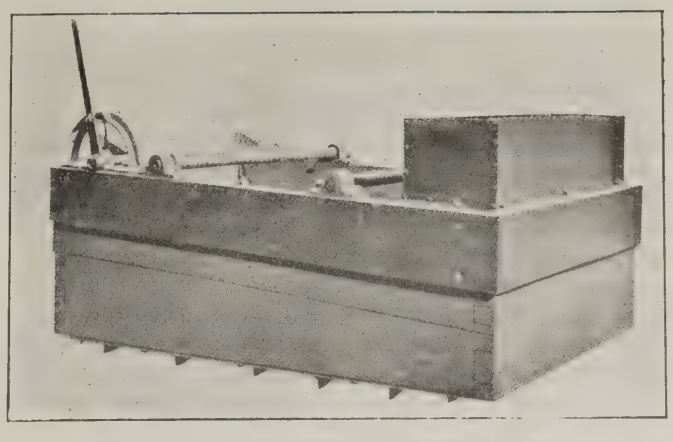

FIG. 3. SIDE VIEW OF STEWART JIG

merged. For fine and dry coal it is advisable to spray the coal before it enters the jigs, to prevent the formation of dry lumps.

It has been previously remarked that the construction of the jigs depends upon the character of the material to be washed. The jigs can be divided into three main types—coarse coal jigs, fine coal jigs, and jigs for unsized coal. According to the flow sheets, we find also jigs making only two products—that is, refuse and clean coal—and jigs making three products such as clean refuse, middle product and clean coal; or refuse, hutch work and clean coal.

Jigs can also be classified according to the means used to produce the pulsation of the water. Thus there are machines where the whole jig basket is moved up and down, and jigs with stationary screens in which the pulsation of the water is produced either by a plunger or by means of compressed air; or as in the Richard pulsator jig, by hydraulic shocks. The plungers can also be arranged differently. They may be located either in a separate compartment, which again can be placed in the rear of the jig compartment, or on one or both sides of the screens. We also have jigs with the plunger directly underneath the screen. One type of jig, with the plunger placed in a vertical position below the screen has, however, been proved a failure.

The jig screens are usually made of perforated steel plate; cast-iron grate bars are also sometimes used. The method of fastening the screen plates shows numerous variations. The methods used for refuse discharge are too numerous to mention, but they can be broadly divided into plain slide gates, either adjustable in a vertical position or swinging outward; double

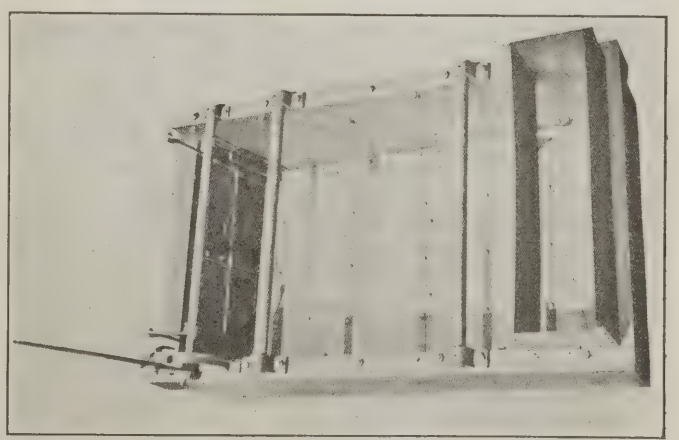

FIG. 4. TOP VIEW OF STEWART JIG, SHOWING SLATE GATE

gates, in which the lower gate regulates the height of bed and the upper gate regulates the outflow of refuse; revolving slate valves; kettles or pot valves and, finally, discharge of refuse through an artificial bed.

Furthermore, jigs can be classified as one, two or three compartment machines. If we consider that in addition to the differences mentioned in construction jigs can be built either of wood, steel plates, cast-iron plates or even of reinforced concrete, and that the plungers can be actuated by fixed or adjustable eccentrics or by means of crank-arm mechanisms, and that each single type of each group can be used without great changes in any other group, we get so many varieties that a systematic classification of the jigs into distinct types is almost impossible. By considering, however, so far as is feasible all the important differences, we can distinguish the following three general types:

Jigs with Fixed Screens—These include (a) coarse coal jigs, making two products only—refuse and washed coal. The plungers are in rear of the jigs, actuated either by fixed or adjustable eccentrics or by a crank-arm mechanism giving a differential motion. (b) Fine coal jigs with an artificial bed. These have the same plunger arrangement and drive as those of class (a). Refuse is withdrawn from the hutch and washed coal overflows at the front of the jig. (c) Coarse coal jigs with plungers underneath the screens. Either eccentric or crank-arm mechanisms are employed for giving the plunger motion. The refuse is discharged and the washed coal overflows. (d) Jigs with plungers on both sides of the screen. The plunger motion may be like that in type (a). These machines have either simple refuse and washed coal discharge or a third discharge for middle product. This type is chiefly constructed as two- or three-compartment jigs. (e) Jigs with one plunger between two compartments. This type is hardly ever used. (f) Jigs without plungers. The pulsation is actuated by puffs of compressed air or by hydraulic shocks.

Reciprocating Jigs or Jigs with Movable Screen—The construction of this type of jig does not show so many varieties as that of the fixed-screen type. Jigs of this type are used for unsized coal and make but two products. The only difference in the construction of the jigs is found in the arrangement of the slate gate and the methods used to diminish the suction on the upstroke. Fig. 2 shows the Stewart jig in connection with the jig tank. Fig. 3 shows the side view and Fig. 4 the top view, or rather bird's-eye view, of the jig basket. Fig. 5 shows the "American" jig. This machine is provided with adjustable wearing plates on the sides, securing a water-tight joint between the jig basket and the tank. The swinging slate gate, operated by the reciprocating motion of the jig basket, is opened at intervals but always to its fullest extent, in order to prevent the accumulation and jamming of large pieces of refuse in front of the gate. The interval between successive openings of the gate can be changed at the discretion of the operator. To obtain a closer regulation of the slate discharge, the operator can easily regulate the length of time the slate gate remains open. This is accomplished by means of a sliding cam which changes the time that the slate gate remains open by infinitesimal increments.

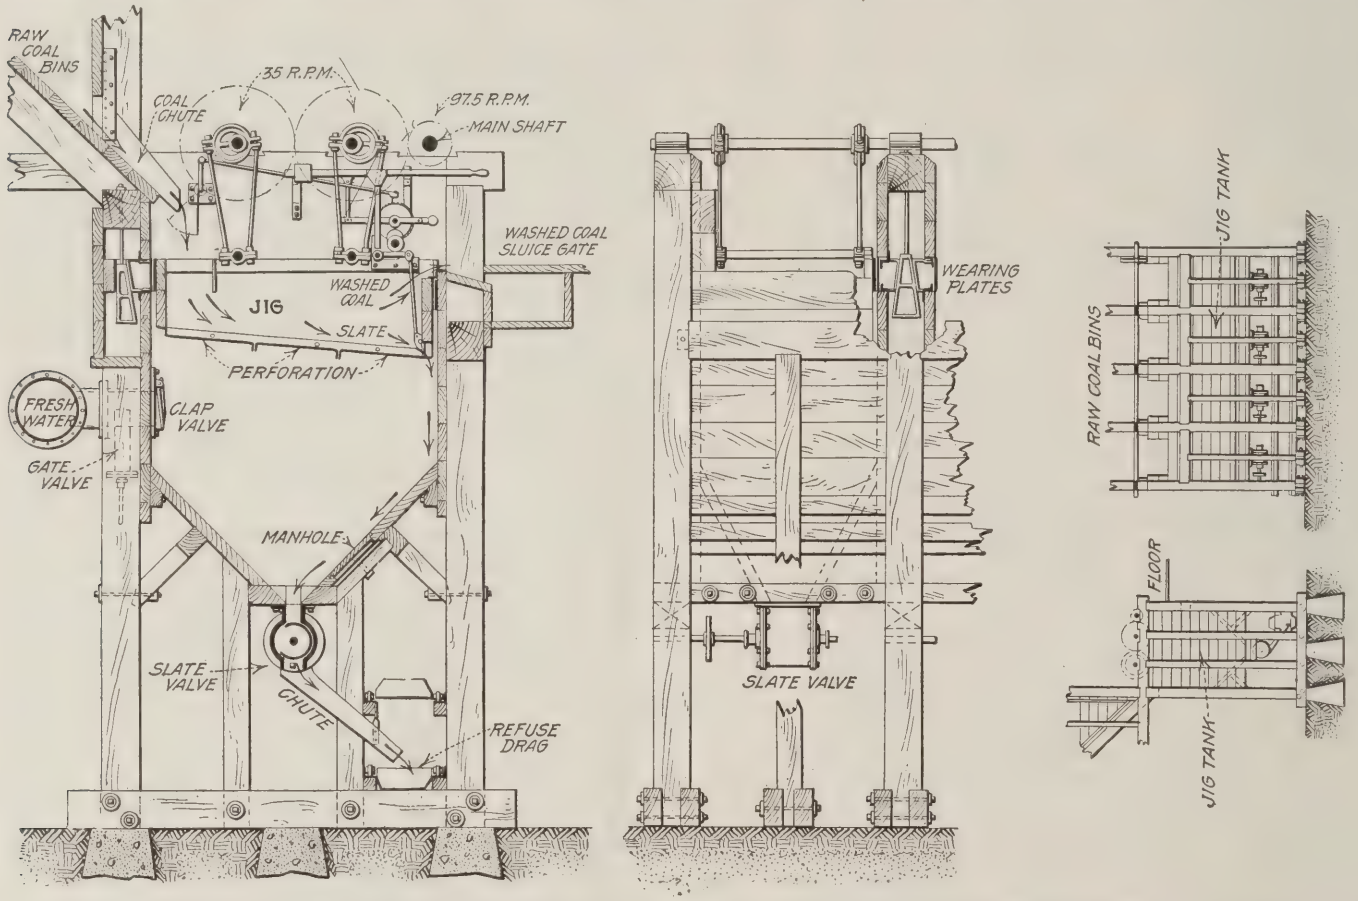

FIG. 5. SECTIONAL AND ELEVATIONAL VIEWS OF "AMERICAN" COAL JIG, SHOWING MECHANICAL DETAILS

Jigs with an Artificial Bed—This type is used only for fine coal, and the refuse is discharged through the perforations of the screen into the hutch. The difficulties of jigging increase with the fineness of the coal. The artificial bed is used to permit the discharge

of the refuse through the screen. A refuse discharge through a slotted opening or a gate would result in either too great a loss of good coal in the refuse or too much refuse would be carried over with the washed coal. Also, the small perforations in the screen required by the fineness of the materials would clog up easily and thereby nullify the pulsations.

In order to avoid all this trouble a screen is used with perforations somewhat larger than the largest size of material to be jigged. On top of this screen an artificial bed is laid, the material of which has a greater specific gravity than the refuse. The refuse finds its way through the interstices of the bed and drops into the hutch. The best material for an artificial bed has been found to be feldspar. For the first compartment feldspar between ¾ and 1¼ in. in size, and for the second compartment pieces that have passed through a 2¼-in. and over 1¼-in. round holes, is used. In some instances iron punchings or heavy slate have been used for a bed.

The discharge of the refuse is regulated in addition to the proper adjustment of the plunger stroke and speed, by the correct thickness of the bed and by using feldspar of a proper size. Both these values can only be determined by experiment. A deep bed consisting of small-size feldspar will give cleaner coal than a shallow bed made up of larger pieces.

Feldspar is especially well adapted for the purpose of making an artificial bed on account of its specific gravity, which lies between 2.5 and 2.6. On account of its hardness it resists abrasion, and being sharp-cornered makes a safe bed, permitting the small particles of refuse to pass through but keeping back the larger pieces of good coal. Slate being soft, wears off its sharp corners too easily and must be renewed frequently. Iron is too heavy a material and kills or at least weakens the pulsation of the water.

Fine-coal jigs are often arranged in tandem, forming in reality a two-compartment jig. This arrangement exposes the material to the jigging action during a longer period, but restricts the capacity. Fine-coal jigs show the same variations in regard to design, operating mechanism and materials used in their construction as the coarse coal jigs. Fig. 6 shows a fine-coal jig, with feldspar bed, built of timber.

On account of the novelty of the construction a description and illustration of a two-compartment jig for unsized coal will be given. This machine makes three products, and the pulsation of the water is produced by compressed air of 1½ to 2 lb. pressure per square inch. This reduces the moving parts to simple air valves located above the rear or water compartment of the jig. The construction of the air valve is shown in Fig. 7. Here *P* is the inlet port for the compressed air. The piston valve *V* is moved up and down by the eccentric drive *c*. In the highest position of the valve, as shown in the illustration, the air in the water compartment *b* can escape through the exhaust ports *R*. In the lowest position of the valve the compressed air enters through the port *P* and expands at first to some extent on account of the increase of area; but soon the pressure in the valve will be equal to the pressure in the supply pipe. The motion of the water is reversed on the exhaust stroke of the valve. The amount of air can be regulated by the length of stroke, the intensity of the pulsation by the pressure of the air, and the frequency of the pulsations by the speed of the eccentric shaft.

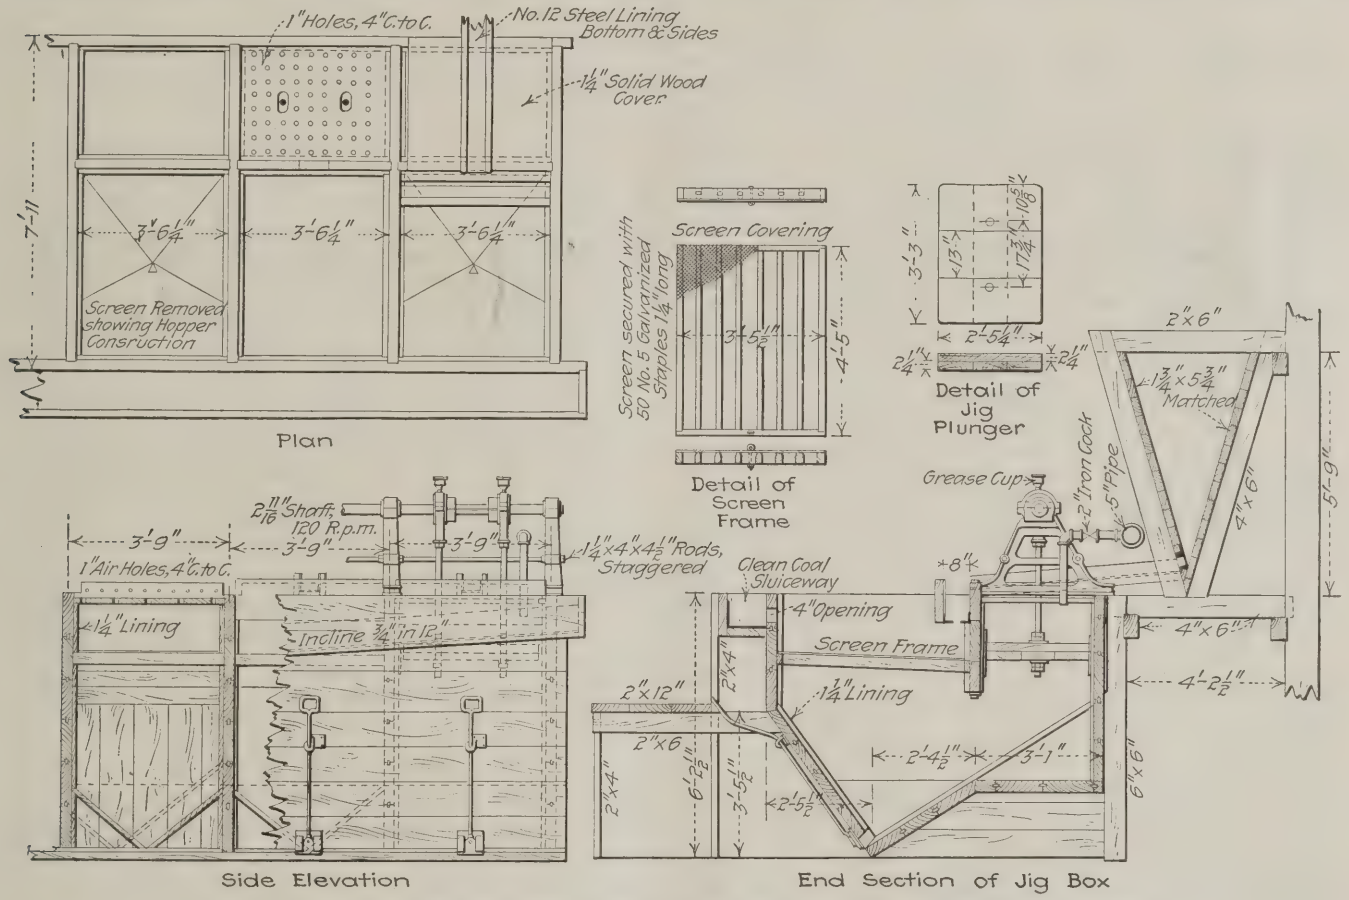

FIG. 6. DETAILS OF A FINE-COAL JIG, WITH FELDSPAR BED, BUILT OF TIMBER

The jig shown in Figs. 8 and 9 has two screens, *d* and *e*, both of which are slightly inclined against the direction of the flow of materials. The first and larger screen has three and the second or smaller one two air valves. The heavy slate is discharged immediately at the feed end of the jig through the slate gate *f* and falls through the chute *g* into the elevator *h*. This peculiar method of slate discharge prevents the disseminating of the soft and triturable refuse with the coal, and also prevents the choking up of the screen with heavy slate. On the second screen *e* the clean coal is separated and overflows at *i*. Light refuse or the middle product, according to the character of the coal, is discharged at *k* and falls through the chute *l* into the elevator pit *m*. The sludge and fine refuse which passes through the perforation of the screens is conveyed by means of a right- and left-hand screw conveyor *n1* and *n2* to the elevator pits *h* and *m*. The water is regulated at *p*.

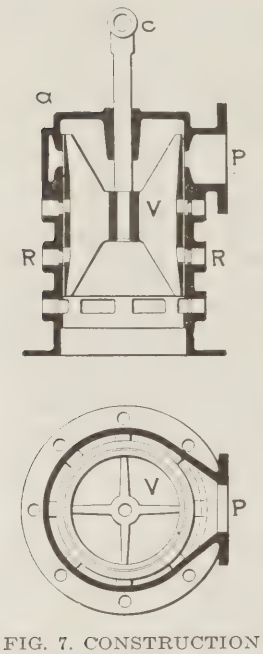

FIG. 7. CONSTRUCTION DETAILS OF AIR VALVE OF TWO-COMPARTMENT JIG

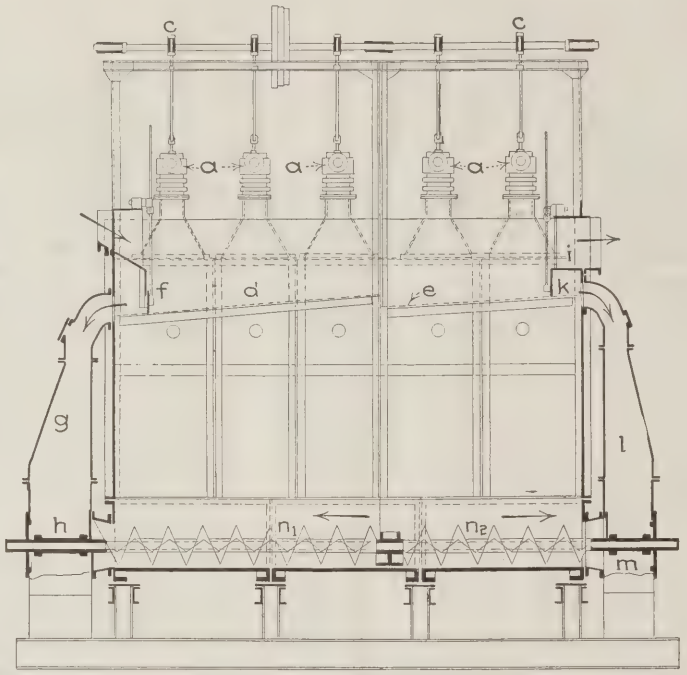

Fig. 8

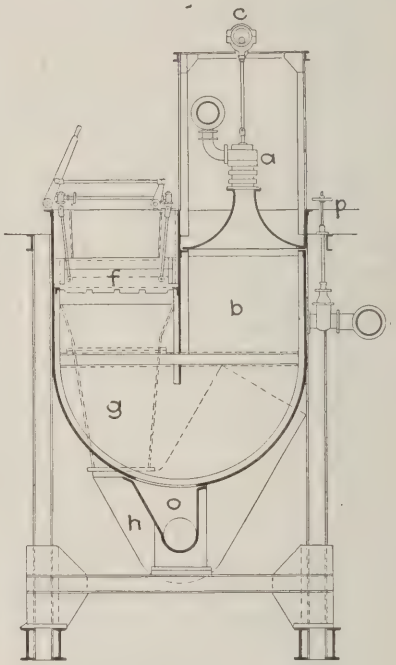

Fig. 9

FIGS. 8 AND 9. TWO-COMPARTMENT JIG FOR UNSIZED COAL

No fundamental difference exists between the method of operation of the jig described above and other machines. The peculiarity of the use of compressed air can be partly explained by the large size in which the jigs are built. But plunger-jigs also are built in equally large sizes for the treatment of unsized coal and are quite successful.

Owing to the great variety in the construction and arrangement of jigs, it is hardly possible to give authentic figures in regard to the work performed. This furthermore becomes more complicated, as the work and the output of a jig depend not only on the proper selection of certain dimensions such as length and width of jig screens, proportion between plunger and screen area, height of overflow above screen, and the size of perforations in the screen, but also on the proper regulation of the plunger stroke, speed of eccentric shaft, size of materials, thickness of bed, water supply and many other considerations.

The details of construction and the methods for securing a proper adjustment were developed by each builder of jigs independently and according to his own ideas. For these reasons we have a multiplicity of designs and data on operation which, however, give similar final results. In any case, however, the tabulation of the most important data for each type of jigs (see the table) requires some explanation.

The methods used will change the relation between the different factors independently of the capacity, which naturally influences the size of the jig. If coal is sized before washing, a series of small jigs will be required; whereas if unsized coal is to be treated, quite frequently one large coarse-coal jig will suffice. This will explain the considerable difference in the dimensions and the capacity of the jigs. The character and the size of coal on the one hand and the type of the jig on the other strongly influence the length of the plunger stroke. The number of strokes per minute must be increased in inverse proportion, and the length of the stroke in direct proportion to the size of the coal. That is, coarse coal requires a slower and longer stroke than fine coal, for which a short, quick pulsation is more advisable. The size of the perforation in the screen must be smaller than the smallest size of the coal. The big difference in the power consumption can be explained by the different sizes of the jigs.

Jigs for unsized coal are mainly built for great capac-

TABLE OF THE MOST IMPORTANT JIG DATA

	Coarse Coal Jigs	Unsized Coal Jigs	Fine Coal Jigs
Width of jig screen...	24 in. to 6 ft. 6 in.	30 in. to 6 ft. 6 in.	20 in. to 7 ft. 3 in.
Length of jig screen..	3 ft. 3 in. to 16 ft.	6 ft. 6 in. to 19 ft. 6 in.	6 ft. 6 in. to 21 ft. 4 in.
Capacity per hour in tons.....	5 to 150	30 to 150	5 to 70
Capacity per square foot of screen area in tons.....	0.4 to 1.0	0.8 to 1.5	0.3 to 0.5
Number of strokes per minute.....	20 to 100	35 to 110	100 to 200
Length of stroke in inches.....	1½ to 16	1¼ to 6	⅜ to 2
Proportion of area of plunger to screen area.....	0.7:1 to 1:3	1:2 to 1:2.5	1:1 to 1:1.5
Size of perforations in screen in inches...	⅛ to ½ in.	5/32 to ¾	⅜ to ½
Size of bed material in inches.....	.....	.....	9/16 to 1¼
Thickness of bed in inches.....	.....	.....	1¼ to 2½
Horsepower required.	1 to 6	3 to 7	1 to 5

ity. In some cases the whole amount of raw-coal screenings is put over one jig only, and I know of some machines treating 150 tons of raw coal per hour. The perforations in the screen are larger than in the screens of coarse-coal jigs, because a heavier pulsation is required to loosen up the unsized coal. This, however, will make the size of perforation in the screen larger than the size of the smallest particles of the material to be treated, and the refuse collecting on the screen must prevent the downward passage of the fine coal.

In addition to the foregoing considerations it is of great importance to determine the correct thickness of the artificial bed and the proper size of the material to be employed therefor. The data shown in the table can be used only as a guide. Different coals will require different beds.

(To be continued)

Coal in the Peace River District of British Columbia

By Robert Dunn
Victoria, B. C.

For years the Peace River country of the Canadian Northwest has been known to sportsmen as a bear hunters' Mecca. Within recent years, however, important discoveries of coal and other minerals have been made along the upper waters of this stream and its tributaries. Sergt. C. F. W. Rockfort, of the Canadian Engineers, recently returned from three years of active service overseas, after long search some years ago was rewarded by finding the outcroppings of several coal beds on the banks of Carbon Creek. He is a firm believer in the future of this region.

The Sergeant states: There are several outcroppings showing beds totaling nearly 100 ft. These beds vary in thickness in most cases from 3 to 6 ft., while six of the beds range between 5 and 7 ft. The series culminates in a vertical bed having an exposure of 15 ft. 9 in.

Samples were taken and analyses obtained from Thomas Haynes & Son, analytical chemists of Toronto, Ont., which are reported as follows:

	No. 1	No. 2
Moisture at 110 deg. C	4.07	0.93
Volatile hydrocarbon	23.31	38.51
Fixed carbon	71.28	59.12
Ash	1.34	1.44
	100.00	100.00
B.t.u.	13,693	15,313

It is confidently believed by the locater of this property that an improvement in quality will be proved by development, but as it stands he thinks it must be admitted that a field of fine bituminous coal, of which little is generally known, has been to an extent demonstrated. No. 2 sample indicates a high-class coking coal for smelting purposes according to the chemists entrusted with the analysis of the specimens. As no Canadian railroad is using better fuel, it is thought that the opening up of these deposits would furnish the Grand Trunk Pacific Ry. with a desirable source of supply for its western lines.

With reference to the railway situation, Sergeant Rockfort is looking forward to projected extensions of transportation facilities through the Peace River district to lead to the active development of the Carbon River coal deposits. His opinion, and that of most of the settlers in that territory, is that the continuation of the Pacific Great Eastern Ry., which now traverses the province from the tidewater terminus known as Squamish, situated on the lower mainland north of the City of Vancouver, to Chasm, which is 180 miles inland and generally in a northeasterly direction, is of vital importance to British Columbia. The road has been surveyed to the town of Prince George and some further construction work on the unfinished sections is to be undertaken this summer.

But those interested in the Great Northern district are not satisfied with the present program. They want the railroad carried north from Prince George through the Peace River Pass to tap the immense area beyond. The resources of this section embrace not only thousands of square miles of uncultivated lands, but promising oil possibilities as well as coal.

Legal Department

Injury Through Fall of Slate—In an action for fatal injury to a miner resulting from a fall of slate in an air course, testimony of an assistant state mining inspector that the air course was too wide, that the roof was not safe unless cross-timbered, and that the mine foreman had been so advised before the accident, was properly admitted as tending to show that the operator was negligent in permitting the dangerous condition to remain in the face of actual or constructive knowledge of its existence. The injured man did not assume the risk of the accident unless the peril was so manifest to him that an ordinarily prudent man would not have encountered it. (Kentucky Court of Appeals, Lay vs. Carter Coal Co., 206 Southwestern Reporter, 769.)

Organizing Coal Corporations—One who transfers to a corporation a lease of coal lands pursuant to a contract made with the promoters of the company and accepted by the corporation when organized, in consideration of a block of stock representing a one-fifth interest in the value of the mining property when equipped for production, is entitled under such contract to be treated as a subscriber for such stock, and may compel a transfer of the stock to him according to the agreement. In this case it is found that provision in the contract for a "one-fifth interest in the property fully equipped" is referable to equipment of the property with tipple, tracks, haulways, cars, and all necessary machinery and motive power to successfully operate the property. (West Virginia Supreme Court of Appeals, Wallace vs. Eclipse Pocahontas Coal Co., 98 Southeastern Reporter, 293.)

Enforcing Sales Agency Contracts—Plaintiff and defendant entered into an agreement whereby defendant, a coal-producing company, appointed plaintiff as its exclusive agent to market defendant's output, on condition that defendant would load first-class merchantable coal and ship same on plaintiff's orders, and that plaintiff should use his best endeavors to sell defendant's output at prevailing market prices, at a stated commission, etc. Held, that the contract was not invalid for want of mutuality as purporting to bind defendant without any reciprocal obligation on plaintiff's part. And where it appears under a contract of this kind that the producer's refusal to make deliveries would involve injury to the agent which could not be adequately compensated in damages, by reason of his inability to obtain coal of like quality elsewhere to supply his trade, a court will grant relief by injunction to restrain the producer from wrongfully breaking the agreement. (Kansas City Court of Appeals, Warren vs. Ray County Coal Co., 207 Southwestern Reporter, 883.)

Fusibility of Ash from Pennsylvania Coals*

Samples of Coal Tested Were Practically All Standard Mine Samples Gathered in Accordance with the Method Adopted by the Bureau of Mines—The Lower and Older Coals Contain More Refractory Ashes

By W. A. Selvig and A. C. Fieldner
Fuels Chemical Laboratory, U. S. Bureau of Mines, Pittsburgh, Penn.

PREVIOUS papers[1] gave a description of the standard gas-furnace method used by the Bureau of Mines in making ash-fusibility tests, a discussion of the relation of fusibility tests to clinker formation, and complete tables giving results obtained for West Virginia and the Interior Province coals. This paper includes a table giving the results obtained for the coals of Pennsylvania, which is by far the greatest coal-producing state in the Union.

The various coal beds of the bituminous coal field of Pennsylvania are arranged according to their geological succession, the uppermost beds being listed first. Under each bed the arrangement is alphabetical according to county, town and mine. The samples tested are practically all standard mine samples collected according to the methods used by the Bureau of Mines.[2] A few car samples which were considered representative of the output of the various mines were also included.

> FUSIBILITY of ash is one of the coming problems of the coal industry. Manufacturers are highly interested in the subject, but as yet the mine owner has regarded it with indifference and as a problem which gives him no concern. A coal with an ash of low fusing temperature is apt to give a bad performance because the fluxing of the ash may clog the grates and prevent the passage of air.

The various coal districts of the anthracite region are arranged alphabetically under the field to which they belong. Under each district the arrangement is (as before) alphabetical, according to county, town and mine. The samples tested are practically all delivery samples of the various sizes as marketed, only a few standard mine samples being represented.

The number of samples from each mine, the lowest, highest and average softening temperatures in deg. F., and the per cent. ash and sulphur in the dry coal are tabulated for each mine tested. Average values for each mine were computed from the individual samples, and from these values averages representing each bed or district were obtained. In some instances the average values given for the beds or districts represent only a few mines and are in such cases not truly representative.

The point taken as the softening temperature is that at which the ash when molded into solid triangular pyramids $\frac{3}{4}$-in. high and $\frac{1}{4}$-in. at the side of the base, and mounted in a vertical position, has fused down to a spherical lump. Samples remaining unfused at 3010 deg. F., which was the highest temperature attained in the test, were marked plus 3010 (+3010) and used as such in figuring the average values for the mine from which the average values of the beds or districts were computed.

As stated in a previous paper[1] on the fusibility of coal ash from the Interior Province coals, the softening temperature of coal ash from the various fields of the United States range in general from 1900 to 3100 deg. F. This range of softening temperature for convenience in discussion is subdivided into the three following groups: Class 1, refractory ashes, softening above 2600 deg. F. Class 2, ashes of medium fusibility, softening between 2200 and 2600 deg. F. Class 3, easily fusible ashes, softening below 2200 deg. F.

The softening temperature of the ash from the bituminous coal beds of Pennsylvania are found in Class 1 and Class 2, principally in the latter. The beds of the Monongahela, Conemaugh and Allegheny series, with the exception of the Lower Kittanning, Fulton and Brookville beds of the Allegheny series, are quite uniform as regards fusibility and come in Class 2. The Lower Kittanning bed of the Allegheny series contains a large number of mines which give ash of high fusibility and the average for this bed almost places it in the lower part of Class 1. The Fulton and Brookville beds of the Allegheny series, as also the Bloss bed of the Pottsville series, come in Class 1.

It is interesting to note that the coal beds which show high softening temperatures are geologically the lower and older beds of the bituminous coal field. This was also found to be true of the coal beds of West Virginia. It has been found that in general the beds of the Monongahela and Allegheny series of Pennsylvania give a more refractory ash than do the same beds found in West Virginia.

The ash from the anthracite region of Pennsylvania is highly refractory, coming in Class 1. The softening temperature in practically every instance is above 3000 deg. F.

The tables on the pages that follow show the fusing temperatures of the ash in the coal beds of Pennsylvania and the percentages of both ash and sulphur which the coals are found to contain.

Handy Uses for Old Pipe

By Charles H. Willey
Concord, N. H.

An adjustable long work support (or "old woman") for holding one end of bars, shafts, pipe, etc., while working on the other end in a vise or machine can easily be made from a length of 2-in. pipe, as shown in Fig. 1. The lower end of this pipe is split and spread apart, as indicated by the dotted lines, and a base of concrete molded around the anchors thus formed. A satisfactory mold can be made from an old bucket by removing its bottom and setting it bottom up on a board. The adjustment of height is provided for by the use of a Y- or U-bolt and a nut and large washer. These yokes are easily made by splitting the round body of the bolt in half for a certain distance and then bending to the desired shape.

FIGS. 1 TO 4. SOME PRACTICAL WAYS IN WHICH TO UTILIZE OLD PIPE

Fig. 2 shows how a useful set of skeleton wrenches can be made from short lengths of steel pipe. Select the size of pipe most suitable to the size of wrench desired. Split open one side of one end; open it out flat and cut to fit the nut. Much time can be saved by the use of such light-weight skeleton wrenches running on or off nuts that go a little too stiff to be turned with the hand.

Hacksaws are always being borrowed by somebody and lugged off. One day I made up several homemade frames such as shown in Fig. 3. They are simple to make, using $\frac{1}{2}$-in. pipe bent to the regular frame shape and flattened at *A* and *B*, fitted with a pin and a tightening bolt, and provided with a blade. When I loan these tools it does not deprive me of my good adjustable kind.

Often the hand wheels of various valves about the run of piping become lost, and if they cannot be found I replace them with T-handles made by flattening the center of a short piece of pipe and cutting a square hole through it, as shown in Fig. 4.

Both No. 4 and No. 5 anthracite buckwheat has been used successfully in briqueting. It has decidedly passed the stage of experimentation. Briqueting with this material is a commercial success in spite of the fact that the price of No. 5 buckwheat has gone up considerably on account of the increased demand for this size fuel. When culm can be cleaned successfully on a commercial scale it has a wide field of usefulness. This size of anthracite has been burned successfully by mixing one part of culm with two parts of good coking bituminous coal. A fire of this mixture can be burned successfully with a bed of fuel 16 to 20 in. thick, using natural draft. This mixture can also be used in a stoker much the same as when burning straight bituminous fuel.

Shall the Government Loan Mechanical Equipment to Technical Schools?

THE so-called Caldwell Bill, proposing to loan the Government's surplus machine tools, especially those adapted particularly to the manufacture of munitions that are now no longer needed, to the various technical institutions throughout the country, was reintroduced in the House of Representatives on May 26. This bill was introduced in the last Congress but failed to pass. Practically the only change in the present measure from its predecessor lies in the inclusion of "scientific instruments" as well as machine tools.

Unlike much legislation proposed and enacted, this measure is short and to the point. It reads as follows:

A Bill to provide for further educational facilities by requiring the War Department to loan certain machine tools and scientific instruments not in use for Government purposes to trade and technical schools and universities, and for other purposes.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, that the Secretary of War shall lend to trade and technical schools and universities and other recognized educational institutions which in the discretion of the Secretary of War should have such equipment the machine tools and scientific instruments suitable for their use which are owned by the United States of America, which are under the control of the War Department, and which are not being used for Government purposes: Provided, however, that each institution so equipped shall be responsible to the United States of America, under regulations to be prescribed by the Secretary of War, for the proper care and safe return of such equipment when demanded, ordinary wear and tear excepted.

It is a matter of common knowledge that the advent of the struggle just past (while there was absolutely no reasonable excuse therefor) "caught us napping." Our army, of course, was small, but in addition our arsenals were not only practically bare of modern weapons but, worst of all, adequate machinery for the manufacture of arms and ammunition in sufficient quantity was lacking. It takes time to build machine tools, particularly if they are of a special design adapted to a specific purpose. Fortunately, when war was declared many factories had been equipped for making munitions for various foreign governments, particularly England and Russia. After some compromising as to design, these plants were able to turn out a product that answered the purpose, although not exactly the product to be most desired. Thus many of our troops went overseas armed with the modified Enfield rifle instead of the Springfield.

The idea of loaning to colleges and universities the Government's special instruments and machine tools for which the country now has no pressing need, we believe is a good one and worthy of strong support. If it is enacted into law not only will educational institutions receive some much-needed equipment that will serve a valuable purpose in training future engineers, but these instruments and tools will yet remain the property of the Government and be subject to immediate call should a national necessity again arise.

We all hope that such a necessity may never come, yet we all realize its possibility. Should we then repeat the blunder of the past or would it be wiser to profit by bitter experience and be ready?

Friendship in Business

WHAT constitutes friendship in business? is a question that is more or less puzzling the selling end of the coal trade at the present moment. Does it really profit a man to play on the level with his customers in times of distress? or is it the better policy to throw all moral scruples to the winds and play the "game" for all it is worth, content in the knowledge that customers are as ready to forget a good turn as to overlook a scalping—if the latter is softened by honeyed explanations?

The time is now at hand when the conscientious coal man is hoping to reap his reward for pulling his various customers through the trying coal shortage of the past year. Still ringing in his ears are their voluble and emphatic assurances that they would remember him in the future if he but took care of them in their hour of need. And in the majority of cases the coal man did play the friend in need. But today he is questioning his judgment in so doing, and also doubting mankind in general.

Promises are not materializing, and it appears that instead of gaining his customers' confidence and good will the coal man has lost caste. There can be no denying that the coal people in the past few years have lost standing which it will be difficult to win back. If coal was sold at cost, the charge of being mercenary would still be laid at the coal man's door. In public opinion he is branded as an arch-pirate.

To what extent, then, can he rely upon the pretended or luke-warm friendship of his trade? The matter of price, on the whole, always interests the buyer most; and while the quality of the coal is also now considered with more care, nevertheless there remains a grave suspicion of the disparity in prices resulting because of this feature. The friendship of a customer in business, as it is commonly understood, is after all nothing more in substance than a card of entrée to the inner sanctum of the buyer. If it is valued at anything else, it is trying to realize on watered stock. So coal men are learning today—and bitterly, too.

Should friendship be eliminated from business? Assuredly not. Our conception should be changed, however, as to what constitutes business friendship. We have not yet learned to distinguish clearly between friendship in business and business friendship. The two terms are regarded as synonymous, and therein lies the germ of misunderstanding.

Friendship in business has already been defined: it is the card of entrée. Business friendship, on the other hand, is efficient service: a service such as the customer

will feel it unprofitable to dispense with. He will consider it as much a part of the purchase price as the actual material itself. When the customer is frankly willing to pay this premium, we have business friendship of a high order. And it is to this conception of friendship that all business must reconcile itself. The coal trade would do well to apply it more thoroughly and universally, and, perhaps, thereby earn a modicum of the public's favor.

Labor of Anthracite Mining

THE output per underground worker in the anthracite mines during 1918 was only three-quarters that of the underground workers in the bituminous mines. One would expect that the average relative price of anthracite and bituminous coal would be deducible from that proposition when the relative wage scale in the two regions was taken into account.

It is, however, not so, for the Pennsylvania anthracite regions employ 2⅓ times as many men outside per ton of coal mined as the bituminous regions in the same state. This larger employment of outside workers at the hard-coal mines largely accounts for the high cost of the fuel. The careful preparation given the products is largely the cause for the disproportion of surface employees.

The average employee in the anthracite region, including both underground and surface workers, handles only two-thirds as much coal as the average employee in the bituminous region of Pennsylvania. And it must be remembered that the coal-handling costs of Pennsylvania are higher than those of many states, owing to the fact that at Pennsylvania bituminous coal mines there are many long outside hauls. The large number of coke ovens and washeries also tends to increase the number of surface workers per ton of coal mined.

Otherwise the rates in the number of outside employees per ton produced in the anthracite and the bituminous regions would be still more marked.

Coal-Mine Accidents by Nationality

THE UNITED STATES Bureau of Mines and Albert H. Fay, its statistician, are to be congratulated in securing the record of fatalities and injuries by nationalities to be found in an article in our last issue. It will be noted how low is the fatality rate of Americans. Those of us who talk glibly about the carefulness of the English miner will be somewhat surprised to see how poor is his showing. The "reckless" Irishman, like the "reckless" American, has also a splendid record in the anthracite region for avoiding fatalities second only to the Tyroleans and Hungarians, who are always admirable workers from every point of view—efficiency, safety, reliability and good citizenship. The Irishman does however, carry the honors in the bituminous region of being the "most frequent deceased" of all the English-speaking group.

The Hungarian record accords with general experience. The people of that nationality are both frugal and careful. The Greek record is consistently bad from end to end, and all records are worse in West Virginia than even in the anthracite region of Pennsylvania, the mines of which are by no means as dangerous as commonly supposed, if fatality ratios are an indication. It must be remembered that the tables cover a period during which occurred the explosion of Layland No. 3 when 112 men were killed, and the accident at the Kempton plant of the Davis Coal and Coke Co. when 16 men lost their lives. Then followed the Barrackville explosion at Jamison No. 7 when 10 men were killed. All these explosions took place in West Virginia. Pennsylvania had during that time only the explosion at the Ernest mine of the Jefferson & Clearfield Coal and Iron Co. when 27 men lost their lives.

Accidents like these are no respectors of nationality, and being more numerous in West Virginia than in Pennsylvania, they run up the fatality record of that state. It would be interesting to know how the tables would look with catastrophic accidents of the kind mentioned excluded. Still the injury record suggests that the revision would not appreciably increase the safety status in West Virginia.

The argument in favor of increasing education among foreign mine workers advanced by the Bureau of Mines is worthy of careful consideration. An enumeration based on schedules of ability to read and write the English or other languages, and a careful tabulation of the accidents suffered by men of the different schedules, would be extremely interesting and might be well worthy of collection. We should surely know how large a proportion of our mining population is in need of elementary school training. The fatality and injury rate could easily be recorded on that basis when the educational status of all the men was once determined.

Mine Supply Accounting

THERE are undoubtedly some coal operators of the old school who look askance at the installation of any comprehensive system of accounting for mine supplies. The natural tendency is to view a matter of this kind as an expensive luxury, the results of which are not commensurate with the expenditure involved. However, no one can longer maintain such views who has looked into the matter carefully.

Modern mine accounting in general is so carefully handled in these days that a scrutiny of expenditures for supplies and consequent necessity for the adoption of a fairly adequate system of accounting in that department is made necessary for this reason if no other. In addition to this, it has been found on a number of occasions that careful accounting of supplies has checked serious cases of pilfering, waste and loss of material in other directions. For example, take the case of mine rails; where careful checks of the amounts on hand are kept, there is small probability that the mine foreman will fail to recover all his old rails as fast as the track of which it is a part has ceased to be of use. Again, an inadequate supply of rail, which might also result from poor management of the supply department, will frequently cause the men to pull up a short piece of track close to a room mouth, thus breaking the connection for bringing out the balance of the rail from the interior of the room and either discouraging the recovery thereof or making the cost excessively high, if not prohibitory.

The continued existence of the wasteful beehive coke oven, said Secretary of Commerce Redfield recently, ought to be an offense against accepted business standards, just as higher business standards, will some day think it an economic offense to allow black smoke to escape from a chimney for lack of careful firing.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

If our peace with Germany loiters much longer on the road, and if in consequence our contract with the bituminous miners is much longer delayed, then the call for a short day and a short week and for other short measures (including, as is inevitable with all other things short and stubby, the short dollar) will not be necessary for everyone will be working steadily.

The short day and the short week, the short pound, the short pint and the short foot, the short dollar and short sustenance all line up together. They are all part of the same unhappy and woebegone yet well-known family of Shorts. A few years ago we regarded them as dishonest and led them somewhat resistingly to court, but now they are being openly avowed by the best industrial company. If we agree that everyone shall have a short pound or a short pint, well and good. No harm will be done. If everyone has the short day and short week, we shall be giving one another the same short measure; it will be a fair exchange. The day's work will line up gracefully with the short sack of flour and the undersized loaf, and as the mine-worker is given the short day he will, of course, not make a plaintiff sound when the baby sack or the tiny loaf is handed to him. He is a sport. If he "does" other people, it will be because he expects them to "do" him.

BARREL OF ORDERS FILLS FROM BOTTOM UP

The news from eastern Kentucky, West Virginia and Virginia is largely to the effect that coal is beginning to be sold steadily at a higher price than the Government once set. The barrel of orders is beginning to fill up and, of course, it begins to fill up from the bottom. After a while it will commence to trickle up to Illinois, and the short day and short week will be seen to be contrary to public interest and not at all necessary for the mine-worker—not even for the mine-worker in Illinois.

The labor shortage is troubling every section. In West Virginia an operator was heard lamenting the fact that Count Karolyi had been around to visit the men in his vicinity just before the United States entered the war, and that he had sold the Austrian miners a lot of Austrian bonds. Today all the Austrians in those parts, he said, were getting ready to go to Europe to see if the bonds the Count sold them were really good and negotiable.

A GENERAL EXODUS OF ALL BUT NATIVE BORN

Others are complaining that men are returning to the lands of their nativity in the hope of reuniting and supporting the broken families of their parents; still other foreigners see a chance to satisfy their hunger for the estates of the landed aristocracy. Whether the desertion will be considerable remains to be seen. Inquiries seem to point to a general exodus in West Virginia. The interesting outcome of inquiry is, however, an acknowledgment that the exodus is still in the future and has hardly begun yet.

The State Labor Commissioner of West Virginia is of the opinion that less than 500 aliens have left the state. He bases his estimate on an examination of the records of the two United States marshals in the state and upon reports from coal operators' associations and on those of the United Mine Workers. Though there are plenty to say his figures are too low, one is obsessed with the idea that when the whole condition is sized up the loss of men will not be as great as is prognosticated. That was the case when prohibition was made law in West Virginia. Mining went on more steadily than ever, yet we heard all manner of baleful predictions at the time the law came into operation. Perhaps there is no more reason for fear of a man shortage now than there was then.

In southern Illinois it is said that nearly all the foreign population is scheming to leave. It is said that the credit of the banks is impaired owing to the foreigners withdrawing their savings. It is seriously stated that some mines have lost over a third of their force and that the demand for steamship transportation is beyond the capacity of the agents who are canvassing the field, whatever that may mean. As a matter of fact, slow work is making many foreigners and others in Illinois change their working affiliations, and even causing them to seek other employment. The loss to Europe may not be as great as the loss to more active industries and to more active plants in the same industry. In order to keep their foreign-born miners from returning home the Chicago, Wilmington & Franklin Coal Co. at its Orient mine, Orient, Franklin, Ill., has distributed the button herewith portrayed. It is in the colors of our national flag.

"ONE BIG UNION" DOES NOT APPEAL TO MINER

However much the mine-worker is attracted by the prospect of shorter time and bigger wages and more accident compensation, he does not in general favor the One Big Union. If he thinks his wages too small, he wants to get them raised even if other men suffer. With a single Big Union he would not be able to get any such adjustment. Wages would be raised all around and prices everywhere would go up accordingly, and where then would the miner be? If he is satisfied with his wage, he cannot see where the "One Big Union" can help him. He is beginning to see dimly that he is not merely the "Wage Earner"; he is also the "Wage Payer." When he quits buying business stops. The "One Big Union" of employee against employer does not appeal to him, for is he not employer and employee both—a master when he buys the product of other people's labor and a servant when he sells his own labor? If the "One Big Union" were formed he would not know where to align himself, whether as one of the selling proletariat or one of the buying bourgeoisie.

An operator said the other day that he had 35 automobiles at his mine and that the men were in a hurry to quit early to get into them. Some of the mine-workers hardly know whether they rightly belong to the proletariat or the bourgeoisie, and the "One Big Union" seems better fitted to Europe than the United States or Canada.

WOULD HAVE OPERATORS GIVE BOND FOR WAGES

A peculiar strike in a mine of the Wasson Coal Co. of Harrisburg, Ill., arises from the business failure of the Evans Coal Co. of Equality. The Evans concern contested the payment to its men of certain moneys which they claimed. On an appeal the Wasson company went on the Evans company's bond. As the filing of this bond delayed a settlement, 400 mine-workers in the employ of the Wasson Coal Co. at No. 1 mine of that concern went on strike and a tie-up of all the mines of the company is threatened.

Several operators in the coal fields of Illinois are said to have put up bonds for the payment of the wages of their men who have questioned the ability of the corporations to run the mines at such low figures as they are obtaining for their coal. At the Gus Blair mine, which is controlled by the West Virginia Coal Co., of St. Louis, the men have for some time felt that the coal was being sold at too low a figure to insure the continued payment of their wages. President Farrington of the Illinois United Mine Workers made several attempts to induce the com-

pany to put up the bond. He did not want to see the mine-workers lose their pay, as has often happened during the past six or eight years. Corporations would sell considerably below cost, and as a result fail, depriving the mine-workers of the wages that were their due.

Finally, as the West Virginia Coal Co. refused to put up bond, the mine-workers went on strike. This idleness lasted only a few days, the company giving the men the necessary assurances. The company has seven other mines and the men threatened to close these also if the desired action was not taken. There was a great deal of bitterness as it was alleged that certain other operating interests were annoyed by the "unfair" competition of the West Virginia Coal Co. and wanted the mine-workers to put an end to it by demanding either a bond or the charging of a reasonable and profitable price for the coal mined.

Reports received in Des Moines, Iowa, indicate that the mine workers in that region are looking for an increase in wage when the contract is made.

On June 2 reports from Béthune in the Department Pas de Calais were to the effect that a strike was to be called on that day. It was expected that the mines of the Anzin coal field would soon join in the suspension.

Agitators Work on the Unenlisted Foreigners

The Western Coal Operators' Association of Canada presented a memorandum to the Industrial Relations Commission (which is taking evidence throughout the Dominion of Canada with regard to the relations between employer and employee) advocating the appointment of an independent board to take control of the coal industry in western Canada. "Such a board," the memorandum states, "should, in our opinion, be made up of one man thoroughly familiar with the problems of the operators; one man familiar with the problems of the workmen; and a third with such qualifications and experience as would commend him to all as a reliable chairman. The industry has reached a point where, although permission is granted to sell coal at a given figure, it is impossible to do so on account of competition from other fields, chiefly American."

Discussion and consideration of the position of the coal industry occupied practically the whole time of the Commission on the afternoon of Saturday, May 3, and the operators appeared to be one in the opinion that joint councils of the employers and employed could not bring harmony to the industry at the present time because most of the miners—85 per cent. of them according to a Drumheller operator—were foreigners whose ignorance made them a prey to agitators. It might be different were the proportion of English-speaking miners large, but that was not so and was not to be looked for, as most of such men had enlisted and many of those returning were not fit to go back to their former work. The Board of Control which the operators recommended, it was thought, should have the same power as was given W. H. Armstrong, the war-time director of coal operations in District 18, as established by the U. M. W. of A. (Eastern British Columbia and the Province of Alberta).

W. F. McNeill, secretary of the operators' association; John Shanks, manager of the Brazeau collieries; Jesse Gouge, operator; and W. S. Henderson, operator of Drumheller, represented the organization indicated.

Mr. McNeill stated that two mines were on strike against the order issued by the director of coal operations, but he admitted that the strikes were unauthorized by the union officials. Discussing housing conditions, witness said there were no complaints from the permanent camps, but only from new camps where bunk houses had to be used.

The markets of the British Columbia mines were in Montana and Washington, and those of the Alberta mines were in Alberta, Manitoba and Saskatchewan. Freight rates hampered the operators in competing in Manitoba with Pennsylvania anthracite.

John Shanks, manager of the Brazeau collieries, described in detail the arrangements made between his company and its employees. The collieries are situated 120 miles west of Red Deer and six miles from the nearest village. The government leases land to the miners through the company, which has erected four-room houses at a cost of about $900 and rented them to the employees at $10 a month. Five-room houses are rented at $15 a month. A subsidiary company runs a store in the mining village. The desire for better working conditions is one of the primary causes of that discontent which has become acute since the war began in 1914. "Blanket men," who brought their own blankets and slept in bunkhouses, are no longer content with such meager conditions. A hospital charge of $2 a month is made to each man, and for this a doctor has been engaged. He pays a nurse and the staff of the institution.

Men in the mines, said the witness, are not disposed to neglect their work or be dilatory on the job, but it is fair to say that they have become very independent. The "labor turnover" is large, because many young men are employed, and when they have earned a considerable sum they go away to the cities and towns.

Two operators from Drumheller gave evidence, John Henry Gouge and W. S. Henderson. Mr. Gouge declared that the cost of getting out coal was $2.53 for labor alone, exclusive of the cost of management and overhead charges. He did not think that any operator would be opposed to joint councils, but they would be unworkable because the employees, mostly foreigners, would not coöperate with them.

Mr. Henderson said that he employs when working 150 men, but that he had practically shut down his mine since Apr. 1. The price of coal was high, he said, because wages had been boosted to such a level as was unfair to the operator, to the general public and to the miners themselves. He testified that "If coal can be marketed at $1 a ton less, we can compete in Manitoba with the hard coal" [from the United States].

Mr. Anderson stated that there were 22 mines in the Drumheller district, each of which had its own small system of lighting and its own water supply. This duplication of effort is expensive business, and Mr. Henderson suggested that the government should take over the mines, install a central lighting and central water system, and thus cheapen the cost of running the mines. Enough slack coal, not worth shipping, was wasted in the vicinity of the mines to supply fuel for a power station for the operation of all of them. Attempts to run the mines amicably had been made, but "foreign-born agitators had upset the whole thing by Bolsheviki talk."

E. Mart, general manager of the Canadian Coal Co. collieries, the first witness at the meeting on Monday (May 5) said that calculations showed that the advance in wages in mining had more than compensated for the increased cost of living. He spoke feelingly about agitators who felt no responsibility like an ordinary British subject, yet earned from $10 to $20 a day. These agitators, he declared, were the chief causes of the undue discontent.

Illinois no Longer Pays Union Dues

The severe industrial depression, which has decreased the running hours of the Illinois coal mines to less than half of full time and has closed down many of the mines altogether, is given as the reason for the abandonment of dues and assessments by the United Mine Workers in the Illinois District. Frank Farrington, president of that district, announced recently that the 85,000 members of that state would be relieved of the obligation to pay dues for at least three months and perhaps longer.

May Not Use Boys on West Virginia Tips

Under a ruling of the Commissioner of Internal Revenue received by the State Labor Commissioner of West Virginia, no boys can be employed in or around coal mines. The State Labor Commissioner had put the question to the Revenue Commissioner as to the employment of boys on tipples. The commission replied that such employment was forbidden and that any company which employed boys in violation of the ruling would be called upon to pay as a penalty an amount equal to ten per cent. of the annual net income of the company.

DISCUSSION BY READERS

EDITED BY JAMES T. BEARD

Certification and Safety

Letter No. 6—I can endorse much that has been said by by J. M. Roddie, in his letter, *Coal Age*, Apr. 17, p. 723, regarding the examination of candidates for positions of responsibility, in coal mines. If my memory serves me right, the Coal Mines Regulation Act of Great Britain requires that the examining board shall be composed of three operators, three local men appointed by the Government, and, further, that the applicant must have five years' practical experience in mines or have been under the supervision of a mining engineer for three years'.

It was in England that I obtained my first certificate to act as mine manager. It was the practice then that a young man of 20 years of age, of wealthy parents, could be apprenticed to a mining engineer or general manager for a period of three years and would then be eligible to take charge of mining operations.

The young man would be taken into the mine every day by the mine boss or overman, who would generally be pestered to death with his stupid questions, and this would continue for the three years of the young fellow's apprenticeship. During the same time, the lad would attend mining classes every Saturday. At the examination, which was regularly held once a year, such a candidate was seldom refused a certificate, after which he was generally pushed into a good job.

THE PRACTICAL MINER AND THE STUDENT BOSS

On the other hand, the practical, experienced miner, who managed by hard study to pass the examination and get his certificate was rarely ever given a position higher than under-manager or foreman and made responsible for getting out the coal. The student boss would come into the mine for a short time each morning, find some fault and go on top again. Such were the conditions regarding certification in England at that time.

In this State (Indiana) the examining board is composed of chief and deputy mine inspectors, appointed by the governor. From what we read of appointments under politics, in this and other states, leads one to fear that many members of examining boards have not had the practical experience in coal mining that would qualify them to pass the examination given by their own board.

This statement, of course, does not apply to all examining boards; but it teaches the lesson that politics should have no bearing or influence in matters pertaining to the safe management and inspection of our mines. Coal mining is a dangerous occupation at the best. It is a business that should be supervised by careful and experienced men who are fully qualified for that work.

Speaking of the influence of politics in mining appointments, a friend of mine, whom I know was fully qualified to sit on any board, applied for the position of examiner. A little later, however, the vacancy was filled by the appointment of another who, though less qualified, had a stronger political pull.

In his letter, Mr. Roddie suggests that a mine foreman candidate should have an experience of nine years in practical mine work. Let me say that, while some men would learn a lot of mining in that time, others would require three times nine years to qualify them for the position of mine foreman. Mr. Roddie regards it as a mystery that mine inspectors do not take more part in discussion; but my observation is that it is the fear of the loss of their position that deters them from giving expression to their views.

Linton, Ind. MINE FOREMAN.

[1]At present, the Coal Mines Regulation Act of Great Britain (1911) provides that the Secretary of State shall form an examining board for mining examinations, which shall be constituted as follows: Six representatives of owners or agents of mines, or managers of mines, or mining engineers; six representatives of workmen employed in mines; the chief inspector and two divisional inspectors of mines; two persons eminent in mining and scientific knowledge. The act further provides that the candidate must be at least 23 years of age and have had practical experience, in mining, of not less than five years, a portion of which must be in mines of the United Kingdom. But an applicant holding a diploma or having an approved degree, is required to have but three years of practical mining experience.

The Burrell Gas Detector

Letter No. 1—Some two or three years ago, I remember there was a full description given in *Coal Age* of a new instrument that was devised by George A. Burrell for the detection of gas in mines (Vol. 9, p. 157). In that article, I believe the claim was made that the instrument was ten times as sensitive as an ordinary safety lamp.

Since that time, I have had excellent opportunities for making a large number of practical tests with this instrument in the mine and, at the same time, taking samples of the air tested and submitting them to careful chemical analysis. The results show a remarkable accuracy in the practical tests made in the mine with the instrument, and I take pleasure in submitting the following table of the tests made, 149 in all, which I trust will prove of interest to the readers of *Coal Age*.

Many of these tests were made by myself personally, and I have no hesitancy in saying that the detector gives good results when carefully handled. Particularly, in making a test where the percentage of gas is so small as to be liable to escape detection with the most sensitive safety lamp in use, the results obtained with the Burrell detector are extremely gratifying.

IMPROVEMENT MADE IN THE ORIGINAL CONSTRUCTION INCREASES ACCURACY OF TEST

It should be known that the original construction of the detector has been slightly altered, recently. A letter received a short time ago, from J. T. Ryan, vice president and general manager of the Mine Safety Appliances Co., Pittsburgh, Penn., the sole manufacturers of this instrument, states that the alterations were made for the purpose of taking better care of the changes in temperature that result from the ignition of the methane when that gas is present within the instrument. Mr. Ryan says, "The essential difference in the con-

struction of the new type detector is that, instead of having a single brass tube, it now has two concentric tubes, the outer one having about a half-inch larger diameter, and the space between the tubes being filled wih Keiselgor, an insulating material."

Following are the results of the practical and chemical tests to which I have previously referred:

COMPARATIVE TESTS TAKEN WITH BURRELL GAS DETECTOR AND CHEMICAL ANALYSIS IN THE CROW'S NEST DISTRICT

Sample No.	Chemical Analysis	Burrell Detector	Sample No.	Chemical Analysis	Burrell Detector
158	0.45	0.4	304	1.54	1.0

Average of 35 samples—1.02 0.98

Totals average of 149 check samples taken during 1918—Chemical analysis 1.17%; Burrell gas detector, 1.10%.

The Burrell gas detector is now being used by all the mine inspectors in this province, and is also provided by the coal companies operating in the province, for their officials to search for percentages of gas lower than can be detected with the ordinary safety lamp.

GEORGE WILKINSON,
Chief Inspector of Mines.

Victoria, B. C., Canada.

Efficiency of Mine Workers

Letter No. 1—Much has been said in the columns of *Coal Age* about the efficiency of mine officials, foremen and firebosses; but long and close observation has convinced me that not enough attention is being paid to the efficiency of the "prime producer," who, I would say, was the miner or the general worker employed in the mine.

The average coal-mining man will agree with me that no matter how efficient a foreman may be, he cannot get results unless he has some efficient workers at the coal face. The foreman may be an excellent manager and able to direct the work, but that will not take the place of the work that must be performed by the men who break down and load the coal.

It is quite true that the output of a mine depends on many different things and, perhaps, the most important of these is a good foreman. This is true, today, more than ever before, because of the increasing exhaustion of the high coal and the extended development of our mines, together with the varied equipment now employed in large up-to-date mines. It is clear that it will require greater efficiency in the miner to produce his shift of coal when working a 2½ or 3-ft. seam than where the coal runs from 8 to 12 ft. in thickness.

Need of Training Miners To Be Efficient Workers

It is these conditions that lead me to believe that more attention must be paid to the efficiency of mine workers, particularly the miners. They must be trained, by every possible means, to become better workers, for their own good and that of the industry. There will then result a noticeable increase in the production of coal and a proportionate decrease in the number of mine accidents. In the past, coal-mining companies have confined their efforts, in securing greater efficiency, too much to the colliery officials and neglected the importance of training the workers and developing in them an equal efficiency.

In respect to wages, it is true that in every mine there are those who make high wages and others who make very low wages. For some time past I have been studying the payroll of contract miners and find that, while some miners have produced from 60 to 70 cars of coal in two weeks, others working in the same seam and under the same conditions produced but one-half or two-thirds of that amount. This fact reveals a low standard of efficiency and argues for the need of training our miners.

The question will be asked, How is this to be done? Looking at the situation and comparing the daily production of six, eight and ten cars of coal by some miners, with the four, five and six cars produced by others, under the same conditions; and, considering the complaints made by these latter men that the coal was "hard to cut," "worked poorly," or some similar excuse, one is convinced that there is something radically wrong with the men themselves. Either they have not the same knowledge of the structure of the coal, or they fail to use their judgment, or they are less industrious than their fellows who are better producers and more efficient workers.

This comparison of results suggests the remedy to apply to secure greater uniformity in the work of the miners, by striving to make then all equally efficient with the best workers. It would seem that a good plan

to adopt would be to single out the best workers and make each of these instruct about a dozen of the poorer class. The results should appear in the increased production effected in a month. To my mind, this matter is of sufficient importance to warrant the making of a reasonable trial.

Another feature that should be considered, in this connection, is the waste of mine supplies, on the part of inefficient workers. More timber, tracking and other material will be required by the inefficient worker, for the same production of coal. Take, for instance, two company miners employed on dead work, the one being efficient and the other wasteful. It will often be surprising to note the difference in the cost of powder, dynamite, spikes, tracking, and tools furnished these men on the company account. Here, again, the need of training the less efficient worker in the proper methods to employ is plainly evident.

Inefficiency of Workers Causes Accidents

Lastly, the frequency of mine accidents, owing to the inefficiency of workers, is a factor demanding the same careful consideration. Practically all coal companies are doing everything in their power to reduce the number of accidents in their mines, but few realize that the lack of training inefficient workers is a most prolific cause of accidents and loss resulting therefrom. Close observation shows that the majority of mine accidents result from the violation of some rule or regulation, by a careless, indifferent or ignorant worker.

While it is true that accidents will happen, it is equally true that many mine accidents can be avoided, by the careful training of all mine workers and by greater discipline in the mine. One of the best means of educating and training men, in respect to what is required to insure their own safety and that of their fellow workers, is to get the men together for the purpose of discussing questions relating to their work and the dangers to be encountered.

Many of the larger companies hold such meetings monthly or semimonthly and it goes without saying that the good accomplished thereby has been far reaching and effectual in reducing the number of accidents in the mines of those companies. To vary the monotony and make the meeting more attractive, the regular business is preceded by a little entertainment, by local talent. This always puts the men in good humor and opens the way for a more animated and general discussion of the topics that are presented later.

Joseph R. Thomas, Asst. Foreman,
Plymouth, Penn. Colliery No. 3, Hudson Coal Co.

Letter No. 2—It was pleasing to read the foreword in the issue of *Coal Age*, Apr. 24, entitled "Meeting the Situation." It is just such temperate discussion of the trials that miners are going through, at the present time, that will aid largely in the solution of labor troubles following the war.

As a miner, or rather a mine examiner, I could not help but feel that I would like to have voiced a protest, at the reference made to the suggestion of a 6-hr. day for coal miners, which appeared in *Coal Age*, Apr. 3, p. 629. After all that has been said in regard to the efficiency of mine officials, I feel that it would only be justice to the common miner to consider the question of developing greater efficiency in the work that he performs as his share in the industry.

When I think of the many wrongs imposed on the miner, in the operation of our coal mines, it makes me think that the claim of the Kaiser that "Might makes right," is prevailing to a great extent in the management of our large coal corporations. It does not require a volume of statistics to reveal the great waste of energy in the production of coal, to say nothing of the sacrifice of thousands of lives of mine workers.

Long Hours in the Mine Increases Accidents

Many of us whose lives are spent, day after day, in the dark recesses of the mine, realize the destruction of manpower through the senseless system enforced by the coal companies, in keeping their men underground longer than is required to meet the demand for coal. No man can be an efficient worker and continue as such under these conditions. Also, there is no question but that there is greater liability to accident caused by prolonging the hours of mine labor beyond what is required for the performance of the necessary work to meet the demand for coal.

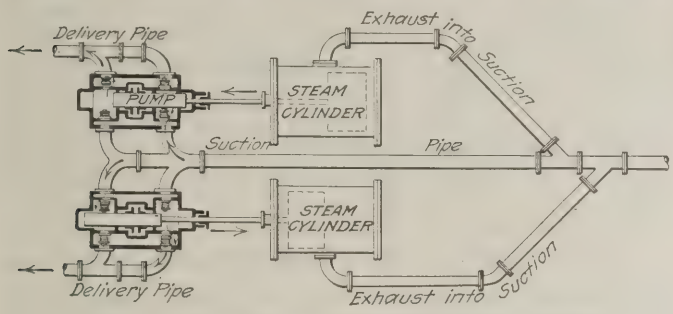
Formerly, it was the agreement between miners and operators that eight hours should constitute a working day, and the miner was required to be at work at the coal face that length of time. In many instances, the miner must travel long distances, a mile or more, to reach his place, after entering the mine. This means both an increase of labor and loss of time to the miner, keeping him from home and underground ten or even twelve hours of the day.

Shorter Hours Mean Greater Efficiency

The miners' viewpoint is that greater efficiency would result from a shorter working day. The suggestion is not prompted by selfish motives; it is logical and reasonable when one considers present conditions and has in mind the attainment of the highest efficiency in the worker. Today, there is a certain amount of coal needed in the country and for export. It is estimated that this coal can be produced in half the present contract time.

Someone will suggest that this is an outgrowth of Bolshevism, but it is not; it is only common sense. Speaking of the spread of Bolshevism to this country, coal operators are alone to blame for the large proportion of this low-class of the foreign element now employed in our mines. When the fortunes of war were imperilled, it was the firm, loyal attitude of our American miners that withstood the attempt of this foreign element to tie up the coal industry of the country. It was rare to find an American miner, who was in sympathy with the strike movement demanded by that element, whose cry was "Throw down your tools and end the war," to which our miners replied, "Pick up your tools and win the war."

Having won the war through their fidelity and loyalty, the American miner wants an American living. He is convinced that the present order of things is wrong, and the conditions prevailing at the mines today support him in his conclusion. Since the armistice was signed, there has been no work worth mentioning at the mines, or that would afford an industrious miner the living he is able to earn. Notwithstanding this, our miners have been patient, thanks to the true-blues among them, and the determination grows that in the future "Americanism" must be the watchword if we are to develop the highest efficiency in mine workers.



Staunton, Ill. W. M. Chambers.

Exhaust from Steam Pump

Letter No. 7—In connection with the proper disposal of the exhaust steam from a mine pump, I am submitting herewith a sketch or diagram of the plan of a duplex, double-acting, plunger pump, having the exhaust port of each steam cylinder connected with the suction line of the pump.

The length of the suction line was only 18 ft. and the pipe was most of the time submerged in the water of the sump, which greatly reduced the head under which the pump operated. Only when the water in the sump was low was there any trouble. At such times, the pump would knock a little, which was a warning that it was time to shut off the steam and stop pumping.

The arrangement shown in the sketch gave good results. I agree fully with the editor in the point he

PLAN OF DOUBLE-ACTING, DUPLEX PUMP

makes that, should the exhaust connection enter the suction pipe at the top of a long suction lift, there would probably result a back pressure and possibly water-hammer, owing to the steam not being quickly condensed by immediate contact with the water as it enters the pipe.

In another arrangement, adopted at another mine, I conducted the exhaust steam from the pump into a tank that was always kept full of cold water. This was supplied from the rising main or column pipe, a 1-in. pipe being used to conduct the water from the main to the tank. The flow of water into the tank was regulated by opening or closing a valve in this connection.

In a short suction lift where the suction pipe is kept full of water during the operation of the pump, the exhaust should be conducted into the suction pipe as close to the pump as convenient, unless the plan is adopted of using a cold water tank such as I have just mentioned. In my opinion, the exhaust from a mine pump should never be connected with the column pipe, as that would have a tendency to interfere with the uniform discharge of the pump to the surface and oppose its regular action and would probably cause a water-hammer that would not only be harmful but very annoying.

WM. DICKINSON, SR.

Oak Hill, W. Va.

Letter No. 8—In connection with the discussion of the question of disposing of the exhaust steam from a pump in a mine, allow me to cite an instance where this was done to great advantage, in a mine of which I had charge.

The pump, in that case, was located at the foot of a 32-ft. shaft and drew its water from a sump 600 ft. back in the mine, although the total suction head was only 12 ft. Previous to the time of which I speak, the pump had exhausted its steam into the air shaft. However, the development of the mine now required the installation of a ventilating fan at the top of the shaft; and, because the men were unable to work over the shaft when the pump was in operation, it became necessary to make some arrangements for disposing of the exhaust steam.

To do this, I resorted to the scheme of turning the exhaust into the suction pipe of the pump. For that purpose, we tapped the suction line at a distance of 70 ft. from the pump, making the connection between that point and the pump by means of a pipe of the same size as the exhaust port of the steam cylinder. A tee was inserted in this pipe near the pump and provided with two globe valves, one on each side. By closing one of the valves, the other being open, it was possible to exhaust either into the atmosphere or through the pipe into the suction line, as desired.

The scheme worked well. When starting the pump and until it had caught the water and filled the suction pipe, the two globe valves just mentioned were arranged so that the exhaust steam was discharged into the atmosphere. But, as soon as the suction pipe was full of water and the pump was operating properly, these valves were changed. One was opened and the other closed as nearly as possible at the same time, so as to avoid drawing any air into the suction line. The pump now exhausted into the suction and the result was that its speed increased from eight to ten strokes a minute, which was a considerable gain in the quantity of water discharged, per pound of steam used to operate the pump.

Not only did this arrangement get rid of the annoyance of the exhaust steam in the shaft but the pump worked quietly, and there was no water-hammer such as had proved a great annoyance in its previous operation. Turning the exhaust steam into the suction pipe produced a cushioning effect on the piston before the steam was wholly condensed. Also, the partial vacuum produced in the suction lift, owing to the condensation of the steam in that pipe, effected a considerable saving in the power required for pumping.

Referring to the suggestion of exhausting the steam into the column pipe into which the pump discharges its water, let me say that such an arrangement would be very unsatisfactory, and I question whether it would work at all. There would certainly result a back pressure when the pump was compelled to work against its own exhaust, to say nothing of the back pressure due to the water column, which would be very much greater and would seriously interfere with the working of the pump. Let me advise that this should never be done.

Meadowland, Penn. D. F. M.

Letter No. 9—The question of exhausting steam into the suction pipe of a mine pump, as discussed in *Coal Age*, has led me to make some interesting figures for the purpose of ascertaining how much the steam exhausted, in any given case, would raise the temperature of the water pumped. My figures appear to show that the rise in the temperature of the water would not ordinarily be sufficient to interfere seriously with the pumping.

Assume, for example, that a pump is lifting water from a sump 12 ft. in depth and is located, say 2 ft. above the surface of the water, making the total suction lift 14 ft. Suppose, further, that this pump is discharging under a total head of 70 ft., including friction.

A head of 70 ft. corresponds to a water-end pressure of 70 x 0.434 = say 30 lb. per sq.in. and, assuming an available steam pressure of 120 lb. gage, at the throttle of the pump, the ratio of the area of the steam end to that of the water end of the pump is 120:30 = 4:1. This means that for every cubic foot of water pumped, there will be required 4 cu.ft. of steam.

Calculating the Rise in Temperature Due to Heat in the Exhaust Steam

At sea level, a gage pressure of 120 lb. corresponds to an absolute pressure of 135 lb., practically. At this pressure, a pound of steam contains 1191.5 B.t.u. and has a volume of 3.35 cu.ft. Therefore, for every cubic foot of water raised, there will be required, in this case, 4 cu.ft.; or, 4 ÷ 3.35 = 1.194 lb. of steam. The heat in this steam is 1.194 × 1191.5 = 1422.6 B.t.u. and this is, therefore, the heat required to be absorbed by each cubic foot of the water pumped. Now, taking the weight of a cubic foot of water as 62.4 lb., the heat required to be absorbed, per pound of water pumped, is 1422.6 ÷ 62.4 = 22.8 B.t.u. This calculation shows that the temperature of the water will be raised 22.8, or say 23 deg. F., since 1 B.t.u. is the quantity of heat required to raise the temperature of 1 lb. of water 1 degree of the Fahrenheit scale.

Therefore, assuming the original temperatrue of the water in the sump is, say 60 deg., its final temperature in the pump and the column pipe would not much exceed 83 deg. under the assumed conditions. It appears to me that these figures are suggestive of the advantage to be gained by condensing the exhaust steam in the suction pipe of a pump.

To carry the calculation a step further, we may ascertain the temperature at which vapor would form under the pressure due to the suction head. In this case, we find an absolute pressure of 14.7 — (14 × 0.434) = 8.6 lb. per sq.in. Reference to steam tables shows that steam or water vapor, at this absolute pressure, has a temperature of 186 deg. F. Therefore, condensation of the exhaust steam will continue in the suction pipe, in the case assumed, where the temperature cannot exceed 83 deg. F.

Frederick L. Serviss, Sr.

Golden, Colo.

Living Conditions at Mines

Letter No. 5—No one who has lived much of his time in mining camps can fail to read with interest the letters that have been written thus far emphasizing the need of good living conditions in mining towns and particularly in camps, which are often neglected.

The coal-mining industry is in a class by itself, in respect to the living conditions surrounding its workers. Unlike a factory, a coal mine must of necessity be located where the coal is to be found. This is often in an isolated place far from any railroad other than a branch track laid to the mine.

Isolation of Mine an Important Consideration

The isolation of the mine makes it all the more important that the operator or company should provide, not only means of transportation to and from near-by towns or villages, which would enable their employees to go and come as occasion may require, but the company should build good houses for its men and start a little town of its own at or near the mine.

In most of these isolated camps, there is no means of reaching the outside world, except to go and come on a coal train that has no regular schedule, but is liable to run at any time. Frequently, an old stage is used to convey passengers back and forth over roads deep in mud, which makes traveling slow and tedious.

It is clear that such conditions as these, at a coal mine, makes it difficult to hold men, except the poorest class of workers. No miner who has a family or has children to educate would consider for a moment living in such a place, especially if there are no schools, churches and other privileges at hand. I recall an instance that occurred some years ago when I was working at a mine in West Virginia where the conditions were much as I have just described, the mine being located at a considerable distance from any town or village.

It happened that, owing to slack work at the mines in the Middle West, a number of miners came to West Virginia from that locality and applied for work at our mine. The men were good coal miners, but they stayed only a short time and left to seek work elsewhere. In answer to my inquiry as to why they wanted to leave, one of them said that he had had to lose a whole day each week in order to get a shave.

Poor Conditions Keep Good Workers Away

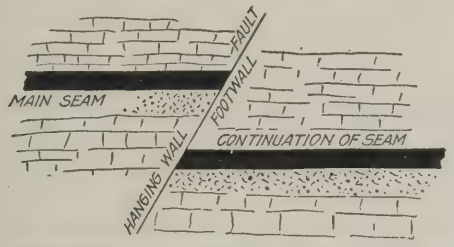
It can well be imagined that a small place where there was no barber would not afford many other conveniences of life, and it will cause no surprise to learn that such was the case in this place. A coal train was the only means of transportation to the nearest town. It carried an old caboose and had no regular schedule for running. On the whole, there was nothing about the place to invite good workers or to hold the men already employed there.

At another mine, in the same state, conditions underground were ideal; but living conditions, on the surface, were poor indeed. It was not uncommon for 25 or 50 men to leave the place every payday and not return for a week or ten days. The mine was equipped with the most up-to-date machinery and appliances, but the company had yet to learn that good conditions in the mine are not all that is required to get a good class of workers and to hold them. As a result, breakdowns were frequent and the cost for machine repairs was high, because the men did not know how to run and care for the machines in their charge.

It is a mistake to think that higher wages will hold men in a camp where the living conditions are poor and there are no amusements and other privileges. We have much yet to learn in this direction when we fail to realize that the improvement of living conditions, at mines, is a profitable investment.

In the excellent foreword that appeared in *Coal Age*, Apr. 24, entitled "Meeting the Situation," it is stated "if the war has taught nothing more than that money is not the universal cure for all labor troubles, it has done some real good." The foreword emphasizes the fact that what the laboring man most desires is to give his own home folks a recognized position in society and make life worth living. The boys coming home from the war will seek work where they can enjoy the highest privileges and any company that does not realize this fact will experience a scarcity of labor, for there will be no oversupply of mine workers for some time to come.

Cleaton, Ky. Ostel Bullock.



INQUIRIES OF GENERAL INTEREST

ANSWERED BY JAMES T. BEARD

"Hanging Wall" in Mining

Please explain the meaning of "hanging wall?"
Shamokin, Penn. STUDENT.

The expression "hanging wall," as used in mining, refers to the upper portion, geologically, of a slip or fault of dislocation. Where the strata are regular, or have not been folded, the hanging wall is above the

SHOWING A FAULT OF DISLOCATION

fault line, as shown in the accompanying figure; but if the strata have been folded, as occurs at times even in the coal formations, the hanging wall may be below the fault line. The opposite wall is the "footwall."

Meaning and Determination of "Candlepower" in Lighting

When estimating the intensity of light, in comparing the illuminating power of different sources of light, the value is always given in "candlepower." It is a common expression and, yet, I believe few understand its real meaning or, in other words, know what determines the candlepower of a lamp, in actual practice. In searching for the meaning of this expression, I have been unable to find a satisfactory explanation.

Also, kindly explain the means and method employed for determining the candlepower of any source of light, such as a mine lamp, an electric bulb or other means of lighting. CURIOUS.

Salt Lake City, Utah.

A full explanation of the term "candlepower," as expressing the intensity of any light, is given in the treatment of the "Photometry of Safety Lamps," p. 290, *Mine Gases and Explosions*. In the pages following (291, 292) will also be found the method employed to determine the candlepower of any source of light.

A candlepower is a unit of measure adopted arbitrarily to express the value of the illuminating power of different lamps when burning different illuminants. This unit of measure is the intensity of light produced by the burning of a well-trimmed sperm candle (6's), weighing six candles to the pound. The so-called "standard candle" is of such proportion that its flame will consume exactly 120 grains of spermaceti in an hour, when burning in a quiet atmosphere of pure air.

As is well known, candles are made of different materials, such as paraffin, stearin, tallow, wax and spermaceti. The last-named material, having the greatest illuminating power except extra-refined paraffin, has been chosen as the standard of candlepower.

Taking the illuminating power of a standard sperm candle as unity or 1, the candlepower of different materials is as follows: Paraffin, 0.76; stearin, 0.77; tallow, 0.83; wax, 0.92; spermaceti, 1.00; extra-refined paraffin, 1.14. The degree of refinement of the paraffin, however, being somewhat uncertain, spermaceti has been taken as the standard of candlepower. The quality of pure spermaceti being constant, the standard sperm candle burns with a uniform intensity of light and furnishes a good standard of measurement for determining the illuminating power of different sources of light.

In ascertaining the candlepower of any given source of light, as for example, a common Davy safety lamp, burning sperm, lard or cottonseed oil, it must be remembered that the intensity of light from any source varies inversely as the square of the distance at which it is measured. For example, taking the light of a standard sperm candle, measured at a unit distance (1 in. or 1 ft.) from the candle, as unity or 1, its intensity at a distance of two units is $(\frac{1}{2})^2 = \frac{1}{4}$. The same is true in regard to the intensity of any source of light to be tested.

Now, in order to apply this principle in the comparison of the illuminating power of a Davy lamp with that of a standard sperm candle, these two sources of light are placed on opposite sides of a screen. The screen consists of a sheet of white paper, having a spot the size of a half-dollar at the center, made translucent, with a little grease or melted wax. When this screen is lighted equally on both sides, the translucent spot at the center disappears.

Utilizing this fact, the sources of light, the sperm candle and the lamp to be tested, are arranged on opposite sides of the screen. Suppose, for example, the distance of the standard candle from the screen is ten inches, the inch being taken as the unit of measurement, the intensity of light thrown on the screen by the candle being inversely proportional to the square of the distance is $\left(\frac{1}{10}\right)^2$, or $\frac{1}{100}$, the candlepower of the candle being 1.

In like manner, according to the same principle, the candlepower of the lamp tested, assuming that at a distance of 4 in. it gives equal illumination of the screen with the candle, is $\left(\frac{x}{4}\right)^2$, or $\frac{x}{16}$.

Then, since the illumination of the screen by the lamp at a distance of 4 in., is equal to that due to the standard candle at a distance of 10 in., we have

$$\frac{x}{16} = \frac{1}{100}; \quad \text{and} \quad x = \frac{16}{100} = 0.16 \textit{ candlepower}$$

Therefore, the candlepower of a Davy lamp burning sperm oil, as determined in this manner, is 0.16 candlepower. In other words, the light given out by one hundred of such lamps would be equal to that given out by sixteen standard sperm candles.

EXAMINATION QUESTIONS

EDITED BY JAMES T. BEARD

British Columbia Examination First Class, Nov. 20, 1918

(Selected Questions)

Ques.—In an air-course 6 x 8 ft. in section and 5500 ft. long, what is the velocity of the air current when the water gage stands at 2 inches?

Ans.—A water gage of 2 in. corresponds to a pressure of 2 x 5.2 = 10.4 lb. per sq.ft. The sectional area of the airway being 6 x 8 = 48 sq.ft., and its perimeter, 2(6 + 8) = 28 ft., the velocity of the air circulated in this airway by the given pressure is

$$v = \sqrt{\frac{p\,a}{k\,l\,o}} = \sqrt{\frac{10.4 \times 48}{0.00000002 \times 5500 \times 28}} = 402.6\,ft.\ per\ min.$$

Ques.—(a) Explain the principle of the ventilating fan. (b) What conditions in the mine would govern you in determining the diameter and width of the fan?

Ans.—(a) The action of all centrifugal ventilators depends on the centrifugal force developed by the revolution of the air contained within the fan blades. The weight of the revolved air develops a force acting radially outward from the center of the fan, which forces the air from the center toward the circumference, where it is discharged into the annular space surrounding the fan blades and passes into the fan chimney, if the fan is exhausting the air from the mine; or is conducted into the fan drift and thence into the mine when the fan is forcing the air or acting as a blower.

(b) Every mine has a certain resisting power, depending on the length and size of its airways and number of splits and which is expressed by the ratio of its area of passage to the rubbing surface. This ratio is properly the potential factor of the mine, as it determines the possible circulation in that mine, produced by a given pressure or power.

The calculation of the proper dimensions of a fan required to circulate a given quantity of air against a given mine potential is a problem for the engineer. Briefly, it may be said that the diameter of the fan or the diameter of the circle described by the blade tips is a factor of the unit pressure required to circulate the given quantity of air against a given mine potential. Roughly speaking, a certain peripheral speed or velocity of the blade tips is required to produce this given pressure, which enables a fairly close estimation of the diameter of the fan.

On the other hand, the width of the fan is largely a factor of the quantity of air required to be circulated. For example, in average mining practice, the width of a centrifugal fan, having radial blades with lips curved forward in the direction of motion to lessen the shock of the entering air, may be taken as 1/64 of the square root of the quantity of air required. Thus, the width of a fan designed to circulate 150,000 cu.ft. of air per min., in ordinary mining practice, is approximately $1/64\sqrt{150{,}000}$ = say 6 feet.

Ques.—(a) If, in an airway 72 sq.ft. in sectional area, the velocity is 550 ft. per min., what will be the velocity if the area is decreased to 60 sq.ft.? (b) What is the horsepower in each case, if the water gage is 1.9 inch?

Ans.—(a) This question is indefinite, being incomplete. For the same quantity of air in circulation, the velocity would vary inversely as the area. The area being reduced in the ratio 60/72, or $\frac{5}{6}$, the velocity would be increased in the ratio 6/5; and would then be 6/5 (550) = 660 ft. per min. However, this would not conform with the condition of a constant water gage (1.9 inch).

It is reasonable to suppose that the reduction of area took place through the settlement of the roof. It may be assumed that the original airway was 6 x 12 ft.; sectional area, 72 sq.ft. The settlement of the roof reduced the height of the entry to 5 ft., giving a sectional area of 5 × 12 = 60 sq.ft. Now, for a constant water gage, the length of the airway remaining unchanged, the velocity varies directly as the square root of the area and inversely as the square root of the perimeter; or directly as the potential factor, $\sqrt{a/o}$. Finding the potential factor in each case, we have

Airway 6 × 12, $\sqrt{a/o} = \sqrt{72/36} = \sqrt{2} = 1.414$

Airway 5 × 12, $= \sqrt{60/34} = \sqrt{1.7647} = 1.328$

But, since the velocity varies directly as the potential factor, the velocity ratio is equal to the potential ratio, and calling the required velocity x, we have

$$\frac{x}{550} = \frac{1.328}{1.414} = 0.939$$

$$x = 0.939 \text{ x } 550 = 516.5\ ft.\ per\ min.$$

which shows that the velocity is decreased when the sectional area is decreased in the airway, the pressure being maintained constant.

(b) The quantitiy of air passing in the original airway is 72 x 550 = 39,600 cu. ft. per min. The water gage being 1.9 in., the horsepower producing circulation is

$$H = \frac{Q\,p}{33{,}000} = \frac{39{,}600 \times 5.2 \times 1.9}{33{,}000} = 11.86\ hp.$$

Again, the quantity of air passing under the same gage when the sectional area has been reduced to 60 sq.ft., is 60 × 516.5 = 30,990 cu.ft. per min. The horsepower required for this circulation is, therefore,

$$H = \frac{30{,}990 \times 9.88}{33{,}000} = 9.28\ hp.$$

Ques.—What system of haulage would you install in a dry and dusty mine? Give reasons fully.

Ans.—If the mine plant is equipped to furnish compressed air for haulage motors, no better system can be adopted, in a dry and dusty mine, than a compressed-air system, because the air exhausted by the motors will assist the ventilation. If compressed air is not available some form of rope haulage should be employed. Electric haulage should never be considered in such a mine, because of the danger of ignition of dust by sparking of wires, especially if a little gas is present.

COAL AND COKE NEWS

Harrisburg, Penn.

A bill is scheduled to pass the state Senate and be sent to Governor William C. Sproul for signature. It is claimed that this bill will drive 10 of the largest insurance companies of the country from the field of Pennsylvania as regards workmen's compensation and result in monopolistic state insurance, notwithstanding the fact that these companies combined to take care of workmen's compensation in the coal fields. Because of its technical nature, the bill went through the House without opposition, few, if any of the members understanding it. Little opposition to it is expected in the Senate.

The bill was introduced by Representative Hess and carries amendments to the act of June 2, 1915, which create a rating bureau to be approved by the insurance commissioner and absolutely under his control, this bureau to fix all rates for compensation insurance. The bill is said to have been drawn and presented in the interests of the mutual insurance companies of the state.

The mutual companies are said to expect to reap great advantages in the insurance field through the elimination of the stock companies, also expecting to cripple the state insurance funds. Commissioner Donaldson of the State Insurance Department is reported to have said that if this bill passes it will eliminate the 10 per cent. differential rates now enjoyed by the state fund. The state fund was granted authority to sell insurance at 10 per cent. less than other companies with a view of building it up. The Hess bill therefore might result in placing the state fund on a straight competitive basis with other companies.

Friends of the state fund, among them being some of the large coal companies, are supporting the Hess bill. They see that by means of this bill the state fund eventually will hold the compensation field to itself. This will mean monopolistic state insurance in this particular field and no doubt in time will spread to other lines of insurance.

A few days ago the Legislature passed and sent to Governor Sproul a bill designating what resources shall be set aside by companies for protection of holders of policies for workmen's compensation insurance. This bill allows mutual companies to set aside less reserves than stock companies, notwithstanding that mutuals have no assets.

On June 4, the Senate passed the McConnell bill granting authority to the insurance commissioner to ascertain whether rates made by insurance companies, individual associations or rate making bureaus are excessive or adequate and to determine "reasonable" rates in such cases. This would place insurance companies under direct control of the commissioner.

Senator Albert Davis of Scranton, on June 2, iptroduced a bill aimed at mine cave conditions in the anthracite field. The main provision of the new bill makes it unlawful for coal companies to damage cemeteries or disturb graves by mining operations.

Fairmont, W. Va.

The best indication of improving conditions in northern West Virginia sections was seen during the week ended May 31 in the decreased number of idle mines as well as in the increased number of cars loaded. In the Fairmont region proper there was an increase over the previous week, the total number of cars loaded being close to 5000 for the week. In April the total number of loads was only about 14,000 in all. A large factor in increasing shipments from northern West Virginia regions has been and was (during the last of May) the heavy tonnage for export; although it was apparent that more coal was being bought in all markets, judging from the increased western movement of coal. Decoration day, of course, tended to cut down the volume of coal mined and shipped during the week. Lake tonnage was somewhat increased. Cars were also more plentiful. No serious labor shortage has developed in the region. Prices are much firmer and further increases are expected in that respect.

Sentiment of the operators of northern West Virginia as to the resumption of cost sheets to be submitted to the Federal Trade Commission is being sounded out by Vice President George T. Bell, of the Northern West Virginia Operators' Association. This is a matter which will also come before the West Virginia Coal Association.

Charleston, W. Va.

With a larger production in West Virginia mines there has also developed in several producing regions of the state a car shortage most pronounced during the last week of May and in the first few days of June, interfering with the prompt shipment of coal particularly to tidewater and in some instances causing a shutdown of two days. Such a car shortage came just at a time when regions were striking their gait in response to a quickened demand confined to no particular section or market. Consumers in general had begun to realize the necessity of buying coal now; consequently further increases in tonnage from all regions was not confined to exports nor to railroad coal, but to all kinds of fuel, coke alone failing to move in any considerable quantity. In nearly every producing district mines were being operated throughout the week. The pressure of a demand from exporting sources made itself felt during the last few days of May and at the outset of June, more ships being available. The demand for West Virginia coal in the West, and particularly on the Lakes, continues to grow in proportion. With inquiries more numerous for coal and with some producers (especially in the smokeless regions) out of the market, prices have materially stiffened; run-of-mine in the Kanawha and Logan regions averaging from $2.10 to $2.50 a ton on spot sales and much higher in the smokeless fields. Labor is becoming somewhat scarce.

Under a steadily increasing demand, mines in the Kanawha region were, during the final week of May, being operated over a longer period per week; a scarcity of miners, however, limiting the running of mines to about two-thirds of the week. Consequently production during the last week of May was not over 60 per cent., or about 125,000 tons, although some operations were engaged throughout the week in getting out coal. In West Virginia the markets are beginning to seek the coal instead of the coal seeking the market, some companies no longer being in the market. Consequently prices are stiffening and much Kanawha coal is beginning to be sold around $2.50 a ton in connection with spot sales.

New River operations were unable to furnish the full quota of coal for which they had a market during the last week of May, owing to adverse transportation conditions. Cars were so scarce that in certain portions of this field mines lost two days out of the six, although warranted by orders on hand in running to capacity. Such a condition was extremely inopportune, as there were a number of vessels at tidewater waiting to be loaded with New River coal. Of course it was impossible under such transportation conditions to meet all requirements of general Western and Lake markets. At the same time a shortage of miners, amounting to about 25 per cent., also contributed to hold down production; it otherwise would have been up to capacity, market conditions causing spot coal to go over $3 a ton for run-of-mine in the New River region.

Springfield, Ill.

Miners, operators and school authorities, in conference at Springfield, Ill., went on record as favoring the apportionment of a part of the Smith-Hughes fund for vocational education of Illinois miners. Illinois has been allotted $400,000 for distribution among the industries for the training of workers, upon the appropriation by the state of an equal sum. At the meeting unqualified approval of the plan was given by Joseph C. Thompson, State Director of Mines and Minerals, and also by other speakers. When Thompson, however, said that every boy in the mines had an ambition to become a mine manager or superintendent, Peter Joyce, of Springfield, member of the sate Mining Investigating Commission, dissented. Union miners, he said, would oppose it if it was designed solely to manufacture mine managers. "What we want is technical education for all," he said. "The miners need greater knowledge of mines and mining that they may be better able to cope with the dangers which surround them at work. Heretofore the state and Federal governments have been anything but willing to encourage such training."

The conference adopted a resolution endorsing the bill pending in the Legislature for the appropriation of $10,000,000 to the state school distribution fund. This fund is now $4,000,000. The increase is intended to facilitate vocational instruction in mining communities.

President Frank Farrington of the United Mine Workers presided at the afternoon session. W. S. Deffenbaugh, specialist in city school systems of the United States Bureau of Education, spoke on: "Some Suggestion for Improvement of School in Mining Towns." F. L. Heehn, superintendent of Gillespie public schools, discussed: "What Industrial Occupation Should be Given to Regular Day Pupils in Mining Communities?" E. A. Wreidt, State Supervisor of Industrial Education, spoke on "State and Federal Aid for Practical Instruction in Mining." Coal operators of the district were represented on the program by President H. C. Adams of the Central Illinois Coal Operators' Association, who heartily approved the plan for vocational training. The action in favor of vocational training was unanimous.

PENNSYLVANIA

Anthracite

Pottsville—A local company recently started work on a new stripping for the Buck Run Coal Co. at its Darkwater colliery near St. Clair.

Scranton—It is stated that four buildings in a block on West Lackawanna Ave., of this city, were demolished on June 2 by surface subsidence over the workings of the Oxford mine of the Peoples' Coal Co.

Sunbury—The Philadelphia & Reading Coal and Iron Co., on June 1, paid $103,000 for land taxes for 1918 into the Northumberland County treasury. This covers assessments on coal properties held by the corporation, which are now assessed at an average of $200 an acre. There is an agitation for an increase in valuation of this property.

Shenandoah—The Lehigh Valley Coal Co. announces changes of officials at Packer Nos. 3 and 4 collieries. Reuben Ball, for 20 years inside foreman at Packer No. 4 is retired on account of failing health. Richard Kane, inside foreman at No. 3 succeeds Mr. Ball, while John Rudd, assistant inside foreman at No. 4 is promoted to the foremanship at No. 3.

The Lehigh Valley Coal Co.'s Packer No 5 colliery, which has been idle since February because of a scarcity of labor, resumed operations on June 2. The colliery is one of the largest in the district, and while the operation will be shorthanded, it is expected enough men are available to keep the place operating full time. All unemployed contract miners and laborers were given employment.

Wyoming—The Mount Lookout Coal Co. has filed appeals from the county assessment and valuation of its property in Wyoming, West Wyoming and Exeter bor-

oughs. They allege that the valuation is in excess of the price the property would bring at a bona fide sale. The value fixed on the coal was placed at $300 an acre for every foot of coal in thickness and lesser sums down to $120 a foot-acre.

Wilkes-Barre—In offering prizes for the best garden plots and the most attractive yards, the Lehigh & Wilkes-Barre Coal Co., is extending its policy of improving the homes and living conditions of its employees. During recent years the company has not only done away with the red houses of the old mining towns—row on row, all alike—substituting for them neat and individual homes, but has also developed whole villages of modern homes. These houses are leased at low rentals to its employees, rentals far below what would be ordinarily charged tenants for houses of the same grade.

Bituminous

Chicasaw—The Allegheny River mining Co., of this place, intends to install additional boilers and stokers for all boilers at its Chicasaw mine. Mr. G. White is superintendent at this plant.

New Bethlehem—Mr. James Sullivan is operating a small mine at this place but expects to enlarge the operation in the near future by putting in a siding and tipple in order to load coal onto railroad cars.

Library—The Montour No. 10 mine of the Pittsburgh Coal Co., which has been under construction for nearly a year, expects to commence shipping coal about July 1. This plant will be a big producer and has two slope openings. The coal will come to one tipple which is equipped with Marcus screens and picking tables. This operation is on the Montour railroad, near this place.

Uniontown—The Orient Coke Co. held its annual meeting at the plant in Redstone Township near this place on May 15. The following officers were elected: Julian Kennedy, president; Robert Bentley, first vice president; J. W. Kennedy, second vice president; J. O. Miller, secretary-treasurer, and R. M. Fry, general manager. The directors are Julian Kennedy, Robert Bentley, Youngstown, O.; J. W. Kennedy, J. O. Miller, Julian Kennedy, Jr., and David Davis, Pittsburgh, and R. M. Fry, Uniontown.

Waynesburg—A sale of Greene County coal took place here recently. An undivided one-seventh interest in 37 tracts of coal in Cumberland, Jefferson and Monongahela townships, owned by James M. Hustead, of Uniontown, was sold at sheriff's sale. The interest in the several tracts aggregated 453⅓ acres and the total consideration was $226,905.

Another sale aggregating 275 9/10 acres was purchased by W. J. Kyle, of this place, for the Cumberland Coal Co., of Pittsburgh; consideration $138,100. An interest, including 177 3/10 acres, was purchased by W. C. Montgomery, for Paul J. Bickle, of Cleveland, Ohio; consideration $88,805.

Pittsburgh—Negotiations for the sale of the J. V. Thompson estate have recently approached the final stages of a deal which may rank as the largest single transaction in coal lands. The trustees of the Thompson estate and the members of the J. V. Thompson Creditors' Committee have had conferences with the legal representatives of probable buyers. While there is much conjecture as to the identity of the buyers, the ultimate purchaser is generally supposed to be the H. C. Frick Coke Co., a subsidiary of the U. S. Steel Corporation.

On June 1 the name of the United Coal Corp. was changed to Hillman Coal and Coke Co., at which time the business of J. H. Hillman and Sons Co. was taken over. The general offices of the company are in this city. The following are the officers of the Hillman company: J. H. Hillman, Jr., chairman of the board; F. W. Guthrie, president; A. B. Sheets, vice-president; Ernest Hillman, vice-president; Thomas Watson, vice-president and secretary; Robert W. Flenniken, treasurer; F. B. Lockhart, Genl. Mgr. of sales, and M. D. Flanigan, asst. general manager of sales.

An important meeting was held on June 3 by the Pittsburgh Coal Producers' Association at this place. The coal situation as it is today and for the coming fiscal year was discussed by J. D. A. Morrow, vice-president of the National Coal Association; R. W. Gardiner, commissioner for the Pittsburgh Coal Producers' Association, and a number of the association members also took part in the discussion.

Branches of the National Coal Association have been established in Chicago, Cincinnati as well as Pittsburgh and soon one will be established in Washington, D. C. A general warning is being sounded by prominent government and other officials connected with coal production and distribution in regard to a serious coal shortage impending.

WEST VIRGINIA

Princeton—On May 28 the Virginian Railway exceeded all previous records; one train out of this place bound for tidewater was made up of 100 cars carrying 7922 tons of coal; this train was being moved east. The 100-car train was about 20 cars longer than the average train.

Fairmont—F. R. Lyons, of the Consolidation Coal Co., conferred with the division managers of this company recently; the purpose of this conference was to discuss problems of operation growing out of the changed conditions of the last few months. The division managers present were: C. H. Tarleton, of West Virginia; J. M. Gilbert, of Maryland; J. G. Smythe, of Jenkins, Ky.; E. R. Rice, of Van Lear, Ky., and S. Steinbach, of Pensylvania.

Welch—Officers were re-elected at the annual meeting of stockholders of the Panther Coal Co., Lathrop Coal Co., and the Leckie Collieries Co., held here on May 28. The president of all three companies is Wm. Leckie. Other officers re-elected were W. R. Graham, vice president of the Lathrop and Panther Coal companies; A. F. Leckie, vice president of the Leckie Collieries Co.; A. E. Jennings, secretary and treasurer, and A. F. Leckie, assistant general manager of the trio of companies.

Huntingham—Coal operators of West Virginia and eastern Kentucky are endeavoring to press into service about 20,000 new coal cars which were constructed under Government orders last year; since that time these unnamed cars have been standing idle on side tracks. The U. S. Railroad Administration purchased cars for a number of coal carrying roads for $3000 each; some of the cars were accepted by the Chesapeake & Ohio railroad but other carriers turned them down. The growing demand for coal makes the use of this equipment imperative, operators say, and a move is on foot to get them into service at once.

Morgantown—The seventh annual short course for miners will be held at the West Virginia University at this place from June 16 to July 26. Professor Callen will have charge of the course and he will be assisted by R. Z. Virgin and H. E. Gray—all connected with the university. The only entrance requirements for this course are the ability to read and write. There is no charge for instruction and no fees of any kind. Address R. Z. Virgin for further particulars.

OHIO

Wellston—The Wellston Hill Coal Co. has recently completed negotiations for the purchase of the properties of the Coalton Fuel Co., located in Washington Township. It is understood that the tract comprises a total of about 440 acres.

McArthur—Frederick C. Newberry, Jr., of Philadelphia, has purchased at sheriff's sale 7,019 acres of coal land in Clinton, Vinton and Elk townships, of this state, for which he paid $109,000. The lands have been inspected just recently by a legislative committee with a view of purchasing them for state mines.

Columbus—Public utility interests are discussing the Robinson bill, which has passed the Ohio House of Representatives and is expected to pass the Senate after the recess. Some profess to see an effort to bring coal mines under the authority of the Ohio Utilities Commission; coal mine owners are investigating the bill and having legal talent go over it.

ILLINOIS

Edwardsville—A new mine has been started south of this place by the Donk Coal Co., of St. Louis, Mo. The engineering and constructing firm of Allen & Garcia, Chicago, is connected with the work and it is understood that the plant will have a capacity of 5000 tons daily. It is planned to be a high class modern plant with a skip hoist. Operations commenced May 20 and contracts have been let for machinery. The plant should be producing by fall.

Divernon—The Madison Coal Corporation broke the record for hoisting coal for the second time during the month of May at its No. 6 mine at this place. It is stated that the first record was established on May 7 when a total of 4003.6 tons or the equivalent 1352 mine cars were hoisted. On May 24 the total tonnage raised to the surface from No. 6 shaft, during an 8-hr. day, was 4106.2 or 1376 mine cars. This company has 700 employees of which number 375 are loaders. The engineers at the throttle during the hoisting were, J. F. Woolford, Frank McVeigh and J. G. Larken.

KENTUCKY

Louisville—Some big coal land developments in eastern Kentucky are in sight as a result of a decision by the Court of Appeals, ordering dissolution of the Louisville Property Co., and appointment of a receiver. This organization is a subsidiary of the Louisville & Nashville Railroad Co., which has held large tracts in eastern Kentucky said to be approximtaely 75,000 acres. The company is reported to have blocked development, endeavoring to secure arrangements whereby all coal from the district would go over its lines. Minority stockholders brought action.

ALABAMA

Kennebunk—The Yolande Coal and Coke Co., Birmingham, has awarded contracts for electrical mining equipment, including hoisting machinery, pumps, etc., to be used in connection with the development of a new mining property. Contract has also been awarded for a new electrical haulage road for the works. The contracts are estimated to amount to $150,000. N. B. McClary is president and general manager.

Birmingham—At the annual meeting of the Alabama Coal Operators' Association held on June 3 the following officers were elected: George B. McCormack, president; Chas. F. DeBardeleben, vice president, and James L. Davidson, secretary-treasurer. All of these executives succeeded themselves in office. George G. Crawford, president of the Tennessee Coal, Iron and Railroad Co., was elected chairman of the executive committee, with George F. Peter, J. B. McClary, F. H. Crockard and Walter Moore as associate members.

The Corona Coal and Iron Co. has closed a contract with the Universal Coal Washer Co., of Birmingham, Ala., to erect a 600-ton washery at its No. 2 mine at Townley, Ala. The washer company will install Burks & Hayes jigs in the new plant which is to be ready for operation by Sept. 14.

MONTANA

Sheridan—O. P. Hood, chief mechanical engineer of the Bureau of Mines recently visited the sections of the Northwest having lignite deposits. The Government recently authorized the expenditure of $100,000 for a lignite experimental plant and it was with a view of investigating this territory for a possible site for such a plant that the trip was made.

Personals

O. C. Huffman has been appointed general superintendent of the W. E. Deegans Coal Co., in charge of the mines of this company on the line of the Virginian Ry. as well as on Coal River.

John Huns has been appointed superintendent of Mine No. 11 of the Jamison Coal and Coke Co.; this mine being known as the Lehigh operation of the Jamison company. He succeeds **John Malloy,** resigned.

H. L. Garbutt, for the last six years manager of the line material section of the Westinghouse Electric and Manufacturing Co. at East Pittsburgh, Penn., has been appointed manager of the supply division of the Westinghouse San Francisco Office.

H. C. Hawes, formerly manager for the Salt Lick Coal Co., has been made resident manager of the Wells-Elkhorn Coal Co., in charge of the Salt Lick and Black Diamond operations, succeeding W. C. Hawes, at one time manager of the Black Diamond Coal Co.

James W. Paul, secretary of the Mine Inspectors' Institute of the United States of America, has just returned to Pittsburgh from a trip to Indianapolis where he completed the arrangements for the holding of the decennial meeting of the institute, July 8-11, the announcements of which will soon be issued to the members. A good program

will be presented and all mine inspectors and deputies and assistant inspectors are urged to be present.

W. C. Tyler, formerly district manager for the Poole Engineering and Machine Co., has been appointed general sales manager in charge of all the selling activities of the company. On May 1 this company removed its general sales office from Baltimore, Md., to 50 Church St., New York City, where all correspondence pertaining to sales should be addressed.

James Inglis, president of the American Blower Co., of Detroit, Mich., sailed from New York recently as a member of a commission appointed to confer with a certain European industrial interest on post war conditions in the industry throughout the world. Mr. Inglis will also visit Belfast, Ireland, to confer with his associate in the blower business, **Mr. Davidson, of the Sirocco Engineering Works.**

A number of changes have been announced among the officials of the Mining Department of the Cambria Steel Co., of Johnstown, Penn. **Frank Horton**, former superintendent of Franklin mines Nos. 1 and 3 has been promoted to assistant superintendent, taking the place of **Joseph Lewis** who goes to Mariana, Penn. **David Malcolm** becomes superintendent of the Rolling Mill mine. **Duncan May** takes the place of Mr. Horton as superintendent of the Franklin mines.

William A. Holley, assistant general freight agent in charge of coal traffic for the Burlington railroad, resigned recently to accept the position of traffic manager for the Central Illinois Coal Traffic Bureau, with headquarters in Chicago.

This Bureau was organized recently by the coal operators in the Springfield District of Illinois, which produces approximately forty per cent. of the coal mined in the state.

This new organization is formed for the purpose of handling in a uniform manner all traffic matters of interest to the membership and their customers.

Obituary

James T. Armstrong died recently at the age of 65. He was formerly president of the Mansfield Coal and Coke Co. He was also connected with several banking institutions.

James Wrigley, senior member of Cutter-Wrigley Coal Co., died May 29 of heart trouble. Five years ago he was instrumental in the organization of this company, of which his son, Robert Wrigley, is now the president.

Coming Meetings

American Institute of Mining and Metallurgical Engineers will hold its fall meeting Sept. 22 to 26 in Chicago, Ill. Chairman Chicago meeting, Carl Scholz, 547 West Jackson Boulevard, Chicago, Ill.

American Society of Mechanical Engineers will hold its spring meeting at the Hotel Statler, Detroit, Mich., June 16 to 19. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

American Institute of Electrical Engineers will hold its annual convention at the Lake Placid Club, Adirondacks, N. Y., June 24 to 27. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

Northeast Kentucky Welfare and First Aid Association will hold a first-aid contest July 4 at Pikeville, Ky. Secretary, E. H. Sowards, Pikeville, Ky.

The Rocky Mountain Coal Mining Institute will meet in Salt Lake City the first week in July, 1919. Secretary, F. W. Whiteside, Denver, Colo.

American Society of Civil Engineers will hold its forty-ninth annual convention in St. Paul and Minneapolis, Minn., June 17 to 20. Secretary, C. W. Hunt, 33 West 39th St., New York City.

Mine Inspectors' Institute of the United States of America will hold its annual meeting July 8 to 11 at Indianapolis, Ind. Secretary, J. W. Paul, Pittsburgh, Penn.

Trade Catalogs

Vesuvese. Swan & Finch Co., New York, N. Y. Folder. Pp. 4; 3½ x 6½ in.; illustrated. Notes the application of this waterproof lubricant to wire rope, exposed gears, etc.

The Steam Motor. The Steam Motors Co., Springfield, Mass. Bulletin No. 5. Pp. 24; 8½ x 11 in.; illustrated. Notes the various points of the design and application of this steam turbine.

Electrical Insulation. Chicago Mica Co., Valparaiso, Ind. Catalog No. 26. Pp. 48; 6 x 9 in.; illustrated. Describes fully the company's line of standard and special mica insulation in its various forms.

Zelnicker's Bulletin—No. 263. W. A. Zelnicker Supply Co., St. Louis, Mo. Folder; Pp. 4; 3¼ x 8½ in.; illustrated. Describes portable hand power pipe threading machines; steel tray bodies, special lamps, etc.

Boss Mixers. Boss Hoists—Elevators. American Cement Machine Co., Inc. Catalogs Nos. P20 and H20, respectively. Pp. 10 each; 8½ x 11 in.; illustrated. These catalogs describe concrete mixers and hoisting engines and elevators used by builders.

Chain Drives, by J. S. White. Morse Chain Co., Ithaca, N. Y. Pamphlet; reprint from 1919 Year Book of National Association of Cotton Manufacturers. Pp. 12; 6½ x 9 in.; illustrated. A short synopsis of the general subject of chain driving showing application to textile industries.

Metal Melting Pots. Soldering Irons. Sockets to Harmonize. The Cutler-Hammer Manufacturing Co., Milwaukee, Wis. Folder—pp. 6; 3½ x 6 in.; illustrated. Booklet—pp. 8; 3½ x 6 in.; illustrated. Folder—pp. 4; 3½ x 6 in.; illustrated. These publications describe specialties of the Cutler-Hammer company.

Industrial News

DuQuoin, Ill.—The Victory Collieries Co., of this city, operating the Victory mine at Tamaroa, north of here, has recently moved its main office to Chicago. This company formerly went under the name of the Paradise Franklin County Coal Co.

Steubenville, Ohio—Rapid progress is being made in the opening of the new Rigby mine of the Akron Coal Co. here, and it is planned to have the plant in operation as quickly as possible. The J. W. Williamson Contracting Co. of Columbus, Ohio, is doing the work.

Paintsville, Ky.—The Wells-Elkhorn company is planning the development of 2000 acres of coal land on Beaver Creek where it will mine the Elkhorn seam. At the Salt Lick and Black Diamond mines of the company new mine openings will be made. The company is under the management of C. O. Messenger.

Huntington, W. Va.—A $100,000 concern has been organized in this city for the purpose of manufacturing mine equipment of various kinds. H. T. Lambert of this place is at the head of the company which will have its plant here. Associated with Mr. Lambert are H. G. Clark, Gladys Baker, C. F. Cunningham and R. M. Davis.

McCuneville, Ohio—About July 1 the Kehota Mining Co., opened another stripping operation here near Shawnee. With the three stripping operations of this company going, the capacity will be about 5000 tons daily. The product is sold through the Pittsburgh & Bessemer Coal Co., of Columbus.

Childs, Penn.—The coal mine owned by H. R. Stone & Co. changed hands recently, when the interests were purchased by W. T. Spruks of Scranton. There is a small breaker on the tract, but it is stated that the new owner intends to make extensive improvements, enlarging the breaker and the mine so as to ship coal on a larger scale.

Beckley, W. Va.—The Simrall Coal Co., recently incorporated, has completed preliminary survey work in connection with the proposed development of its properties in the Winding Gulf district in Raleigh County. Dr. George Hogg is president; P. M. Snyder, vice-president, and F. T. Drumheller, secretary-treasurer.

Charleston, W. Va.—Surveys have been made for the plant of the Fryland Coal Co., which is to operate near Cedar Grove, in Kanawha county; no time will be lost by the company in proceeding with construction plans. The company was recently organized by William T. Slicer of Charleston; C. G. and Johnson Fry, of Ceredo; Floyd Chapman of Huntington and Charles E. Howland, of Nitro.

Carlinville, Ill.—Development of a large tract of coal land in Macoupin County will soon be started by the Sinclair Oil and Refining Co. The land is next to the coal rights purchased several years ago by the Union Coal Co. It is said that another company known as the Hunt Construction Co. will also develop the Sinclair field and that the two large mines will each have a daily capacity of 4000 tons.

Steubenville, O.—The Commonwealth Coal Co. has recently completed negotiations for the purchase of the mines and holdings of the Genree Coal Co., located in the vicinity of Martins Ferry, W. Va., for a consideration of about $40,000. It is understood this company is planning improvements to increase the present capacity. This company recently acquired the holdings of the Burlington Coal Co., located in the same section, for a consideration of about $60,000.

Minneapolis—Representatives from the Northwest appeared before Robert Wright of the Federal Railroad Administration recently to protest a freight advance of 30c. a ton on coal shipped from Illinois mines to the Northwest. Minnesota, the Dakotas, Wisconsin and northern Iowa, get coal from Illinois. It is estimated that 9,000,000 tons will be shipped to this section this year. The new rate which is being opposed is supposed to go into effect July 1 and the freight increase amounts to $2,700,000.

Du Quoin, Ill.—Activity in coal development in the vicinity of this place continues. Announcement is made of the sinking of a new shaft about two miles southwest of Du Quoin to be operated by the J. R. Crowe Coal and Mining Co., of Kansas City, Mo. When completed it is expected that the new plant will employ from 800 to 900 men. Charles Duncan, of Pittsburgh, Kan., completed the drilling of this property about a year ago. This new plant will make a total of seven shaft mines and one stripping within a radius of five miles of this town.

Birmingham, Ala.—The stockholders of the Railway Fuel Co., will meet in Birmingham, June 16, at which time they will vote on the proposition of issuing a first mortgage on their coal properties to secure a loan of not exceeding $1,000,000. Consideration will also be given to increasing the capital stock of the company $150,000. The Railway Fuel Co. owns extensive coal properties in Walker County, near Parrish, Ala., and is producing coal from a mine developed about a year ago. The company is allied with the Southern Railway interests and the entire output of the mine is used by the lines of that system.

MARKET DEPARTMENT

EDITED BY ALEX MOSS

Weekly Review

Bituminous Market Slowly Improves—Shortage in Late Fall If More Consumers Do Not Stock Coal—Anthracite in Good Demand—Domestic Sizes Scarce—Steam Sizes Hard To Move

ABSOLUTELY devoid of any untoward incident, the coal market this week presents much the same characteristics that have distinguished it during the past month or more. The bituminous coal operators are slowly winning a more advantageous position, while the producers of anthracite are enjoying what gives promise of being an unparalleled summer business.

Again it must be emphasized that unless consumers take in more soft coal during the next few months than they have been stocking, there will be a coal shortage in the late fall. The mines must be stimulated to produce maximum tonnages, for output is growing smaller. Bituminous coal production is now 30 per cent. of the production in the same period last year. The output of soft coal in the last week of May, estimated at 7,930,000 net tons, is more than 2,600,000 tons lower than the production of the corresponding week in 1918.

From the figures at hand, it would appear that the production of bituminous coal this year cannot be greater than 500,000,000 net tons. At the beginning of the calendar year investigation disclosed that there was a reserve stock of bituminous coal in the hands of consumers of about 30,000,000 net tons. Most of this reserve is now gone. There is sure to be a scramble for coal late this year—and prices will soar.

The domestic grades of soft coal are holding up well in price, but steam coal at the present time is going at all sorts of prices. Few contracts are reported.

Anthracite production during the week ended May 31 dropped to 1,285,000 net tons. Stove, egg and chestnut continue to be in urgent request. The steam sizes, such as pea, buckwheat and barley, are hard to move and price concessions are being made to dispose of them.

WEEKLY COAL PRODUCTION

The production of bituminous coal, which gained steadily for four weeks and reached a maximum since Apr. 1 of nearly 9,000,000 tons in the week ended May 24, declined in the last week of May to 7,930,000 tons, a decrease of 9 per cent. The production in the last week of May, 1919, was more than two and one-half million tons, or 25 per cent. below that of the corresponding week of last year. The production of bituminous coal in the first five months of 1919 is 177,340,000 tons. The production in the corresponding period of 1918 was 234,632,000 tons, which exceeds the production for the same period of this year by 57,000,000 tons, or 24 per cent. In the six years 1913 to 1918 the percentage of annual output of bituminous coal in the first five months of the calendar year averaged 40 per cent., the lowest being 36 per cent. in 1915 and the highest being 41 per cent. in 1914, in 1916 and in 1917. If the production of the first five months in 1919 represents 40 per cent. of what will be mined this year, the production for 1919 is thus indicated to be but 446,000,000 tons; if, as in 1915 the output in the first five months is 36 per cent. of the total for the year, an output of 495,000,000 tons is indicated for the calendar year 1919. These facts appear to indicate that the production of bituminous coal this year cannot be greater than 500,000,000 net tons. Whether this quantity added to the surplus stock on hand at the first of the year, estimated around 30,000,000 tons, will be sufficient for the needs of the country depends upon whether general industrial activity recovers sufficiently to approximately equal that of the later part of 1916 and the early part of 1917.

The production of Pennsylvania anthracite in the week ended May 31 is estimated at 1,285,000 net tons compared with 1,656,000 net tons for the week ended May 24 and 2,005,000 tons for the last week in May, 1918. From the records for the first five months of 1919 an output of approximately 80,000,000 net tons is indicated for 1919, a decrease compared with 1918 of 9 per cent., and a decrease compared with 1914, the lowest output recorded in the past six years, of more than 8 per cent. The rate of production of anthracite in the first nine weeks in the present coal year has been approximately 1,600,000 net tons compared with 1,940,000 net tons for the same period of last year and 1,900,000 tons for the calendar year 1918. The rate of production of anthracite has shown a tendency to increase slightly and can be increased even more if domestic consumers will enter the market to even a greater extent for their supply of household fuel for next winter.

Production of beehive coke in the United States in the week ended May 31 is estimated at 264,645 net tons compared with 250,810 net tons in the week ended May 24, and 582,204 net tons in the week ended June 1, 1918. For the calendar year to date the production is estimated at 8,481,000 tons compared with 12,547,000 tons for the corresponding period of last year. Excepting West Virginia, all beehive coke districts recorded improvement in production in the last week of May, but in all districts the output for the week and for the year to date is much below that of the corresponding period of last year.

Bituminous coal dumped at the lower lake ports, including vessel fuel, for the week ended May 24 is reported as 906,201 net tons compared with 911,309 tons in the week ended May 17, 1919, and 713,126 net tons in the week ended May 25, 1918. The season's dumpings to May 24 are 4,038,358 tons compared with 3,556,137 tons in the corresponding period of last year. Shippers of lake coal, particularly those shipping on their own account, are taking advantage of the slack demand in the central competitive markets to forward their supplies to the head of the lakes.

BUSINESS OPINIONS

The Iron Age—The activity in the steel market continues in an encouraging way, without broadening to any marked degree. Mill operations are on a slightly increased scale. Some phases have been overrated, particularly the amount of third quarter and second half buying, which is quite moderate. Price irregularities continue, but the schedule of Mar. 20 holds its place as the market standard. The concessions are in sheets, hot rolled strips, steel bands and some other of the lighter products.

American Wool and Cotton Reporter—There has been heavy rain in the cotton belt and unless the weather changes a number of the fields will have to be abandoned as the crop is getting grassy. An advance in prices last week caused certain hesitation and the buying has been rather scattered. This advance also affected the dry goods market as it has caused buyers to hesitate to pay the high prices that the mills have to ask.

Marshall Field & Co.—Current wholesale distribution of dry goods is running slightly ahead of the large volume of the corresponding week a year ago. Merchants are visiting the market frequently and were in the house in greater numbers compared with the corresponding week of 1918. Retail business continues excellent. Orders from salesmen on the road for both immediate and future delivery are much greater in volume than for the corresponding week last year. Collections are satisfactory.

Atlantic Seaboard

BOSTON

Signs of improved market. A distinct upward swing needed, however, before buyers put much faith in prices for fall and winter. Export prices advance at Hampton Roads. New York and Philadelphia pier markets very dull. Increasing allocations of steamers for over-sea coal trade indicate heavy movement later. Anthracite demand continues. Boston retail prices advance.

Bituminous—Almost it would seem that prices are on the point of changing. There is nothing tangible to report as yet, and only in scattered instances is there any less anxiety to place spot tonnage, but beyond question the outlook for the near future is much improved. The recent Navy bids and the fact that relatively so small a tonnage was offered have shown how much better is the feeling in the trade as to prices for fall and winter delivery. Some shippers have now definitely declined to take more contracts until the general situation is somewhat cleared up, and from this attitude on their part it will only be a short period, probably, before buyers show a belated interest in contract prices.

There may be an absence of price movement until July, for much will depend upon the extent to which consumers will enter the market. The undertone is distinctly favorable to higher prices for season delivery and it is only a matter of a few weeks now before spot quotations will be on a higher level than has obtained recently. A large number of buyers who have been "trying coals" have now about made up their minds to purchase, and it is likely the next fortnight will disclose some more or less active buying. This market, however, will be still confined very largely to Pennsylvania grades, both all-rail and by water, for the Southern smokeless coals are on the same high basis alongside that has prevailed for several months.

Buyers in general find it hard to reconcile the low prices so recently submitted to the railroads with the contract figures now being asked by the trade. It is as if various operators had now decided they

had sold all the low-priced coal necessary and for the rest of their tonnage were determined to get a better return. Of course, the railroads have not been the only beneficiaries, but railroad purchases have been well advertised and their effect upon the current market has been quite pronounced. It will take a distinct upward swing to convince New England buyers that a shortage next winter is a real possibility.

It is rumored here that export prices at Hampton Roads have been advanced from $5.60 to $6 f.o.b. ship, and it is known that certain of the smaller agencies who were naming spot prices down to $4.69 have now withdrawn quotations that were below $5.14 for coastwise business. For the first time in months a few steamers have met with delay at the loading piers, and although the detention has not been at all serious it gives point to firmer quotations. Distinctly there is a better feeling among the Pocahontas and New River shippers, and while New England apparently has little to do with it the factors here are encouraged by the prospect for export business which will doubtless have some reaction here. Distributors of the smokeless coals in cities like Boston and Providence have been closing up retail business lately in more volume than at any time thus far this season. The city of Providence bought 13,000 tons Pocahontas this week at $9 per net ton of 2000 lb. delivered by truck.

All-rail there is better inquiry than a fortnight ago. A few large buyers are coming into the market, but they are very coy about it and it is difficult to get much line on prices.

At New York and Philadelphia the demand for coal over the piers continues light. Shippers who submitted prices to the Navy Department are still in doubt as to the tonnage that will be required and this makes for a good deal of uncertainty as to sales for future delivery. There are those who think that the strong arm of the Fuel Administration will be made use of to get the Navy Department's stated quota. At the same time the spot market is listless and prices are about on the same level as for weeks past. There is some difficulty over arranging for barge transportation on contract through the winter and that has a depressing effect on efforts to arrange for contract coal. To an increasing extent shippers are insisting upon labor clauses in all contracts.

Perhaps the biggest factor in trade prospects is the amount of tonnage being allocated for oversea shipment. It is understood these allocations are to be steadily increased from month to month because of the heavy movement of American coal that will be absolutely required to keep Italy and other countries sufficiently supplied to enable industries and service plants to function properly. Taken together with labor shortage in the Pocahontas and New River districts this will probably mean a steady drain of a very large tonnage of the smokeless coals from Hampton Roads.

Current quotations on bituminous at wholesale are about as follows:

	Clearfields	Cambrias and Somersets
F.o.b. mines, net tons	$2.15@2.75	$2.75@3.35
F.o.b. Philadelphia, gross tons	4.27@4.95	4.95@5.50
F.o.b. New York, gross tons	4.62@5.29	5.29@5.85
Alongside Boston (water coal), gross tons	6.10@6.85	6.90@7.35

Georges Creek is quoted at $3.20 per net ton f.o.b. mines.

Pocahontas and New River are being quoted at $4.69@5.14 per gross ton f.o.b. Norfolk and Newport News, Va. Alongside Boston the same grades are being offered at a range of from $7.10@7.34, and on cars Boston and Providence at from $7.50@7.90 per gross ton, the latter being the contract price f.o.b. cars for deliveries to April 1.

Anthracite—The city markets in New York and Philadelphia have eased just enough to make loading for New England a shade less difficult. This has been noticeable only since the 10c. advance became effective June 1 and it remains to be seen whether the same condition will hold true the latter part of the month. Egg, stove and chestnut are still the sizes in greatest demand and there is continual detention at most of the piers. It is expected dispatch will improve this month and the various factors will make every effort to get coal forward to this territory where dealers' stocks are at a minimum. Retail demand is still insistent, and there are as yet no signs of letup. The Boston retail dealers advanced prices on June 2 50c, to $12 for egg, stove and estnut, per ton of 2000 lb., sidewalk delivery. Broken and pea were allowed to remain at the May figures.

NEW YORK

Demand for egg, stove and chestnut continues. Supplies short and retail dealers receive barely enough to keep their help employed. Household consumers want their coal before vacation time. The steam sizes move slowly, and prices are being shaved. Bituminous tidewater market dull. Little coal moving, but dealers are optimistic. Large consumers soon to come into the market.

Anthracite—The anthracite market continues strong, with the so-called Independent domestic coals bringing premiums and the steam coals being let go at large concessions. The slogan, "Buy Your Coal Early," and the publicity of the various coal agencies, to say nothing of the warnings issued by the various Government departments, have all had their effect upon the consumer; and instead of the feeling of a few weeks ago that there was no hurry on their part, consumers are now anxious to get their bins filled.

Shipments are so slow at this port that retail dealers receive hardly enough of the larger sizes to keep their help busy, while their books contain orders enough to keep them busy for the next few months. The heaviest pressure on the dealers will come this month, as most household consumers desire to leave the city and are desirous of receiving their winter fuel before their departure.

The increase in production hoped for by the trade does not materialize to the satisfaction of the dealers because of various conditions, principally the lack of certified miners and the many holidays.

Stove, egg and chestnut, in the order named, continue to be strongest in demand and those in a position to speak hesitate to give their opinion as to what might be the conditions next fall and winter knowing that the operators are not storing any of these sizes.

Pea coal is plentiful, but it is not necessary to use much force to effect sales as most dealers are willing to take some in order to get the larger sizes. The buckwheat coals are long and prices are easy in nearly all grades. A considerable tonnage is being stocked by the large producers and, so far as they are concerned, little is heard about concessions; but for the so-called Independent product there has been, so reports have it, much cutting of prices. Manufacturing plants are well stocked and there is a large volume of the three small coals in cars along the roads. Some grades of buckwheat are being quoted at the mines around $2.75, while for rice $2.25 has been heard and from $1.25 to $1.50 for barley, depending upon the quality of the coal.

During the period from May 30 to June 6 inclusive there were dumped at the local railroad terminals 5380 cars of anthracite as against 4366 cars the previous week, an increase of 1014 cars. During the 30 days of May there were dumped at the piers 26,138 cars of anthracite as compared with 19,448 cars in April and 6439 cars in March.

The city will soon be in the open market for nearly $100,000 worth of coal for the Fire Department, and Bellevue and Allied Hospitals. This is necessary because of the high prices submitted at the opening of bids on May 14, which in most instances were higher than the appropriations made for them.

Current quotations, white ash, per gross ton at the mines, f.o.b. tidewater at the lower ports, are as follows:

	Mine	Company Circular
Broken	$5.95	$7.80
Egg	6.05	7.90
Stove	6.30	8.15
Chestnut	6.40	8.25
Pea	5.00	6.75
Buckwheat	3.40	5.15
Rice	2.75	4.50
Barley	2.25	4.00

Bituminous—The local trade continues to be optimistic even in the face of the demoralized trade conditions here. There is little demand and free coals move slowly, yet notwithstanding these conditions there are tradesmen who are talking better prices within the next few weeks.

Their hopes are based on the knowledge that manufacturers as a rule have been burning high-priced coal bought early last winter and that they are now able to see the bottom of their bins. This condition will drive consumers into the market soon, and those who have failed to close contracts will have to take what the market offers.

Existing conditions are anything but favorable. The tidewater situation is particularly unsatisfactory. There is practically none of the free coals moving and embargoes are the rule, not because shippers are sending large tonnages forward, but because of the lack of demand. The coal coming to tidewater would readily be absorbed under normal conditions, but with the slow buying someone stands a chance of losing out because of extra charges.

There is a strong desire on the part of some buyers to close contracts, but operators are in no hurry to take on additional burdens, especially for the better grades, even though the prices offered are strong and tempting. They are not so sure as to what might be expected from labor.

Conditions along the line are in much better shape than locally. Prices are strong and there is a better demand. Here quotations on coal in Pools 1, 9 and 71 range from $2.25 to $2.75, based on mine prices; Pool No. 10, around $2.20; and Pool No. 11 around $2.

With so many large consumers running low of coal indications point to an active demand in the early fall and a big shortage in production to be overcome.

There were dumped at the local railroad piers 6511 cars of bituminous during the period May 30 to June 6, inclusive, as compared with 5378 cars the previous week, a gain of 1233 cars. During May there were dumped 25,271 cars of bituminous as compared with 20,708 cars in April and 11,516 cars in March. There were 4664 cars standing on tracks at the docks on June 6.

Quotations on the various grades, mine price, for spot and contract delivery, range as follows:

	Spot	Contract
South Forks	$2.90@$3.25	$2.95@$3.50
Cambria County (good)	2.75@ 2.95	2.95@ 3.25
Clearfield County (good)	2.50@ 2.75	2.80@ 2.95
Reynoldsville	2.50@ 2.75	2.75@ 2.95
Quemahoning	2.65@ 2.85	2.95@ 3.10
Somerset County (best)	2.50@ 2.75	2.95@ 3.10
Somerset County (poor)	2.00@ 2.35	2.50@ 2.75
Western Maryland	2.25@ 2.50	2.50@ 2.75
Fairmont	2.00@ 2.25	2.35@ 2.50
Latrobe	2.10@ 2.25	2.25@ 2.40
Greensburg	2.25@ 2.35	2.35@ 2.60
Westmoreland ¾-in.	2.60@ 2.75	2.60@ 2.75
Westmoreland run-of-mine	2.35@ 2.60	2.35@ 2.65

PHILADELPHIA

Anthracite production fully absorbed. Torrid weather slows retail demand. New orders from consumers decrease. Stocks on hand light, except pea. Good buying expected all summer. Slight falling off in egg demand. Stove extremely short, but not in moderate supply. Pea being stored by dealers. Steam sizes quiet, with some of all sizes going to storage. Collections good. Bituminous displays slight activity. Prices firm.

Anthracite—The torrid weather of the past week, with the temperature going beyond ninety on successive days, has apparently made the dealers less eager in their call for increased shipments. It may be that many of the retailers have exaggerated their needs and now find they have been able to clean up most of their orders much earlier than they thought. We have interviewed quite a number of dealers the past few days and most of them admit they expect to deliver every order on hand during the present month. Practically every dealer states that the new business being booked is very light.

Most yards contain only a small tonnage of egg, stove and chestnut, and the dealers will surely continue to buy until they have capacity stocks; in fact all representative dealers have so expressed themselves. It has been pointed out, however, that when deliveries fall off it requires no extraordinary tonnage to fill the several hundred yards located here, the majority of which are of but small capacity.

Opinions vary as to how the different family sizes will hold up during July and August. It is taken for granted that none of them will cause any concern until then. When the situation is analyzed, though, we believe that the demand for coal all summer will be heavy, much more so than normal.

Egg at this time is commencing to show a slight falling off, and while a substantial demand continues it will hardly remain that way throughout the summer. This will cause no uneasiness to the shippers, as the New England market will absorb all of the surplus. It will be recalled that New England was slow to respond to the buying movement this spring, but now that it is under way coal cannot be sent there fast enough to suit the dealers.

Stove remains extremely short, and most dealers are embarrassed for the want of it. They claim that practically every order they receive calls for at least a part of this size, and as they are behind in their deliveries it is causing their customers to withhold payment of their bills pending the completion of their orders. With little or no stove in most of the yards and an abnormal demand from all other markets, it cannot be seen how the requirements are to be filled before fall, by which time it is sure to be renewed most vigorously.

Chestnut has been shipped here much more freely than either egg or stove, and as a consequence most of the urgent cases have been cared for. The dealers have small stocks of this size, but as they now seem to have filled most of their orders they are not quite so insistent in their demands for it; in fact, some shippers believe they may need business for chestnut before the fall orders begin to arrive.

The shippers continue to hold orders for pea coal sufficient to take up the production several weeks in advance, but it must be said that the dealers are not disposing of their tonnage as rapidly as it is being received. Quite a stock is accumulating and a number will be compelled to order the suspension of shipments before many weeks. There seems to be a possibility of the big companies, who without question will hold to their circular price, being compelled to store this size before it comes into its own in the fall. If this happens there is a likelihood, of which we have heard fairly well founded rumors, that the dealers will be charged about 50c. a ton to cover the expense of storing and picking up. This is borne out by the fact that one of the large companies on a small quantity of prepared sizes recently picked up made a charge for this service.

There is no particular activity in the steam sizes. A good tonnage of buckwheat is being taken and some of the smaller shippers claim they have little of this size that is not under contract. The larger producers are still placing a small tonnage in storage and it is believed this will increase up to a month or more. There is a general feeling broadcast that the industrial revival cannot be long delayed and that beginning with the fall there will be a heavy demand for all steam sizes. Most of the present quantity of buckwheat being sold is being taken in by plants in anticipation of car shortage and other difficulties during the fall and winter. There is no change in the demand for rice and barley. While a good tonnage of rice is being shipped on contracts, there are few sales outside of this, while practically the only outlet for barley now is the city pumping stations, the contract for which was recently awarded to the leading anthracite company at a price 75c. under present quotations.

Shippers report that collections are good. While the accounts are not so closely collected as they were in war times, still it can be said that there is less money outstanding than for several years at this time of the season. Inquiry among the retailers develops that they are gradually giving more credit than they had expected, but they all claim it is only for a short time and is extended to gilt-edge customers.

Bituminous—There is little action in the bituminous trade. The production is about the same as it has been for a couple of months past, most of the output being applied on contract business. It is true that with the settlement of the railroad fuel problem there has been a greater number of inquiries from consumers for both contract and spot coal. Some companies have taken the stand that they have about all the contract business that they desire to handle and do not care to commit themselves to any further tonnage, as they want to be in the position of having some free tonnage when the expected boom actually arrives. Even as it stands now the good coals are hard to get and it is not going to take a very greatly increased general demand for fuel to make the pinch felt. A survey of the plants throughout the city shows gradually decreasing stocks and a frequent tendency on the part of buyers to add to them when they can get the coal they want. There have been very few price fluctuations, the quotations holding closely within the range of the past six weeks.

BALTIMORE

Little business in soft coal. Rumors of large export contracts. Anthracite scarce.

Little business in bituminous was noticed during the week, while there was evidence of increased activity in the export business. Local business was confined to small spot tradings with prices holding fairly firm and continuing around $2.75 for the best grade of fuel. Some trading in the better coals was done as low as $2.50, but most of it sold around the $2.75 mark. Contracting is still being held back, although buyers are being warned the market is liable to go up rapidly and that unless they evidence a tendency to get under cover many firms will find themselves short when the open market becomes light and there is little coal to be had. Contract figures are slightly above the present open market prices. The opinion here is that mines will not increase production until there is sufficient contract business to warrant a fair price for their product. No change was noted in the price of medium and cheap grade fuels, $2.30 being the top price for the former and under $2 for the latter.

The trade heard a rumor during the week that one of the large corporations had been able to close a contract for export amounting to about 3,000,000 tons. It was impossible to verify the report, but it was gossiped pretty well about the city. In most quarters it was taken for granted that it was O. K. South American ports, Sweden, Switzerland and Holland were points to which 28,414 tons of cargo and 3399 tons of bunker coal were carried during the past week.

Receipts of anthracite continue light, and the dealers here are hard put to it to handle the situation in view of the fact that their April orders are still undelivered. The dealers will likely announce a 25c. increase in the price of hard coal to householders on July 1, there being no change to date in the April schedule.

Lake Markets

PITTSBURGH

Runaway market predicted if consumers do not stock up.

Coal operators of the Pittsburgh district express anew their conviction that there will be a coal shortage late in the year. This was brought out forcibly at the last monthly meeting of the Pittsburgh Coal Producers' Association. J. D. A. Morrow chanced to be present and made an interesting address, referring to the fact that the country's coal production thus far this year is 30 per cent. short of production in the same period last year. The Pittsburgh district operators state that if consumers do not take more coal during the next few months a shortage will develop late in the year which will produce a runaway market, and this the operators wish to avoid for various reasons, one of these being the sentimental influence it would exert on wage scale negotiations for the period beginning Apr. 1, 1920.

Coal consumers are acting conservatively and evince no disposition to lay in stocks of coal, although before the coal scarcity of the past two years that was the usual procedure. Excess stocks that consumers held at the close of the war have now been eliminated and current buying has increased somewhat, though it is still only for current consumption. The steel industry shows no further decrease in activity, and there is perhaps a slight increase in mill operations. Lake shipments from the district are fairly heavy and are running at a rate that will readily make up the district's quota for a 20,000,000 ton movement up the lakes for the season. Coal production in the district is in the neighborhod of 60 per cent. of capacity.

Slack is easier in the market while prepared sizes are a shade firmer and mine-run is unchanged. Mines selling slack and prepared coal claim to be securing a shade more than the mine-run average. We quote: Best grades gas coal: Slack, $1.65 @1.85; mine-run, $2.35; prepared sizes, $2.60@2.70; Steam: slack, $1.50@1.70; mine-run, $1.90@2.35, per net ton at mine, Pittsburgh district.

TORONTO

Coal situation easier. Dealers overtaking delayed deliveries. Less fear of shortage. Bituminous quiet. Industrial crisis over.

The coal situation is considerably easier. Supplies of anthracite are coming forward from the mines in about normal quantities and dealers are gradually overtaking deliveries in arrear. New orders are only taken subject to prices prevailing at time of delivery. There is less fear among consumers of a shortage, and business is getting on a more satisfactory basis. Bituminous is little called for, owing partly to extensive strikes, but the industrial crisis is now over and market conditions are likely to show improvement in the near future.

Quotations for short tons are as follows:

Retail:	
Anthracite, egg, stove, nut and grate	$11.50
Pea	10.00
Bituminous steam	8.25
Slack	7.25
Domestic lump	10.00
Cannel	11.50
Wholesale f.o.b. cars at destination:	
Three-quarter lump	5.75
Slack	4.56

BUFFALO

Slight changes in bituminous trade. Consumers still hold off. Anthracite in great demand. Shippers trying to keep lake loading up

Bituminous—Consumers do not seem to be interested in coal at any price. Jobbers say it requires a good salesman to do business on the road, and that it is almost useless to stay in one's office and attempt to do business. Industries that use steam coal are in no condition to buy lavishly, and in addition the idea still prevails that prices will come down.

Bituminous prices are not steady, quotations remaining about as last week: $4.55 for thin vein Allegheny Valley sizes; $4.45 for Pittsburgh and No. 8 five-quarter lump; $4.50 for same, three-quarter; $4.05 for mine-run and $3.65 for all slack, per net ton, f.o.b. Buffalo.

Anthracite—The situation is much the same, except that the hot spell has discouraged ordering somewhat and consumers appear to be filled up, so far as summer stocking is concerned. Users of the chestnut size usually do not buy much till fall, as they are mostly poor people who move a good deal and buy coal only when it is needed. This size of anthracite is therefore more plentiful than either stove or the larger sizes of hard coal.

There is a general shortage of anthracite. Mining suffered during the holiday, almost three days being lost. There is a scarcity of men and it is hard to catch up when mining once gets behind. The winter supply is still a problem. It may be adequate but everybody fears it will not. Much depends on the winter, but no restrictions are likely to be imposed.

The prices of anthracite advanced 10c. a ton on some sizes June 1, and are now quoted as follows:

	F.o.b. Cars, Gross Ton	At Curb, Net Ton
Grate	$8 65	$10.35
Egg	8.65	10.35
Stove	8.90	10.40
Chestnut	8.90	10.60
Pea	7.20	9.25
Buckwheat	5.80	7.85

The showing in the lake trade is better, though it is feared that it cannot be kept up if the rail and local demand continues. The amount loaded for the week was 102,-125 net tons, of which 13,100 tons cleared for Chicago, 24,000 tons for Milwaukee, 6300 tons for Manitowoc, 3400 tons for Sheboygan, 1825 tons for Sault, Can., 1800 tons for Sault, Mich., 22,500 tons for Fort William and 15,200 tons for Duluth-Superior.

Freight rates continue at 50c. to Chicago and Sault, 47½c. to Milwaukee and Sheboygan, 42½c. to Manitowoc and Fort William and Duluth.

CLEVELAND

Growth in demand is slow, but it is steady and reassuring. Slack is gaining strength constantly, and it is expected that the stockpiles at the mines will be cleaned out by early fall. Many of the larger industrial users of coal now place August as the

time when they again will be operating at 100 per cent. Domestic consumers are still buying heavily, especially of Pocahontas.

Bituminous—Each week sees more consumers of steam coal entering the market and while their buying is of small proportions, it is just that much more than it has been. Last winter's accumulations now are practically out of the way, and the coal being bought today represents actual requirements. Business appears to be picking up gradually, but the pull seems to be hard. In several cases fairly large users of steam coal have foreseen a sudden inflated demand, with consequent soaring of prices, a few months ahead, and are buying while they consider the buying good. The large steel mills in the valley believe the beginning of August will see their order books jammed. The general opinion in Cleveland, too, is that about 60 days must elapse before business becomes really pressing again.

Practically without exception eastern and southern Ohio operators are bulls on the market, and mine operations are being speeded up. The lake trade continues to take all that is sent to the Lake Erie ports. In seeking to market all the coal they can in the lake trade operators are finding themselves pinched on labor. It is safe to say every operator could use at least 20 per cent. more mine workers. The foreign element especially is becoming restless, and is not producing; the greater part of it is awaiting steerage quarters for Europe. Cars, too, appear somewhat short despite the big surplus reported by the Railroad Administration.

Domestic coal users now are making quite a run on Pocahontas. Except for apartment and public building use, bituminous is a drug on the market. Anthracite demand, while gratifying, is not what most dealers believed it would be. Pocahontas, however, does not stay long on the yards. Talk of another 25-cent advance in price is heard. In the last seven weeks 75 cents has been tacked onto the price of forked, while mine-run has continued at $7.20, delivered.

Lake Trade—Tonnage is reported coming out fast, but with the lake carriers getting good dispatch, none is piling upon the docks. A few days ago 4860 cars, or approximately 240,000 net tons, were dumped in one day; this is a high mark for the season to date. A number of large freighters are coming down light from the head of the lakes to take coal back, whereas the freighters usually go up light for iron ore on the down trip. Receipts of anthracite at Duluth in May totaled 129,700 tons, compared with 56,600 tons last May, while bituminous coal received amounted to 1,039,200 tons, as against 777,300 tons in May, 1918.

DETROIT

Consumers of steam coal continue to hold off on orders. Domestic buying slumps with period of hot weather.

Bituminous—Sluggish inacivity is a prominent feature of the local market for bituminous coal, according to jobbers. Consumers of steam coal seem to be slow to realize that those who delay taking advantage of present opportunities for stocking up may encounter obstacles difficult to overcome when they enter the market later.

Receipts of bituminous are unusually light for this season of the year. Jobbers and wholesalers are not encouraging shipments except on the basis of direct-from-the-mines to consumers. One result of this policy is that little free coal on tracks is reported in Detroit, which is a condition in sharp contrast with the period before the war.

Some of the buyers, however, seem to have formed the opinion that the supply of coal awaiting sale is quite large. This impression is created, the jobbers explain, by the fact that several brokers may be working to sell one consignment and may each in turn offer it to the same group of prospective buyers. Little smokeless coal is available. Lump and egg sizes are said to be virtually out of the market, with mine-run selling at $2.75 at the mines for a short ton.

West Virginia mine-run brings from $2.10 to $2.25 and mine-run from Ohio is quoted around $2. Slack is apparently difficult to place with Ohio coal quoted at $1.50 and stock from West Virginia at about $1.85. Hocking lump is held at $2.50, while West Virginia gas or splint lump is quoted at $2.75 and three-quarter lump at about $2.50.

Anthracite—Retailers find that the extreme heat of the last few days has produced a noticable reduction in volume of business coming from household consumers. Anthracite is not reaching the city in large amount, but the principal dealers seem to be getting sufficient stock to supply customers. Efforts of a number of retailers to encourage early buying of anthracite have not brought the volume of orders expected.

Lake Trade—Shipments of coal on the lake routes are holding at a considerable tonnage. Despite the holiday May 30, vessels loaded 966,063 tons in the week ending May 31, of which 39,137 tons was fuel coal. Some vessels are making the downbound trip without cargo to load coal.

COLUMBUS

Improvement is reported in the domestic and lake trade. Steam business is still slow. Fancy domestic grades are strong. Screenings still drag.

The domestic coal trade is now active in central Ohio territory. Buying on the part of retailers is more noticeable as stocking has now started to a certain extent. The fancy grades are moving actively. Pocahontas is selling well and the same is true of West Virginia splints and other smokeless and semi-smokeless grades. Retail stocks are not large in any section, and consequently there is a fairly good buying movement. Prices for Pocahontas continue to advance and the usual figure is $4 at the mines. Consumers are placing orders for their next winter's supply, to be put in in June and July.

Steam business is quiet in most sections. There is a better demand for screenings, which has been the hardest grade to dispose of. Reserve stocks are generally used up and going concerns are now buying in the open market, where rather low prices are offered. Iron and steel concerns are not using so large a tonnage as formerly. Rubber plants are busy but they have some reserve stocks on hand. General manufacturing is gradually expanding and as a result a better steam demand is expected within the next few months.

The lake trade is running along about the same as usual. The movement is slowly increasing but has not reached the proportions of last year. Uncertainty as to price is still holding up some lake contracts. Dock interests are busy filling their docks at the head of the lakes. Vessels are plentiful and chartering is going on fairly well.

Production is not increasing in any of the Ohio fields. This is due to the uncertainty in the steam situation. The Hocking Valley is credited with about 50 per cent. of normal during the past week, and operations in the Pomeroy Bend field were about the same. Eastern Ohio is producing about 55 to 60 per cent. of normal. Other fields are not showing up very well.

CINCINNATI

Market comparatively quiet, but future looks encouraging. Labor troubles expected. Prices hold up. Pocahontas coal scarce.

The market is comparatively quiet. There has been no startling business transacted during the past week, but the outlook is encouraging. A survey of the large dealers shows an improvement, and the near future is expected to see the resumption of the normal trend of business. All the local dealers are dubious about the conditions for this fall, and are endeavoring to educate the consumer of the possibility of a serious shortage. There is also a new problem becoming more and more conspicuous as the weeks pass on. The local dealers are anticipating labor trouble at the mines along about the time when it will do the most harm.

The prices of coal in Cincinnati continue to remain the same as the past few weeks, but the heavy demand in some lines has caused a shortage. Coal from the Pocahontas fields is hard to obtain. There is an acute shortage in this particular grade, and the local dealers claim that it is out of the question to obtain any of this coal. Anthracite also is running short in this vicinity, with no immediate prospects of a normal supply being obtained.

LOUISVILLE

Block demand increasing with stronger market as result of better consumer stocking. Steam grades generally draggy, with spot coal selling at considerably under market. Contract prices fairly firm.

The market as a whole has shown little price change, other than a little stiffening on the part of concerns with fair orders on hand. Domestic coal is strong in price, but steam coal is selling at all kinds of prices. However, industrial consumption is slowly but steadily improving as old stocks run out, but little contract making is being indulged in at this time.

Consumers are beginning to get a little uneasy, and are placing fair orders, with the result that retailers are fairly busy, and are buying nicely. During the past three weeks one retailer has developed business until he is now operating four out of his six trucks, which is a considerable improvement considering the fact that he had been operating but one small truck.

Some of the eastern Kentucky mines are operating full, while others are operating as full as labor conditions will permit. There appears to be a general shortage of labor, resulting in only about 70 per cent. operations for eastern Kentucky.

The Lake movement is now in full swing, and some fair business is coming from byproduct, gas plants and other consumers.

There is also a good deal of coal moving into textile districts of the South, and to Southern ports for export or bunkering.

Jellico, Straight Creek and Blue Gem block coal is selling at higher prices, ranging from $3.25@3.75 per ton. Nut and slack and mine-run from these districts is selling at approximately the same prices as good eastern Kentucky.

The demand is largely for better grades of coal, resulting in low grades going begging. In steam coal the better grades are being quoted at such low prices that operators making low grades have no chance to compete.

BIRMINGHAM

Domestic market shows great strength and little free coal can be found. Prices advance on all grades. Little activity in steam trade, but schedules remain firm and there is no accumulation in the hands of operators.

Inquiry for domestic fuel is exceedingly brisk for this season and it is practically impossible to find any free coal of the higher or even the medium grades. Schedules adopted Apr. 1 providing for an increase of 10c. per ton per month through September have been abandoned except on contract business, and there is a possibility of a runaway market before fall. Quotations on domestic grades are as follows per net ton mines for lump and nut:

Cahaba	$4.50@5.00
Corona	3.50@3.75
Black Creek	4.00@4.50
Carbon Hill	3.25@3.50
Climax and Montevallo	5.00
Big Seam	3.00

The steam trade is still drifting along quietly, but brokers predict a decided change for the better between now and July 1, when a number of large railroad contracts expire and will have to be renewed. It is thought that this will bring about more active buying from commercial consumers generally. Government prices are holding firm and when the market again becomes active sales will be based on that schedule.

Coke

CONNELLSVILLE

Operators have still stiffer views. Sliding scale contracts may be made. Production slightly increased.

Coke operators have become even stiffer in their views as to the value of coke for the second half of the year, owing no doubt to the better reports lately coming from the iron and steel industry, and it now seems improbable that it will be possible for operators and furnacemen to get together on a flat price for second half contracts. In the majority of cases May and June settlements on monthly adjustment contracts were at $4. The furnaces would hardly care to pay as much as that as a flat price over the second half, while on the other hand there is no operator who would accept such a price. They all feel that even if coke is hardly worth $4 now it will be worth much more later in the year. Accordingly some effort is being made to figure out sliding scade contracts for presentation to furnacemen. The difficulty is experienced, however, that present pig iron prices are more or less artificial, representing the remains of wartime control. Taking basic pig iron at $25, valley furnace, which is approximately the quotable market now, there may be a decline

in the next few weeks and afterward a recovery based on demand. If in such circumstances a $25 price were again reached, the coke operators feel that the furnaces would be able to pay a better price for coke than they can now, when pig iron is also quotable at $25. There is some talk of formulating scale contracts whereby $25 pig iron would call for $4.75, with other prices in proportion, with a proviso that until the pig iron market shows strength of its own, a special price, say $4, will be made.

Foundry coke is in better demand and consumers are taking more interest in the better grades. Operators would not sell foundry coke on contract at prices now ruling for spot, particularly as the usual contract runs for a twelvemonth. The spot market remains quotable at $3.85@4 for furnace and at $4.50@5 for foundry, depending on grade, per net ton at ovens.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended May 31 at 111,335 tons, an increase of 3262 tons.

Buffalo—The only indication of change in the dull state of the smelting trade is the chartering of 100,000 tons of iron ore to be brought down at once by boat to Lake Erie ports. This is the first stir of the season, and is small in amount, but it may be the forerunner of much more. Local furnaces are running light and are not buying much ore, which is still quoted at $7.25 to $7.60 for 72-hour Connellsville foundry, $6.60 for 48-hour furnace and $6.10 for off grades.

Middle Western

GENERAL REVIEW

Conditions more hopeful, with plenty of coal moving forward. Price increased on good grades. Labor shortage in fall.

The coal market in the Middle West is at last showing some hopeful signs of a return to a healthy state of activity. The public are buying more freely than heretofore, and each day shows an improvement over its predecessor. A considerable tonnage is moving daily on the open market, and a number of contracts have been closed, although no big contracts. Prices have advanced on prepared sizes on all of the high grade coals mined in these fields, and further advances are predicted for July 1. Franklin County prepared coals are now $2.85 per ton f.o.b. mines, and we understand from a reliable source that some Indiana Fourth Vein lump sold as high as $2.95 f.o.b. mines. The retail trade is affected by these price increases, as there have been few, if any changes in steam coals, although the railroads appear to have prevailed upon certain operators and jobbers to shade their prices.

What little eastern coal is moving into the Middle West is sold, and will continue to be sold, at good prices. This is a decided improvement over conditions a month or so ago, at which time the gas and by-product people received quotations in every mail from West Virginia operators quoting prices on byproduct coal from 50c. to a dollar per ton under the Fuel Administration prices. High grade eastern coals for domestic purposes are in great demand and hard to get. It is generally believed that whatever eastern coal is to move into the west will have to move fairly promptly, as the demand in the east is increasing rapidly.

The labor situation at the Middle-Western mines is continuing without much change. Men are leaving the coal industry for more favorable fields, and the big exodus of the foreign element continues. As conditions are, at present, Illinois and Indiana operators have as many men as are needed, but when the demand for coal comes, as it will come, and soon, it will find a serious shortage of labor at our mines. As no new labor is coming into the field, it is easy to understand why the operators are so anxious to have their favored customers go into the fall and winter months with an adequate storage pile.

CHICAGO

Steam coal demand still inactive, while domestic coal demand is picking up. Little anthracite.

Trade conditions continue without much change, especially in regard to steam coal. The demand for mine run and screenings keeps up, perhaps a little better than in the immediate past, but the movement of steam coal into the Chicago market is still far below normal. It is believed, however, that the steam buyers will come into the market heavily a few weeks from now, when they understand what the coal situation is today.

The domestic situation is changed some. Dealers realize that from now on it will be extremely difficult to obtain eastern coals, such as Pocahontas, etc., in sufficient quantities and they are therefore turning to the nearer fields such as Franklin County and the Indiana Fourth Vein district. Operators in the two districts mentioned above report a great improvement in their Chicago trade, which they believe will continue for some time to come.

We understand that some of the Chicago retailers are having difficulty in obtaining anthracite, and are far behind on their orders. It is predicted by some very closely in touch with the market that what is now true of anthracite will also be true of all high-grade domestic coals sixty or ninety days from now.

MILWAUKEE

All grades of anthracite advanced 10c. per ton, with the exception of buckwheat. Market continues quiet, with selling movement slow.

The coal market at Milwaukee continues quiet. Dealers say deliveries are only fair in volume, due apparently to a disposition on the part of consumers to hesitite at paying present prices. However, an addition of 10c. per ton on all grades of anthracite except buckwheat, which became operative June 1, may tend to dispel this feeling. Dealers have been looking for an advance in bituminous coal also, as Western operators are charging from 75c. to $1 more at the mines; but thus far the soft-coal schedule remains undisturbed.

Receipts by lake thus far aggregate 177,980 tons of anthracite and 725,672 tons of soft coal, a gain of 76,519 and 271,131 tons respectively over the receipts during the same period last year.

The City of Milwaukee will soon be in the market for about 60,000 tons of coal, mainly bituminous. During the war the city was supplied through a pooling arrangement between city dealers, but competitive bids will now be sought.

Prices of anthracite are now as follows: Chestnut, $12.40; stove, $12.30; egg, $12.10; pea, $10.90; buckwheat, $9.75.

ST. LOUIS

Business generally quiet with increase in inquiries from country for threshing coal. A slight increase in local call for domestic coal, while steam continues to lag. Condition shows little improvement.

The local situation shows some improvement, but not to any marked extent. Orders for storage coal have been more numerous in the last week, and there will no doubt be a general movement from this time on that will not reach its highest point until perhaps July or August so far as storage fuel is concerned for domestic purposes. The greater portion of that moving now seems to be anthracite. There is an increasing call for smokeless coal.

On the Illinois coals the Carterville grades are leading. The call for Arkansas coal is light and there is nothing to indicate that any of this fuel will move in here in tonnage worth considering.

Steam business continues to have a depressing effect on the market. The large steel plants in East St. Louis and Granite City are running short time, and some of them have suspended altogether, putting a large tonnage of steam coal on the market. This has kept screenings and small nut down. The steam business throughout the country does not seem to be anywhere near normal either.

Conditions in the Standard field show no improvement. As a matter of fact, they continue to grow worse. The steam-coal problem is a serious one, and in the face of a poor steam market the prices on domestic sizes seem to go down instead of up, on account of the over-production. Nearly every mine in the field is selling coal at about the cost of production and below, in order to keep their organization together, anticipating a big demand in the near future. Competent observers contend there will be no extraordinary demand for Standard coal until the middle of the winter, and then only if the weather is severe and an unusual car shortage occurs. The mines continue to work two and three days a week. The railroad tonnage has increased some this week.

In the Mt. Olive field the railroad tonnage does not seem to be large, but there is a fairly good movement of both steam and domestic to Chicago and the Northwest. A considerable tonnage of this coal, especially the washed sizes, was recently contracted for at Kansas City, and some is moving to Omaha. The conditions in the Mt. Olive field are satisfactory, everything considered.

In the Carterville field of Williamson and Franklin County, Illinois, and the Duquoin field, the one great problem now is the steam sizes. At Benton, Ill., it is estimated there will be 100,000 tons of coal piled up at the mines, and at other mines in the field screenings and sizes from No. 2 to No. 4 have been piled up. This is accounted for by the fact that industrial conditions in the Middle West are bad, and there is no call for steam coal that usually at this season of the year was greatest in demand.

The demand for domestic sizes shows a steady improvement, especially to the Northwest. Locally there is a small tonnage moving in, but this is not a factor in the situation. Cars are plentiful and the movement is good, and a general way conditions show improvement, except on steam coal. Some mines still continue idle and all are working short time. The railroad tonnage from this field shows up fairly well and is the only important factor in keeping the mines going at this time.

COAL AGE

Volume 15 New York, June 19, 1919 Number 25

That These Men Shall Not Die in Vain

By R. Dawson Hall

THE terrible loss of life in the Baltimore Tunnel must not be allowed to be forgotten till all the important lessons that it has taught have been driven home. Admittedly the law in the anthracite region, as far as the transportation of explosives is concerned, is wholly inadequate. The coal company that operated the tunnel tried to make up for that defect, but the men, finding the cure involved them in much trying labor, demurred. As a result there was a compromise, and the company devised a plan with the union which would have prevented the accident in question had it been adhered to.

One of the Cars After the Explosion, Showing Powder Kegs and Dinner Pails.

The powder was always to be hauled in the rear car of a long trip, and an empty car was to separate it from the cars conveying the men. The union was to be responsible for the execution of the order. Unfortunately the grievance committee, which represented the union at the mine, allowed the men to violate the agreement, and the accident happened.

Men like to keep their kegs of powder in their own possession. They do not like to deposit them in a car trailing some distance behind, for there is always a risk of theft. On the other hand, they can only with difficulty be induced to carry them two or three miles to the working face. When they do that they must lug their tools and dinner pails also, for they will not trust their equipment on the trip without being there to watch it.

Though, in the Baltimore Tunnel disaster, the powder in the rear car did not burn or explode, yet there is always just that risk where powder is hauled by an electric locomotive, even when it is placed in the last car of a long trip, unless the powder is carried in a properly insulated box. This for other reasons should be lidded and locked, and in care of an attendant with an electric light in his cap. It may not be necessary to follow the Illinois law and place the explosive near the working places in the interval between shotfiring and the entrance of the day shift, while the current is turned off on the roadways along which the explosives are hauled, but it is necessary that the powder be hauled in a dry and nonconducting box to which sparks and lights cannot have access.

The Illinois plan has some advantages, but there will be danger nevertheless if powder is stored in the mine and distributed in the presence of a lot of excited miners, with lights on their caps, who are anxious to get to work; and more dangerous yet, if there is no one on hand to do the distributing.

Every state should scan its mine laws with care to discover defects that may make a recurrence of a disaster like that at the Baltimore Tunnel possible. In few bituminous mines could it have occurred without stirring up the coal dust and causing a violent explosion.

Sealing Up Old or Abandoned Workings in Gaseous Mines*

The Good or Bad Effects of Sealing Off Worked-out Portions of a Mine Have Never Been Definitely Agreed Upon. The Proper Ventilation of Such Places Is Difficult. A Method of Procedure That Is Neither Difficult nor Dangerous Is Outlined

By C. Thompson
Director, Department of Mines and Minerals, Illinois

THE advantage of sealing up old workings in fiery or gaseous mines is a subject that has received but scant attention among mining men. It is true, however, that every once in a while this matter is raised without any definite conclusion being arrived at or any system being suggested. I think the reason for this is obvious and arises from the fact that it has been dealt with as a matter of personal opinion and in consequence was a subject that could not be argued to a logical conclusion.

Neither have the tremendous possibilities and dangers arising from the extensive working of deep beds generating large quantities of methane presented themselves to men's minds, inasmuch as they had until quite recently only mined in the shallow measures, where little or no gas of this kind was generated. In some instances what deep mines were in operation had not been extensively developed, and therefore the need for intelligent precautions had not become obvious. Today conditions are different, and we stand face to face with an important and serious situation; consequently, it becomes our duty as thinking individuals to put aside all matters of personal opinion and deal with this question as becomes men who realize that the subject is one fraught with the greatest possibilities in regard to the safety of human life and limb, the protection of property and the successful recovery of a valuable mineral for the benefit of the nation.

IT WOULD seem that the chief arguments of those who are opposed to the system of sealing off old or abandoned works may be summed up in one sentence: Is it not better to ventilate old works, and keep the gas out, than to seal them up and allow the gas to accumulate behind the seals? To this question the amateur would probably answer, Yes.

But the experienced and observing mining man would likely say, "Yes, if this can be done." It must be realized that this is not fully accomplished, and as the works become more extensive the difficulties increase, and as they grow still more extended, it will ultimately become a physical impossibility to seal them effectively.

To illustrate: Suppose you have an extensive area to work, say, the cross-entries have a mile and a half to go from the main entry to the boundary line. This would give 7920 ft.; and if the panels were 420 ft. between each pair, this would give a 200-ft. room with a 20-ft. barrier between panels. This would mean 15 pairs of panels on each side of the cross-entry. Suppose that it was intended to have 14 rooms on each panel; the panel entries are 10 ft. wide and the coal 8 ft. high, the rooms 25 ft. wide on 50-ft. centers and 200 ft. deep. Then, when this pair of panels was finished, there would be a space of over 1¼ million cubic feet. This, if not properly ventilated, would fill up with deleterious gases, chief among which would be methane.

Now, consider what the position will be when there are, say, ten pairs of panels finished. Take those panels on the intake aircourse side. It would be necessary to install some sort of regulating door across the aircourse to force the air into these panels, or they would not be ventilated. This would have to be done with every pair of panels; and, provided there was available a reserve of ventilating power to make this possible, do you believe that any intelligent and experienced man would or could take the responsibility of asserting that this air, affected as it would be by the transpiration of the various occluded gases, would be fit to sustain health and life? Certainly not.

AGAIN, it must not be forgotten that it would be necessary to have some means of forcing air into the panels on the return side. This would mean an overcast or air crossing over the haulage road from the intake air-course, or a door on the haulage road. Such a crossing would have to be made for each pair of panels. When all this is done, what condition do you suppose the air would be in on the inby side of this, where the miners all have to work? It would certainly not be an atmosphere that contained a reasonable amount of pure oxygen.

Yet, again, it must be remembered that the stoppings between the entries would probably decay in a comparatively short period; certainly some of them in less time than that represented by the life of such a district. When this occurs all the area on the inside of that point would be unventilated and would fill up with gas. A sudden fall then occurring might force out thousands of cubic feet of methane. This would be carried by the air current to the first open light or even the trolley wire with the motor coming along. And then, well, may God in His mercy help those that were there!

The question quite naturally arises: What method should be adopted in sealing off panels? I am of the opinion that there is only one distinct method that can be adopted with success and a fair guarantee of safety, and that is, when the first pair of panels in a district is finished, leave them open and ventilate them until the second pair is finished and the third pair started; then seal up the first pair. When the third pair is finished, seal up the second pair, and so on, always taking care that the pair of panels on the inside of the pair

*Paper entitled "Advantage or Disadvantage of Sealing Up Old or Abandoned Workings in Mines Generating Methane," presented before the annual meeting of the Illinois Mining Institute, May 23, 1919.

next to be sealed is finished. It will readily be seen that this method offers the best guarantee of safety against inadvertently holing into a confined body of gas pent up behind the seals.

On the other hand, if the first pair were sealed up as soon as finished, there would be a possibility of holing some room from the second pair into the first pair, with serious consequences.

The question has been asked, What kind of gas would exist behind the seals and what condition might it be expected to be in? To answer this it is necessary to call attention to the condition in which the gas exists *in situ*. One scientist has asserted that it must exist *in situ* in the form of a perfect gas. Such a condition, however, is difficult to comprehend as it suggests the existence of something that is a tangible substance yet occupies no space.

However, we do know something about occluded gases. A gas is occluded—that is "hidden"—when it exists in the pores of a solid substance. A familiar example of the occlusion of gases is found in the coal beds, where gases often exist in large quantities and are a source of danger in mining.

The conditions that have held these gases in the coal and adjoining strata till set free by the penetration of mine workings are largely a close coal and an impervious roof and floor. The gases most commonly occluded in coal beds are methane, nitrogen, carbon dioxide, carbon monoxide and some other hydrocarbons. The relative percentages vary largely in different localities and even to a considerable extent in freshly mined coals.

THE pressure of occluded gases has been shown by a number of experiments in England, France and Belgium to reach as high as 250 lb. to the square inch. Whatever degree of exactness these experiments may have they serve to show at least the enormous pressure under which occluded gases may be projected from a newly exposed face of coal.

The term "transpiration" as here used relates to the more or less steady outflow of occluded gases from the pores of the coal. It has been found by experiment that the velocity of transpiration, like the velocity of diffusion, is different for different gases subjected to the same pressure. However, it has been demonstrated that the velocity of transpiration, unlike that of diffusion, is independent of the density of the gas.

The rate of transpiration of the different gases occluded in the coal has an important effect in determining the character of the gaseous mixtures issuing from the seam and consequently the gaseous condition of the mine.

The more rapid transpiration of the hydrocarbon gases such as methane or firedamp and ethylene tends to increase the percentage of these gases in the mine air, while the percentage of carbon dioxide and nitrogen which are always present to some extent in the coal is decreased owing to the same cause. In some coals methane has been shown to form 93 per cent. of the occluded gases. In others nitrogen and carbon dioxide have formed 54 per cent. Oxygen rarely exceeds 4 or 5 per cent.

Once we clearly comprehend how the transpiration of gases proceeds under ordinary conditions, we are better able to understand what would be likely to take place behind the seals. It is true that some of the opponents of this method have suggested that the gases behind the seals might reach a high pressure and possibly cause a sudden outburst of gas. This, however, is a remote possibility, if it is possible at all.

It must be remembered that the pressure of the occluded gases has already been much reduced during the working process, and the increased pressure of those gases still pent up behind the seals would further retard the transpiration of those yet occluded, until it is probable that transpiration would cease.

Again, we must remember that the gases behind the seals should be much less dangerous than those accumulating in old workings where the mouths of the entries are open to the atmosphere, because where the entries are thus open the gases diffuse with the oxygen of the atmosphere, while those behind the seals have practically no oxygen but will be mixed with some of the other occluded gases.

To my mind all the evidence and possibilities are in favor of the method of sealing off old or abandoned workings. Such a procedure would insure a more healthful atmosphere for miners to work in and increase their efficiency; it would afford an almost incalculable safeguard to property and reduce the danger to human life and limb to an extent that would reflect credit to the mining industry.

In conclusion, I wish to state that the members of the Department of Mines and Minerals of Illinois, which includes the inspectors, has no desire or intention of being arbitrary, neither do they wish to dictate their opinions to others. They are anxious, however, to impart to others their ideas and knowledge of known natural laws which experience has taught them, with the hope that all may coöperate and help to reduce the risks of a hazardous occupation. We may all thus do our duty to our fellowman, to the state and to our country.

Health in Its Relation to Industry

Large organizations are beginning to realize what every employer of labor must sooner or later learn: that the success of an industry lies in the health of its workers. Given an incentive, every workingman will labor to his maximum endeavors. But your worker, first of all, must be sound physically and morally in order to be of value as an industrial unit. Just what has been accomplished in the way of health insurance and disease preventive measures, and its effect on the industries in which the plans are being operated successfully, is admirably set forth in an article headed "Health and Industry," by Floyd W. Parsons, in the June 7 issue of the *Saturday Evening Post*. It would repay every coal-mine executive to read this article. In passing, it may be mentioned that Mr. Parsons, who as the former editor of *Coal Age* needs no introduction to the coal-mining world, will shortly start his Science and Industry Department in the *Saturday Evening Post* as a regular feature of that periodical, the editorial staff of which he is now a member.

MOST OF the coals received by the Bureau of Mines came in barrel-lot shipments for test in small low pressure boilers; therefore, domestic rather than steam sizes predominated. To determine the weight per cubic foot, the coal was shoveled loosely into a box measuring 2 x 2 x 2 ft. inside and the coal was leveled off with a straight-edge.

Interesting Summer Sessions of Three Coal-Mining Institutes

By R. Dawson Hall
Managing Editor, *Coal Age*

A description of the summer sessions of three lively state institutes, one held on the Mississippi River between St. Louis, Ill., and Kenova, Mo., another at Huntington, W. Va., and a third at Lexington, Ky.

Institute De Luxe in Illinois

TO S. T. JENKINS and his committee of arrangements in the Illinois Mining Institute must be credited the extremely favorable circumstances under which the institute met. A boat was chartered, the "Golden Eagle," and, for two days and a half the institute traveled the waters of the Mississippi from St. Louis, Mo., to Quincy, Ill., thence to Keokuk, Mo., and back to St. Louis. Many of the participants enjoyed the affair so well that they stayed up all night so as not to shorten the pleasure unnecessarily by anything so prosaic as sleep.

The boat left St. Louis on Thursday, May 22, with 96 members aboard, and on its cruise to Quincy read and discussed two papers, one on "Power Transmission Methods in and Around Coal Mines," by S. W. Farnham, and the other on "What Constitutes a Proper and Lawful Examination of a Mine by a Mine Examiner," Steve Gosnell, of Holidayboro, Ill., being the exponent. The number in attendance constituted a full capacity load for the good ship "Golden Eagle," when captain, pilots, bandsmen, cooks and waiters were taken into account.

The boat turned her paddles so industriously that despite the unusually high river she bade fair to get to Quincy ahead of time. So the boat was stopped for an hour and a half and one of the papers read in the silence resulting, for it must be remembered that a river boat does not fail to give evidence of its progress in sundry creakings and paddle noises such as make speechmaking a trifle labored and hearing a little difficult.

The boat arrived at Quincy at 10 a.m., and the Quincy Chamber of Commerce was on hand to take the members over the pretty town and through a seemingly endless chain of parks, beginning with the 275-acre park surrounding the State Soldiers' and Sailors' Home, where 2000 veterans and their wives are pleasantly passing their declining years. Quincy boasts of the following parks: Parker Heights, Gardner Park, Sunset Hill, Riverview, Edgewater, Indian Mounds Park and South Park. There are so many trees that from the heights the city looks more like a wood than a town of 36,000 inhabitants.

After a short session at the Chamber of Commerce, where the members were welcomed as guests of the city of Quincy, they returned to the boat, which slipped cable and stood for Keokuk, Mo. In the afternoon a session was held with the paper of Joseph C. Thompson as the subject of discussion. This contribution appears on page 1110 of this issue. It is entitled "Should the Abandoned Workings of a Gassy Mine Be Sealed or Ventilated?" There was no adverse opinion, everyone agreeing that Illinois mines at least should always seal off their abandoned workings. The dangers of mine fires in the old gobs make this practice more necessary in Illinois than elsewhere.

Another condition in Illinois which makes sealing more necessary than elsewhere is the practice of leaving pillars of such a size that they will sustain the roof over old workings. As a result, large areas remain open in such a degree that they can give off gas. The surface property is worth more than the coal, and the coal companies in general do not own the surface. When that surface is cracked or waters removed (even where the waters have been an annoyance and not an assistance) the juries of Illinois have habitually given awards to landowners far in excess of the value of the land. Consequently coal operators have had to leave much mineral to sustain the surface. That being so, the areas are not self-sealing in any way, but nevertheless the condition of the abandoned workings soon becomes such that these workings cannot be traveled and adequately ventilated. Sealing is the only alternative and it should be done soon—before fire invades the pillars.

It was pointed out that a large part of the gas where it did not come from the roof was emitted not from the ribs of a mine but from the coal face and from the coal broken by cutting, blasting and loading. When the coal was not disturbed it ceased to give out any large volume of gas. Any sealed area, it was said, soon had an excess of carbon dioxide and a depletion of oxygen. When properly sealed it did not gain pressure as time passed; in fact, as Mr. Needham pointed out, the pressure was as often negative as positive. The ribs actually absorb oxygen and probably turn it to carbon dioxide and water or else occlude the oxygen in their porous structure.

Mr. Needham remarked that in western mines where there were heavy bumps he had sealed off many levels and left observation holes in the stoppings which he could open and close at will. On removing the plugs the mine examiner found that, at times, the holes inspired air and at other times expired the atmosphere of the gob. He added that while a cap could be obtained near the mouth of an expiring hole, the gas was not of such a quantity that a cap could be obtained in the entry near the stopping. Moreover, he added, falls of rock did not seem to increase the flow of air from the holes even when these falls were severe.

Drilling abandoned areas from the surface was also considered by some speakers. Some have put a mercury seal on such openings so that they would discharge the excess air, if the pressure became excessive, and a seal of this kind was suggested for use with the holes provided in stoppings, but no one seemed to think such mercury seals necessary in view of the small excess of pressure in a sealed area above the normal pressure of the atmosphere. One member suggested that a more profitable subject for discussion was where stoppings should be placed in the sealed area and of what materials they should consist.

The boat reached Keokuk in schedule time and, passing the city, went up to the dock and landed its passengers for a view of the great power house and dam of the Mississippi River Power Co. The dam is 4278 ft. long, not including in this the east abutment of 290 ft. and the west abutment of 81 ft. Altogether it measures 4649 ft., or 88-hundredths of a mile. Its width is

Now that hostilities are ended, the institutes revive their activities and prove more active than ever before. The Illinois men met on the Mississippi River, in a well-equipped river steamer, and the Kentucky men revived most successfully their first-aid contests. The West Virginia managers discussed with ardor the problem as to the possibilities of coal conservation in the Kanawha and New River fields.

29 ft. at the top and 42 ft. at the bottom. Its height is 53 ft. There are 119 arched spans of 30 ft. with 6-ft. piers between.

The power house is almost exactly a third of a mile long (the actual figure is 1718 ft. instead of 1760 ft., which constitutes a third part of one mile). Its width is 132 ft. 10 in. and total height 177 ft. 6 in. There are 15 power units, each consisting of one 10,000-hp. turbine with an overload capacity of 13,500 hp., an hydraulic chamber having four intakes converging on a scroll chamber 39 ft. in diameter and an electric generator of a capacity of 7500 kw., generating 25-cycle, three-phase 11,000-volt alternating current, which is stepped up to 110,000 volts for transmission.

After the party had visited the power house it was taken by the automobiles of Keokuk citizens through the town and surrounding country, including the grounds of E. I. Dupont de Nemours & Co. Returning to the landing the regular addresses of welcome and of thanks were given in good measure. Having had a chance to sample the hospitality and to visit the town, the guests were well equipped to express their appreciation, so if the welcome was belated, the response was in good season.

In the morning all hands turned to the disposal of the remainder of the program. The first paper read was one by T. H. Tracy entitled "Know Your Battery Better." It has appeared already on page 1036 of the issue of June 5. The discussion was quite animated.

The following statement in the paper was traversed quite severely, but without budging the author from his position: "Operating instructors for storage batteries say little about discharging. As a matter of fact, a battery may, without injury to the plates, be discharged at any rate of current that it will deliver. There has been a widespread opinion that high rates of discharge are detrimental to the life of a battery. I can find no justification for this opinion with modern storage batteries."

It was said that too rapid a discharge was apt to cause undue heating and that discharge rates should accordingly be kept down, but the author, while admitting this, declared that it was unlikely, under any condition of operation, that there would be any such excessive temperature. There is a limit to the energy in a storage battery. If a battery is used in such a manner as to draw so rapidly on its capacity as to unduly heat it, it will lose energy so fast that it will be no longer capable of an excessive output. Thus the battery will protect itself from overheating. Its own limited energy will prevent excessive temperatures.

The character of water to use in batteries was also discussed. One speaker said that practically the only safe water to use was that which had been distilled. The water from the Great Lakes would serve the purpose, but in 95 per cent. of the places one could not feel safe without an analysis.

A representative of the Edison Company remarked that many of the statements in the paper about lead batteries applied quite closely to the Edison batteries. The voltage of the Edison cell was somewhat lower, namely 1.2 volts per cell. In consequence it was necessary to have more cells. The change in gravity of the electrolyte was practically nil. There was some change in specific gravity, this, however, being due not to discharging and charging but to evaporation.

The Edison cell is not affected adversely by a total discharge, this being in marked contrast to the lead battery which should not be allowed to part with more than a certain amount of its stored energy. Lights should not be permitted where Edison batteries are charged, for these batteries liberate explosive gas just as does the lead battery. The Edison people recommend that, in charging, the attendant keep the temperature below 110 deg. F., but where the temperature of the cells on commencing the charge is already high, this is sometimes difficult and all that can be asked is that care be taken not to exceed 110 deg. by any unnecessary margin.

For charging the storage batteries it was stated that the charging panel was the cheaper to provide, but a motor generator set is more economical in the long run though more expensive in first cost. With a simple charging panel the voltage is uncertain, and the results are not of the best.

In place of Martin Bolt, H. M. Wilson, director of the Department of Inspection and Safety of the Associated Companies, made a short address on industrial democracy. It was decided by the meeting to hold the next session of the Illinois Mining Institute in Springfield, Ill., on the third Saturday in November (Nov. 15). The officers of the institute were continued in office till that date. Many encomiums were tendered the committee of arrangements and the citizens of Quincy and Keokuk.

The secretary announced that contributions aggregating $3005 had been received from coal and supply companies. Other donations are expected. As the mining institute does not publish proceedings it does not have much need for money, and the funds on hand are now quite large. The expenses of the institute in the river excursion were largely, if not entirely, met by the fares collected from the participants. The fund now provided will enable the institute to arrange in the future for the perpetuation of their proceedings.

A superintendent should worry less about what he does not have and make more of what he does have in the way of available human equipment. In any good country good citizens are more numerous than bad. Every superintendent can bank on the support and fair dealing of most of his men if he can only avoid that common habit of seeing only the grouches of the grouchy while overlooking the smiles of the good-natured, thus embittering those who are most ready to stand by him.

West Virginia Coal Mining Institute

THE twentieth semi-annual meeting of the West Virginia Coal Mining Institute was held on June 3 and 4 in the Frederick Hotel, Huntington, W. Va., the genial Josiah Keely being in the chair. I. J. Harshbarger, the mayor of the city, welcomed the members present, and then the institute, in the person of its president and vice presidents, began to look over the session in the well-recognized disparaging way which institutes affect, despite the fact that the number present was larger than usual. When will institutes cease looking at themselves in the glass like a vain but freckled girl of sweet sixteen? Too much time is devoted to this uninteresting job. Let the president and secretary do their work and leave the rest to fortune. So much introspection wastes time and spoils the pleasure and value of the meeting.

In the absence of Floyd W. Parsons, R. Dawson Hall led the discussion on the Labor Situation with a few words of encouragement regarding the signs of the times, which are not nearly as menacing as some seem disposed to think. Only about 10 per cent. of any body of men in any industry are unreasonable. There is a reliable 90 per cent. of really good fellows, who, if they aren't already, will eventually make excellent American citizens. Vote they will or vote they do, and if we trust them to vote at the polls to direct everybody's affairs as well as their own, surely we can trust them when directing their own affairs.

True the 10 per cent. of evildoers are to be noted on every hand hard at work making trouble. We see them a hundred times as often as we see the reasonable men who do their work, put their dinner pails under the arms and go home quietly to their families. Like a sore thumb, the eye lights on the trouble maker every moment. We cannot see the 90 per cent., for they are

farther from the eye. As the physicist would say, "They subtend a smaller angle of vision." But the 90 per cent. are there, nevertheless, partly led by and partly resisting the aforesaid 10 per cent.

The operator can address himself to the 90 per cent. whereas the agitator has only 10 per cent. as his natural audience, and with a little diplomacy the operator, having all the advantage, should be able to get what he wants, if what he wants is right. His start is good if he does not anger or displease the members of the larger group, who will stand for fair play and sober measures, when real explanations are given to them as to what constitutes fair play and what measures are within reason.

The operator should, like a "movie" camera man, patiently turn aside the lens when the troublesome men place themselves before the rest for a "close up." He should take a view of the 90 per cent. behind. In none of his plans should he forget them. He should be patient with them that they may have patience with him. With the numbers on the operator's side he should never despair.

The logic of unchanged wages and hours was then presented by the speaker; and the power of a knowledge of facts to produce reasonable action by unions was shown by a reference to the known conservatism of men long engaged in union labors. They soon begin to see the facts and to become less radical. The man with the pick is apt to realize the problem inadequately and to think that the largest wage he can secure is fair to other workingmen and helpful to labor as a whole.

However, a little discussion will convince him that he must not demand of the workers in other industries an undue rate of pay, merely because coöperative bargaining, made powerful by the right to strike and the power to boycott, can secure him what he would like to obtain. The business of mankind is swapping services, and the labor of the miner is not worth twice as much as the labor of the bricklayer or carpenter who works an equal or longer time.

James A. Hall of the *Black Diamond* and Wightman D. Roberts of the *West Virginia Mining News* did not speak as scheduled, the first not being present and the second being present, but not in good health.

In the afternoon, in the absence of J. L. Thomas, president of the Carbon Fuel Co., a paper was read by his representative on the question, "Is There an Overproduction of Coal in America?" His answer to that question was that there is and always has been such an overproduction despite the increased demand. Coal output has always had to wait on car service. The coal industry has been unfailingly adequate when it had railroad cars enough to supply the demand for coal. According to the speaker, this was the case all through the war.

However, it must be confessed, there was a short period during which the railroads did outstrip the mines, but the mining plants at that time were producing more than the country could use because they were trying to build up immense stocks, all coal piles being completely exhausted during the previous period when coal cars were so infrequently delivered that the mines worked only a small part of the week.

The problem of production is a transportation problem and, as was stated in the discussion, perhaps the best solution would be one in which power would be transported electrically, the coal being burned at the mines to drive electrical machinery.

Mr. Keely made the statement that the failure of the railroads to supply cars was the only redeeming feature in the coal business, that only the high prices then obtainable made the industry one which could show a margin, for the competition when the railroads afforded enough cars to fill the demand was so great that the business was in such periods conducted at a loss. This is true, but there is no denying the fact that the car shortage stimulates business unduly and makes many investors enter the industry who should stay out, glutting the market with coal whenever a proper car supply again becomes obtainable.

> Runaway coal markets may bring a fleeting profit to the coal operator but the modern business man would rather have a steady and reasonable profit which would save him from aspersions as a profiteer. For these reasons he is looking around for a flywheel warranted to keep the industry running at an even number of revolutions, month in and month out. He knows that high prices only flood the coal region with unneeded producing plants and make mining unprofitable 90 per cent. of the time.

No industry can be equitably and satisfactorily conducted that requires runaway prices at some times to overcome down-at-the-heel prices at others. The coal industry should be conducted on the basis of steady and reasonable returns at all times without plethora or famine. If only it could be arranged that it would pay the consumer to buy the year over, keeping the men engaged in the industry busy all the time, we would have a business which would meet the approbation of the public. Every effort should be directed to that end. A freight differential, and even a wage differential, in the summer would have just that effect.

It would make it customary for the buyer who had or could secure storage facilities to buy coal then. It is the duty of the buyer to lay in for the winter. It is not right for him to memorialize the public to compel fair prices and large output during the winter months so that he can crowd production into a few hectic weeks when all the rest of the year mine workers and equipment lie idle. Operators have a right to make hay when the sun shines if the sun shines only once in ten years.

It is to the best interest of the buying public as a whole to spread its purchases, but without differentials self-interest is so strong that each individual buyer will not buy unless he has a reasonable assurance that winter will bring a higher rate for coal. All parties—public, railroads, operators and mine workers—should combine to keep the coal industry in steady operation at a reasonable rate of profit. But unfortunately, the coal industry is now prince and now pauper. A better way would be a condition with less of a gambling chance.

Short Time Due to Meager Demand

As it is now, a lack of need for coal is accompanied by an even greater shortage of demand, for when the coal requirement falls the demand falls below even the small need and the mines work only a fraction of the time. The certainty of a bigger price in the winter would regulate the industry, as has been proved by the experience in the anthracite region. The differentials obtaining in that branch of the coal trade, bitterly opposed as they have been by the uninstructed public, have been approved by Government officials, and anything tending to establish such a 100 per cent. of production from month to month would be a blessing to every one, whether public, employers or employees. There is a terrible waste in the ebb and flow of the coal industry.

Waiting for work and then overworking, the business of producing coal has become a gamble. A slightly lower rate in the summer, when coal production is least difficult and when railroading is conducted under favorable circumstances, would put the coal business on a wholesome basis free of apparent profiteering, recriminations between operator and employee, and quarrels between the public and the industry.

The discussion on the recovery of coal developed the usual doubts as to the feasibility of mining all the coal in, at least, certain of the seams of West Virginia and a question as to the possibility of mining beds above those worked if the lower beds are mined completely. As usual the Pocahontas and the Fairmont men believed an 85 per cent. recovery of almost any bed was possible and there were many who felt that the damage to beds above had been over-rated as a general proposi-

tion, but the representatives from the Kanawha river field were unconvinced as to both the former propositions. These matters must always be approached with some diffidence till someone has gone into the field in question and shown how, and how easily, the trick can be turned by a proper observance of the correct rules of the game.

C. R. Jones, dean of the West Virginia University, followed with an address on "Labor-Saving Devices," saying truly that labor had every reason to support their introduction and extension. Before such devices were put into operation the working man made the barest of subsistence. Today he has more leisure and a much more generous living. The difference is due entirely to the labor-saving devices that have been installed.

In the discussion which followed much was said as to the work of the coal-loading shovel at the mine face. Prof. E. N. Zern said that the shovel *per se* was without question an unqualified success. The difficulty was to get the cars to the shovel. Mr. Bowman of the American Mine Door Co. stated that at the salt mines in Retsof, N. Y., Cadwallader Evans was loading 450 tons a day with three men and a driver.

The roof of this mine is of great strength, and rooms of ballroom size can be extracted without the use of any timbering and as a consequence it is possible to shoot, it is said, enough salt in one room to keep a single shovel busy for a full day. The problem to be solved is one of supplying the shovel with cars and not of shoveling.

The manufacturer has supplied the operator with the tools for his purpose, and it is up to the industry to provide the means by which the shovel can be kept operating steadily at capacity. In short, the shovel being provided, it remains for the industry to discover some means of building the mine around the shovel so that the tonnage may be safely and expeditiously loaded by it. This is the problem. The manufacturer has not failed, it is the mine manager.

Some Remarks on the Future

On Wednesday, Prof. E. N. Zern addressed the institute on "The Coal Supply of the Future." He said:

"While felicitating ourselves on having trillions of tons of coal in this country, we have failed to take into account that the greatest bulk of coal is of low rank, and that the highest rank of coal has been relatively scarce. Production in all these years has been coming not from areas of greatest quantity, but from the areas which contain the best coal.

"The situation into which we are rapidly drifting is illustrated by the story of a large coal user in an eastern city, who some years ago in his bewilderment called a salesman and inquired why he was being given inferior steam coal, whereas in the past he had always used Moshannon coal. 'The explanation is simple,' said the salesman, 'there is not enough Moshannon coal to go around.'

"The statement that our coal resources are rapidly approaching exhaustion is every bit as misleading as to say that 99 per cent. of our coal deposits still remain untouched and there need be no concern for the future. Both statements are in need of qualification.

"Many of the various mining localities, producing high-grade coal from our most valuable and accessible seams, are reaching, or have already passed, the peak of production and must steadily recede in output.

"This is especially true of coal deposits tributary to the industrial region of the Middle Atlantic.

"After a century of marked advantage in mining, we are passing through the twilight zone and must soon emerge from this to encounter more difficult mining in seams of widely varying quality.

"Not only will coal mines of the future be attended with more difficulties and hazards, but, furthermore, it will be more costly. The initial investment will needs be greater. Until recently, comparatively few shafts have been sunk, and most of these of shallow depth A time is rapidly approaching when mining by shaft will be the rule, instead of the exception.

A paper by W. T. Heatherman on "The Most Common Violations of the Mining Law" and by J. W. Bischoff on "Preparation of Coal" concluded the meeting. Mr. Bischoff quite wisely said that the reputation of a coal was quite largely determined by the presence of pieces of slate and bone which if taken count of by analysis would not be considered of any great importance. One per cent. of visible ash would lead to the rejection of a whole carload of coal where 5 per cent. of excess intrinsic ash would be overlooked by the consumer.

After all, the loose slate and bone are the operator's and miner's fault, and not their misfortune, and it is much easier to overlook a misfortunate inability to deliver good coal than to pass over an apparently deliberate indifference as to quality. As the motto goes, "What can't be cured must be endured," but slatey coal can be cured where high-ash coal cannot.

The miner and operator regard coal as being worth what they get for it. They do not see why they should spend more time and money eliminating impurities than the purchaser pays for them. But they should never forget that the purchaser has a right to entertain a different view. The coal he gets is coal plus railroad transportation, plus delivery from the yard, plus the fireman's wage, plus the ash remover's charge (unless the last item can be saved by the value of the ashes for concrete or filling or the ash can be dumped without expense). To him also ash causes actual coal waste by imperfect burning. He does not regard the ash impurity as indifferently as the operator. It reduces his boiler capacity and makes it hard to run his machinery. The operator must sense his point of view or give way to someone who will.

Many were the necessary and advantageous assumptions of authority during the period of the war. Among these was the act of Josiah Keely and Karl F. Schoew, president and secretary, respectively, of the West Virginia Coal Mining Institute, in extending the period of their service beyond the period contemplated in the by-laws of the organization. No meeting having been called during the war, they could not provide for an expression of the mind of the members and carried on most manfully and prudently without any mandate. The institute before it closed its session voted to extend their period of office till the winter session, when an election will be held.

Kentucky Mining Institute

A GOOD attendance was secured at the Kentucky Mining Institute which met in the Phoenix Hotel, Lexington, Ky., on June 6 and 7. The members saved themselves a lot of time by not looking themselves over and wondering why they were not assembled in larger numbers, which is the regular way in which mining institutes waste time and discourage membership.

Professor Freeman was introduced by the president, K. U. McGuire, and he made a statement regarding a project of the universities and institutions of learning generally to erect memorial buildings in honor of those who fought and who died in the war. The University of Kentucky proposes to erect a Students' Activities Building in Lexington on Limestone and Winslow Streets, facing the latter, to cost $300,000. From 3 to 290 persons in each of the 120 counties in Kentucky died in the war, a total of 2736 Kentuckians, counting both the male and female members of the service. The institute, before it adjourned, voted an indorsement of the commemorative movement.

The president then read his annual address. Mr. McGuire is not one of those who are disposed to resist progress, and that his remarks well proved. "The coal operator," he said, "who so desires, will find it futile to oppose the demands of laboring men and women for constantly improving conditions of work and living. He should rather engage in a generous rivalry with other operators and devise and imitate social betterments. By such improvements he can do much to forestall Bolshevism in America."

Mr. McGuire would have mines safer and healthier places to work in. "The interior of a coal mine cannot be made a garden of roses, but fewer men and more machines inside the mine and more men outside in related industries is the desirable situation."

"These related industries, including iron and steel and the distillation of byproducts, dyework, roofing and road-surfacing materials, will be established and colonized in Kentucky, in close con-

junction with the coal industry, which will derive a great benefit thereby."

M. L. Fellmer, safety engineer, T. H. Masten & Co., then discussed "Human Engineering," which he regards as a better word to use than "welfare." Everyone is seeking a synonym for that unhappy word, though it is really not so unfortunately chosen as is generally thought. We may well presume that "human engineering" will not be any more than a temporary solution, seeing that the comparison of a man to a machine which the expression contains is far more objectionable than the implications in the word "welfare." Every word expressing benevolence has to be changed almost every decade, because the older words have become offensive by their use in connection with acts of pretense and grandiloquent phrases. "Welfare" is a homely word which might well be used, if the work it expresses is done with due regard for the sentiments of the people who profit by it. If the manner of the engineering is offensive, "human engineering" will soon be more accursed than "welfare."

A. H. Reed read a paper on "Zinc and Lead in the Kentucky - Illinois Fluorspar District," a paper which, while a distinct contribution to the literature of the subject, had little appeal to men in the coal industry, and in fact was somewhat too erudite for any but a metal-mining geologist.

Col. G. A. Burrell, who was to have read a paper, was called away to the Baltimore Tunnel at Wilkes-Barre, the scene of the recent powder flareup. He was replaced by H. D. Mason, who read an article entitled "Gas and Coal Dust in Mines." H. M. Wilson addressed the meeting on "Schedule Rating of Coal Mines for Workmen's Compensation." He made the important announcement that the Associated Companies purposed to put in operation a combined system of schedule and experience rating in which the rate would be based on the past experience of the underwritten company as well as on its provisions for safety. The schedule rating was made supreme and exclusive by the Associated Companies when the field of workmen's compensation was first created in the United States, and for this reason: There were no statistics that would give a true experience rating or permit the establishment of a rating based partly on absence of physical hazards and partly on experience. Now, however, with the larger companies there have been established statistics sufficiently tangible to permit of venturing on experience rating. However, small companies, whose limited operations made their misadventures appear unduly large or the lack of misadventure unduly important, could not even now be said to have established a reliable experience rating. The averaging of adventitious happenings by breadth of experience had not in their case been sufficiently complete.

The laws of probability have come into full averaging effect with companies with many and large operations, whereas with small companies and a single operation nothing but time will tell the tale. The rating of a large company might be advantageously fixed by the experience of 18 months, but the small concern would not reach a similar basis till its accidents had been tabulated and evaluated over a period of five years.

Some controversies arose as to the origin of schedule rating in workmen's compensation and as to the reliability of the different types of insurance—reciprocal and old line. Reciprocal insurance in the workmen's compensation field has not suffered from as many lapses as in the life or fire insurance fields. There are indicia that this may continue to be the case. A more prudent handling of reciprocal insurance is growing up, and the companies buying workmen's compensation insurance are more prudent and farseeing than many individuals who in the past bought life or fire insurance policies on the mere strength of the appeal of the chromolithography with which the policy was emblazoned or on the personality of the agent who presented the insurance company's claims.

> Purchasing agents are asking for figures on coal which will exhibit the proneness or indisposition of a coal to slag on the grates and make combustion difficult. Those figures are being secured by the United States Bureau of Mines for coals all over the country. Meanwhile microscopic inquiries are going on, so that we will eventually learn the nature of the wonderful complexity of material which constitutes coal.

The test of insurance comes with bad times. Unprofitable operation of the coal mines is apt to bring cancellations. An unfortunate multiplicity of accidents or a big disaster is likely to have the same result. The company is then faced with large expenditures while receiving no new accretions of capital. There is no reason why a reciprocal company should not provide against such contingencies by a large pool of resources. As a matter of fact this is not generally done in this type of insurance. But it by no means follows that this baleful inefficiency of reciprocal insurance in other lines will be followed in workmen's compensation. In fact, so far, since the companies have been working under a compensation law, and not under the common-law provisions for compensation, no reciprocal company has failed.

The last paper in the afternoon session was perhaps the best. Major A. C. Fieldner had the pleasure of describing his own important tests on the fusibility of coal ash and Dr. Thiessen's remarkable microscopic inquiry into the partly mineralized agglomeration of vegetable matter that we call "coal."

Major Fieldner has not yet made the coal industry sit up and take notice of the importance of his fusibility tests, but the manufacturing world is about ready to awaken the coal industry by calling its attention to Major Fieldner's work. The purchasing agents of the manufacturing concerns are keenly anxious to know how readily the ash will fuse in the coal that they are examining with a view to purchase. The president of the institute, it may be said, made careful note of the high temperature at which the coal he is producing will fuse in the furnace, and not a few learned for the first time the importance of facts which have been available to them for a long time in the pages of *Coal Age*.

In an early issue of *Coal Age* Major Fieldner's remarkable contribution to the proceedings of the institute will appear at length. Thiessen's work for a long time looked like a long labor lost. He spent years trying to begin to make his astounding micrographs of coal. It is not easy to slice and grind coal to such a thinness that common light will penetrate it. The time has not arrived that Mr. Thiessen can do this with anthracite, but lignite, Illinois coal and later Pennsylvania coal succumbed to the persistence of his brilliant technique, and the result is photomicrographs of startling brilliancy setting forth a story such as Thiessen alone perhaps can adequately interpret. The masses of vegetation called coal are themselves perhaps the best paleontological evidences of horizon. We are not dealing with a few roof ferns, but with vegetation in mass.

It is likely that we shall be able now to tell just what bed we are mining and solve many knotty problems and even some lawsuits in regard to the correlation of coal measures; though as someone stated, perhaps there was a variety in vegetation with location in any one moment of past time just as there is now. The sycamore rarely passes a certain line. However, temperature conditions were probably more equable, at least in Carboniferous time, and the surface of the coal bog more nearly level than is the case with our modern topography.

The institute held a luncheon in the evening at which H. M. Ernst read C. D. Burdick's paper on "Depreciation and Depletion." Mr. Burdick suggested in his address that depletion might be treated as decreasing with time, for the most easily available and operable coal is depleted first, and the load placed on early operation should be of such a character as to lighten the load on later production, when long hauls and expensive maintenance make the duty of keeping down costs an insuperable burden.

Mr. Burdick desired also to put de-

preciation as a function of tonnage instead of time. It is a fact that both depreciation and obsolescence continue their fatal work when a machine is idle. During a long or short shutdown every kind of equipment is growing old and out of date. However, if the burden is put on tonnage and not on time, the operator is less disposed to run his mines at a loss when business is bad. The temptation to run mines to reduce the losses of idleness is now only too strong. Minimum royalties, overhead, insurance and many other costs are factors of time. If they could be made by any provision factors of production, to be a charge on working mines only, then they would discourage the operation of mines at a loss.

It is a fact that many forms of depreciation are accelerated by idleness, and that much idleness is of such uncertain duration that care cannot be taken to cure that disadvantage. For instance, an idle machine can hardly be brought out when no one knows how soon the mines will start again. So the machine is left in the mine unheated by use and tends to depreciate. Moreover, many machines are worked when the mines are idle — pumps, for instance. It seems, therefore, that while depreciation by tonnage may have some financial advantages and even some argument in its favor, depreciation by time is the preferable plan.

At the conclusion of Mr. Ernst's remarks R. Dawson Hall discussed the question, "Has the Metal Industry Any Lessons for the Coal Industry?" He called attention to the excellent results —21 tons per man-shift—obtained by the Inspiration Consolidated Copper Co., which works on a day-work basis. He compared the efficiency of daymen and miners and pointed out that, owing to the lack of coördination between miners and management, the miners in coal mines were not nearly as efficient as the daymen who received more adequate equipment from the manager and more alert attention from the foreman. Miners are often found idle, but if daymen are idle the foreman is on tenterhooks.

He also showed how on railroads some firemen who are largely paid by the hour exerted themselves over-much in the performance of their duties, causing a waste of fuel. The comments made at the recent meeting of the International Railroad Fuel Association showed that the anxiety of the engineers and firemen to keep a hot fire at all times caused a considerable loss to the railroad companies. It was by no means established that the daymen would do less than the men who received payment by the piece, where there is proper supervision, sufficient encouragement in the performance of the work, suitable machinery and adequate support in the performing of their duties. These desiderata are all found with day labor. The operator finds it pays to supply them and somehow contrives to do so. With tonnage payment the operator coöperates only with a few of his men and employs only such a day-laboring force as will result in the utmost efficiency in the work of that force. He does not coördinate with the men as a whole, and so the mining operation is efficient only in spots and fails of ultimate efficiency. Time prevented extended discussion, there being an address by the chief inspector, Prof. C. J. Norwood, to follow. Professor Norwood discussed the distribution of production among the various counties and districts of Kentucky, and the number of accidents according to a similar distribution.

The following morning, articles with illustrated views were presented as follows: "Mine Rail Bonds," by C. C. Beck; "Storage Battery Locomotives in Mine Work," by J. Appleton, and "Permissible Explosives," by J. E. Miller. Frank Morris, field secretary of the National Safety Council, presented succinctly the claims of the council for the support of operators, urging the ability of that organization to support the managers in their safety plans. He said that in safety the operator found the best ground on which he and his men could work for a common end without any antagonistic points of view. Both wanted safety, and the success of the one did not hamper the other but helped him to attain some of the best objectives. Consequently, safety was the best basis for coöperation and the starting point for a coördination that might ultimately cover for both operator and mine worker the whole work of production.

Officers for Coming Year

THE institute elected the following officers: President, H. M. Ernst, general manager, West Kentucky Coal Co., Sturgis, Ky.; vice presidents, Alexander Frost, superintendent, North Jellico Coal Co., Wilton, Ky.; John P. Gorman, general manager, Hazard Coal Co., Lexington, Ky.; J. Henry Hall, president, Whitesburg Coal Co., Whitesburg, Ky.; H. H. Small, sales manager, Goodman Manufacturing Co., Chicago, Ill.; A. G. Spellman, assistant manager, St. Bernard Mining Co., Earlington, Ky.; R. C. Thomas, superintendent, North East Coal Co., Paintsville, Ky.; H. H. Townsend, Jeffrey Manufacturing Co., Athens, Ohio; Louis Francis, general manager, Lick Branch Coal Co., Coxton, Ky. The reëlection of C. W. Strickland, general manager, Ashland, Ky., to the office of secretary-treasurer was, in view of his popularity and energy, a foregone conclusion. The institute is to be congratulated on his willingness to retain the office.

The afternoon was spent in the Stoll athletic field in a somewhat hastily improvised first-aid contest, but one which was extremely successful. There were many who thought that the war, which has thinned out organizations for first aid, has made practice difficult or done away with it altogether, and has furnished an excitement that made it difficult to hold teams together, would prevent a successful meet being held. However, inquiry proved that such conditions, while they existed, did not prevent a great interest being shown in the event. The program was as follows:

One-man Events: (1) Man has been overcome by gas. It is impossible for bearer to stand erect in carrying him. Carry him 20 ft. to place where bearer can assume erect position; then carry 20 ft. by shoulder-carry. Perform artificial respiration by Schaeffer method for one minute. (2) Man found unconscious on charged electric wire; burned on right hand and forearm.

Two-men Events: (1) Simple fracture of right forearm and scalp wound on back of head. No bleeding. Treat and carry patient 30 ft., without using a stretcher. (2) Compound fracture of right forearm, with punctured wound in the palm of the right hand, which is bleeding profusely. Treat.

Full Team Events: (1) Man has been run over and right arm cut off close to the shoulder; profuse bleeding; several ribs broken on right side. Treat, and carry on a stretcher. (2) Man overcome by gas, requiring immediate removal. Burns on hands, arms, neck and face. Carry patient 10 ft. on an improvised stretcher. Two of the team at a time should be supposedly overcome by gas. Remainder of team carry patient, without a stretcher, for 20 ft. to fresh air and treat the case. (3) Man has been rescued following an explosion and has sustained the following injuries; burn of back of head and neck, simple fracture of right leg below the knee, and compound fracture of the kneecap of the left leg. Treat.

In the full-team event the first prize was awarded to the Jenkins team of the Consolidation Coal Co. They received the "Institute Plaque" of silver, which was won in 1917 by the team of the Stearns Coal and Lumber Co. It will hold the prize a year and the name of the team will be engraved on the back of the plaque. The Phoenix Hotel cup was awarded to the same team, and the institute, having by a collection in the morning session raised $300 for that purpose, promised to pay its expenses to the Bureau of Mines dedication exercises at Pittsburgh. The team will be the champion of Kentucky on that occasion.

The same fortunate fellows each received Red Cross medals for their efficiency. The W. G. Duncan Coal Co. team received $25 as award for being in second place in the contest, the Stearns Coal and Lumber Co. team took third place with $15 and the Federal Coal Co. was fourth and received $10.

The two-team event was won by the W. G. Duncan Coal Co., first; the Federal Coal Co., second; the Stearns Coal Co., third; the Consolidation Coal Co., McRoberts team, fourth.

The one-man event was won by the Federal Coal Co., first; the Pioneer Coal Co., second; and the W. G. Duncan Coal Co., third. The Consolidation Coal Co. had no less than six teams entered. Dr. J. W. Pryor was chief judge and he had six judges under his direction. The contest was under the auspices of the American Red Cross.

Preparation of Bituminous Coal—V

By Ernst Prochaska
Benton, Illinois

SYNOPSIS—*Many features are common to all jigs, and the materials of construction are confined to wood, steel plate, cast iron and reinforced concrete. Each of these has its own advantages and disadvantages. The jigging of fine coal has always been difficult, and for this purpose the concentrating table has many advantages. Such tables also give good results when used upon crushed middle products of the jigs.*

UPON the character and nature of the raw coal depends the selection of the proper type of jigs, as well as the methods to be followed in washing the coal. The different methods have been explained previously, so that we can confine ourselves to a short review of the most important differences existing in the materials used for construction, the methods of drives, apparatus for the discharge of the products and the arrangement of the jigs.

Jigs built of timber are light in weight and cheap in first cost. The jig boxes can be repaired and even totally rebuilt at the washery. But they are hard to keep tight and not very durable. The best wood for the construction of jig boxes and tanks is long-leaf yellow pine of heart specification. In some instances creosoted timber has been used. Timber construction is especially advisable if the wash water becomes acidulous.

Jigs built of steel plates are comparatively light but expensive. They must be stiffened with angle irons and braces to keep the side plates from breathing.

Cast-iron jigs appear to have the preference at present. They are rather heavy but stiff and solid. They are not affected by acidulated water and always represent the value of scrap iron, if for any reason it becomes necessary to change the type of jigs.

Reinforced concrete has been used in several instances in the construction of jig tanks. This material, however, has the great disadvantage that it is affected by acidulated water to a highly disastrous degree. The solid, heavy construction of reinforced-concrete tanks prevents also any changes or alterations. A reinforced-concrete jig tank must remain the way it has been put up in the first place, or it must be entirely rejected if changes become necessary.

The proper selection of the material of which jigs should be built depends on cost of construction, cost of upkeep, nature of the wash water and the design of the supporting structures.

Side or end plungers actuated by eccentrics give, under normal conditions, perfect satisfaction. If the coal is difficult to wash a differential motion drive for the plungers would be advisable. In cramped quarters considerable space can be saved by the use of plungers placed below the screens. For extremely large jigs compressed air can be used to advantage.

The discharge of washed coal is similar in all jigs.

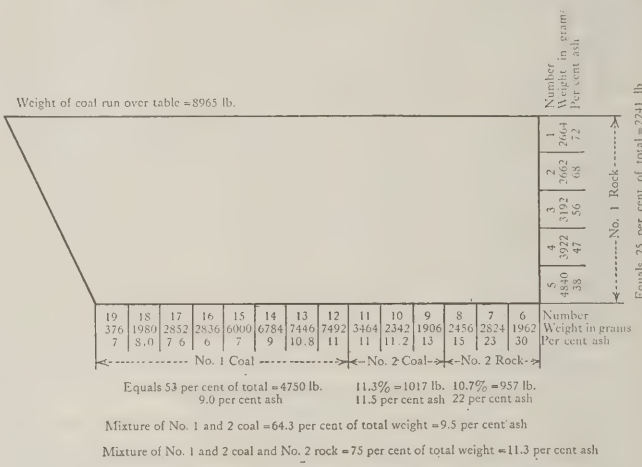

FIG. 10. SEGREGATION OF PARTICLES ACCORDING TO SPECIFIC GRAVITY

It consists of a simple overflow dam or weir. The discharge of refuse, however, shows many variations and has been elaborated previously. For jigs treating unsized or the larger sizes of coarse coal plain gates can be used. This type is almost universally employed on reciprocating jigs. The gates can be either of the slide or swing type. The swing gates offer some advantages over the slide gates as they permit the removal of the heaviest pieces of refuse without disturbing the bed.

The kettle or pot valves are to be recommended for coarse-coal jigs. They permit a close regulation of the slate bed and have the further advantage that they prevent an accidental loss of the slate bed, caused by

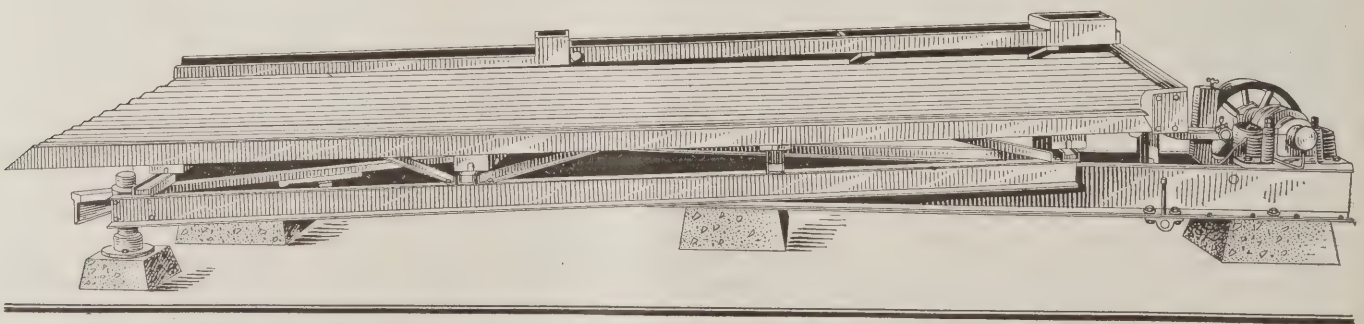

FIG. 11. DETAILS OF CONCENTRATING TABLE USED FOR REWASHING MIDDLE PRODUCTS OR SLUDGE

FIGS. 12 AND 13. HOW IMPURITIES ARE DISSEMINATED IN COAL

inattention of the operator. The kettle valve being open on top permits an inspection of the refuse. The double slate gate is nothing more nor less than a developed kettle valve extending over the whole width of the jig. It is at present the best design known, as it combines the good points of the kettle valve with those of a slide gate.

Revolving slate valves are only to be used for fine-coal jigs, as the heavy refuse accumulating in coarse-coal jigs is apt to choke up this type of valve. For the removal of the fine refuse passing through the perforations of the screens, a common molasses gate is the simplest and best device. Other types of mechanically operated valves for the discharge of hutch work have been designed, but they all appear to be entirely too complicated.

To facilitate the operation and supervision of the washing process it is desirable to locate all the jigs, including the rewash machines, on a common platform.

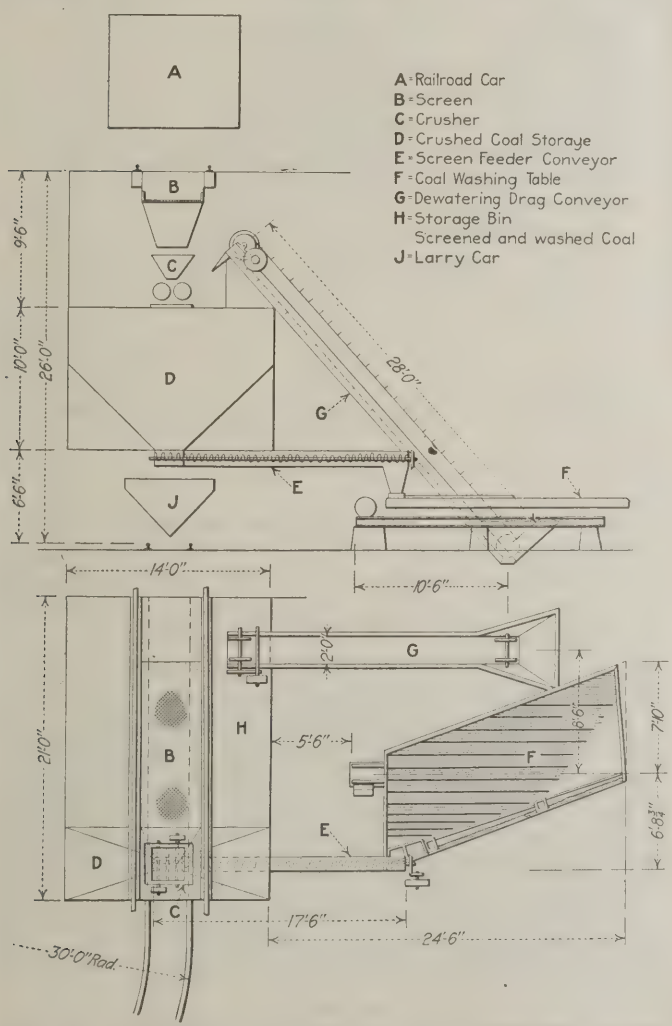

FIG. 14. PROPOSED LAYOUT OF COAL-WASHING PLANT

This permits the consolidation of a number of jigs in a battery thereby saving space and cost of installation. The rule is to provide each compartment of a jig with one separate plunger. If one plunger should be used for two compartments, there would be great danger that the jig work of these compartments would be uneven and unsatisfactory. The second compartment is treating quite different material from the first, and as explained previously length and frequency of plunger stroke must be adapted to the material to be treated. So it can be clearly seen that it will be absolutely wrong to treat two different materials with the same kind of pulsation. The jigs should be placed in such position that they will be accessible from all sides; and to facilitate the inspection of the work performed they ought to be placed somewhat higher than the operating platform.

The products delivered from the jig cannot be used without further treatment. All the products require a more or less extensive and difficult subsequent preparation before they can be placed on the market. This after-treatment depends largely upon the size of the coal. Coarse coal must be dewatered, classified and delivered into the loading or storage bins, avoiding thereby breakage and abrasion as much as possible.

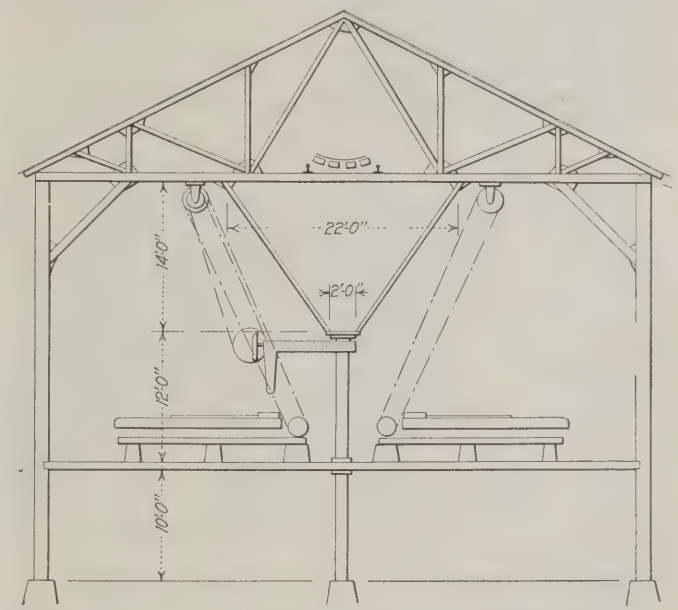

FIG. 15. ELEVATION OF TABLE COAL-WASHING PLANT

Fine coal must be dewatered and delivered into the bins or railroad cars. Middle products are either first crushed and then delivered to rewash jigs or are delivered to these machines without previous crushing. The refuse from the rewash jigs is combined with that from the primary jigs, and the washed coal is either mixed with that from the primary jigs or separately stored in bins as boiler-house fuel, according to its degree of purity. The wash water must be clarified before it can be put back into circulation.

The sludge recovered by the process of water clarification can be subjected to a further treatment, but in any case it must be dewatered before it can be mixed with the washed products. If the sludge is of such a character, however, that subsequent treatment will not improve it, it must be wasted and thrown on the refuse dump.

The refuse is delivered into refuse storage bins and from there by means of self-dumping cars or similar

devices carried to the dump. Before delivery into the bin, however, the refuse must be dewatered by means of a perforated bucket elevator, the overflowing dirty water is clarified and put back into circulation. The resulting sludge is deposited on the refuse dump. If the refuse contains pyrites, a separate installation for its recovery would be advisable. The economic value of such a plant, however, would depend a great deal upon the market value of sulphur.

For the washing of coal too fine to be treated successfully on jigs, concentrating tables are coming into use. Such tables have been employed for many years in ore-dressing plants, and the principle applied for ore concentration can also be used for coal washing. The specific gravity of the material and the size of the grains are two of the most important considerations. Specific gravity comes first and size of grains is second in importance.

Many types of concentrators for fine material have been developed, but among them the machines with the separating surface in motion and having a continuous feed and discharge are the most important. The machines belonging to this group utilize mechanical agitation to separate the grains into layers. The pulp, in its passage across the table deck, stratifies, in accordance with the specific gravity of the different particles, the heaviest seeking the lower strata between the riffles, while the coal or lighter particles remain on top, to be washed off the side of the deck by the cross flow of wash water, the heavier, or high-ash grains, being guided by the riffles and advanced to the end of the deck by the head motion and discharged as refuse. This separation is visible at all times while the table is in operation, and susceptible of exact adjustment and under easy control of the operator.

Concentrating tables for coal use riffles on the table deck. These riffles are produced by tacking cleats on the table surface. The arrangement of the riffles forms at present the main difference between the different tables. Other differences can be found in the manner in which the shaking motion of the deck is produced. In any case the backward motion should be faster than the forward motion. The movement is either parallel to the direction of the riffles or the riffles are placed at an angle to the direction of the table motion. In some cases this angularity of the riffles is only carried on for a short distance in the middle of the deck. Whatever the direction of the riffles, the table motion moves the material toward the refuse side of the machine. The refuse collected on the bottom of the riffles is carried forward faster than the clean coal forming the upper strata of the bed. The wash water, however, washes the clean coal down the slope of the table much faster than the deeper stratified refuse.

In ore dressing the line between concentrates and tailings can be usually clearly defined, but with coal this is not possible. Between clean coal and pure refuse

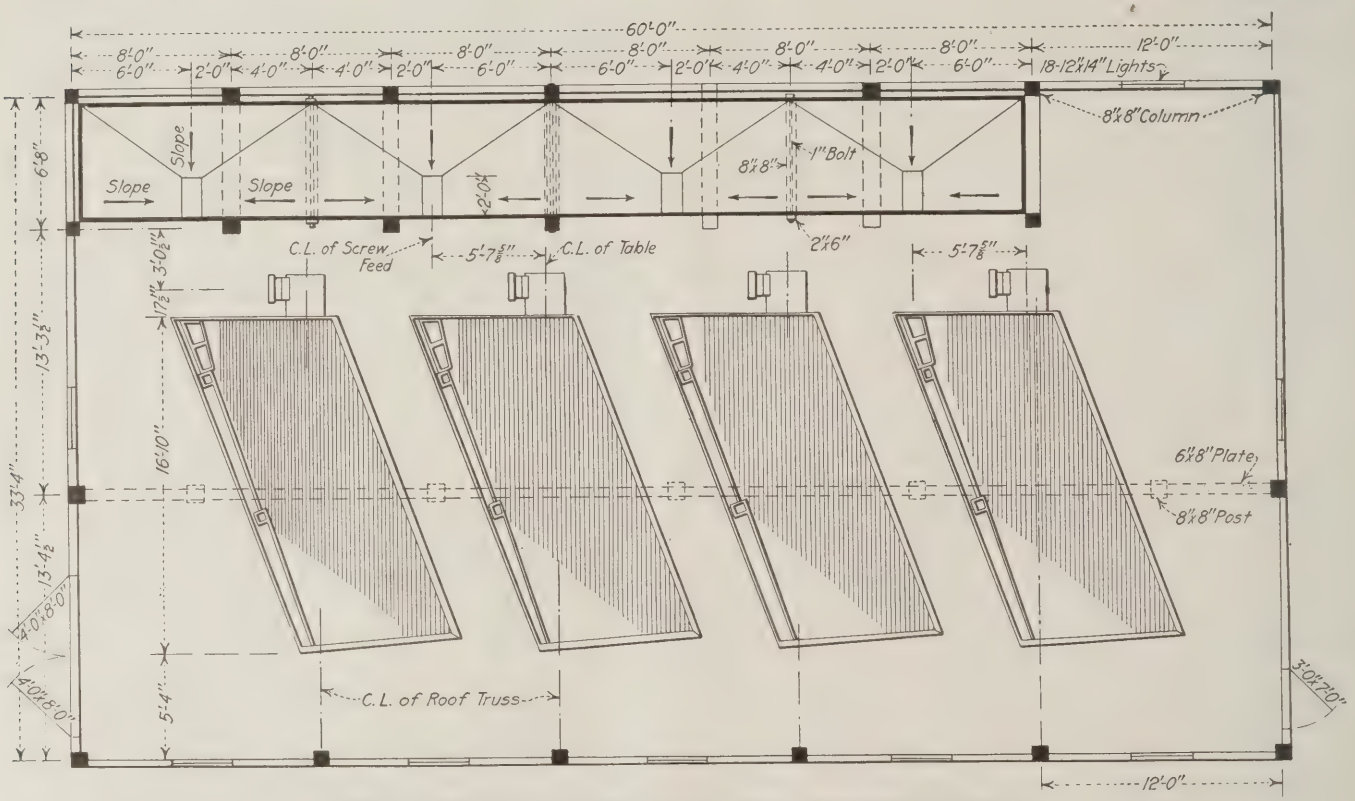

FIG. 16. FLOOR PLAN OF A TABLE COAL-WASHING PLANT

we find a more or less wide area containing the so-called middle products. Therefore it becomes necessary to make either three products or to establish the division between coal and refuse at the most economical and efficient point. Fig. 10 shows clearly the segregation of the particles according to their specific gravity, which is influenced by the amount of ash.

The materials contained in raw coal do not show an increase in specific gravity by clearly pronounced steps. The specific gravities increase by infinitesimal increments, and if we plat the specific gravities of the different materials we will get a continuous ascending curve and not a broken straight line interrupted by distinct steps.

The proper washing of fine coal has for a long time been an uncertain undertaking. With the advent of concentrating tables, however, the difficult problem of washing fine coal has been solved in a satisfactory manner. With coking coal there now exists the possibility

of abandoning the use of jigs entirely, by crushing all the coal to the required fineness and treating it on tables. This fine crushing will liberate more effectively the bone coal, and tables will therefore produce cleaner washed products. The reason for the foregoing is obvious. The finer the coal is crushed the more complete is the physical separation of coal from its impurities, and it only remains now to accomplish the segregation of the coal from them.

Tables require little power, about 1 hp. is sufficient to operate one table. The supporting structure for a table can be much lighter than for jigs, and the building housing such machines does not need to be so massive. Figs. 11, 18 and 19 show a concentrating table adapted for coal washing.

Besides primary washing, tables can be used to good advantage either for the rewashing of recrushed middle products or for the rewashing of the sludge recovered from the water clarification. For this latter purpose a slightly different type of machine should be used, resembling the slime tables used in ore dressing. Concentrating tables can be used economically at every

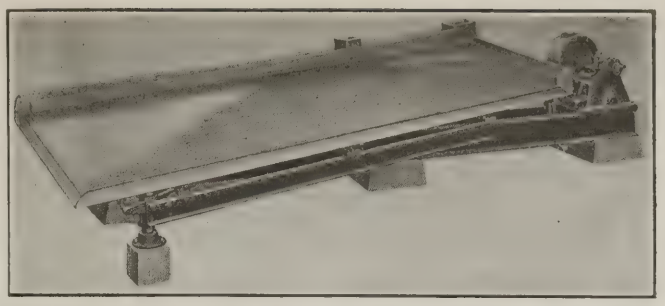

FIG. 19. CONCENTRATING TABLE ADAPTED FOR COAL WASHING

ity tables are equal to jigs treating the same kind of coal. Outputs up to 12 tons per hour have been recorded for one table. Fig. 10 indicates clearly the manner in which the separation is effected on one of these machines and shows the possibility of making any kind of washed product or refuse by simply dividing the outflowing product at any desired point along the side or end of the table.

washery, and at present they represent the most feasible apparatus for treating fine coal and sludge. They unquestionably offer many advantages in an economical as well as purely technical way.

The cost of installation is low, they require less expensive buildings and foundations than jigs. The cost of operation is considerably less than that of jigs on account of the small power required, the reduced wear and tear and less supervision. One operator can watch twice as many tables as jigs. In regard to capac-

The great advantage of a table lies in the fact that the process of separation is immediately before the eye and any desired change can be made without interrupting the operation. The outflow of the materials is visible, and by a judicious regulation of the stroke, the water supply and the slope of the table, the operator has full control over the process.

When retreating middle products the materials to be crushed consist of washed but intergrown coal from $\frac{5}{16}$ in. to 3 in. in size. The purpose of crushing is to break up the intergrown particles in such a way that the slate or bone adhering to or disseminated throughout the coal shall be mechanically separated from it. This will give a homogeneous mass of material suitable for rewashing.

Two considerations must be taken into account. The character of the middle product influences, at least in a theoretical way, the crushing process. The most suitable method would be, without doubt, to spall off the slate and bone without crushing them. This would make the subsequent water clarification and sludge recovery much easier. But the foregoing procedure would only be possible if the impurities are attached to the coal as shown in Fig. 12. This condition occurs only in solid coal, where the impurities are to be found at the cleavage line between the bed of coal and

CRUSHER DATA

Type	Crushing — From	Crushing — To	Capacity per Hour in Tons	Power Required
Roll crusher	3 in.	$\frac{3}{16}$ in.	6 to 60	3 to 25 hp.
Gyratory crusher	3 in.	$\frac{1}{16}$ in.	1 to 12	2 to 20 hp.
Disintegrators	3 in.	65 mesh	3 to 85	2 to 150 hp.

the roof or the bottom. In most cases, however, we must consider impurities, which are more or less disseminated throughout the coal mass, as shown in Fig. 13. In this case a crushing of the impurities cannot be avoided. (2) In every case the degree of crushing—that is, the difference between the size of the material before and after crushing—must be made as small as possible. The crusher giving the greatest yield with the smallest amount of sludge is the one most suitable, because this permits the most perfect separation. Whether, in each separation case, the yield or the amount of sludge should be considered more important depends on the one hand upon the difficulty of water clarification and on the other hand upon the value of the fine coal.

The crushing plant ought to be located between the primary and rewash jigs. This will necessitate the installation of an elevator, because all the jigs should be located upon one platform at the same level.

The crushing of the middle products can be accomplished either with roll crushers, gyratory crushers or disintegrators. Roll crushers can have either smooth or slightly corrugated rolls. Such crushers will permit the free passage of flat pieces of slate, which affords a decided advantage over all other types. For crushing down to $\frac{3}{16}$-in. size, roll crushers are well adapted. If the middle product should be crushed still finer, gyratory crushers or disintegrators are advisable. Gyratory crushers can be used down to $\frac{1}{16}$ in. size, and for still finer crushing disintegrators should be employed.

The process of rewashing does not differ materially from the process used in primary washing. The regulation of the rewash process depends upon the purpose for which the resulting products will be used. If, according to the character of the middle product, only boiler-house coal can be made, close washing is not necessary and the rewashing should be carried on in such a way that the resulting refuse will be as free from good coal as possible. If, however, the middle product is of such a nature that the pure coal contained therein is good enough to be mixed with the primary washed coal, the middle product should be washed very closely. In some cases it would be more economical to rewash for boiler-house coal only, even though the product of the rewash jigs could be made clean enough to be mixed with the primary washed coal, on account of the great loss of good fuel in the refuse, imposed by trying to get a perfectly clean washed product.

(To be continued)

Steam-Operated Coal Conveyor from Tipple to Boiler House

THE most economical method of conveying screenings from tipple to boiler house is a problem that has often been discussed. The most satisfactory solution has never yet been found. Many mines employ various forms of flight and carrier conveyors, driven by steam or electrical power. Others use the old-fashioned method of car and track. A small dump car filled with screenings is pushed to the interior of the boiler plant, where it is dumped before the boilers.

The American Steam Conveyor Corporation has adapted its steam ash conveyor so that it can be used for handling boiler coal. The conveyor thus constructed consists of a line of pipe extending from a point directly under or alongside the screenings hopper in the tipple to a discharge point in the boiler room. The coal is fed into an intake in the pipe and is carried to the discharge point by the action of an air current.

This current is created by the action of a jet of high-velocity steam discharged into the center of the pipe line in the direction of travel of the coal. This steam discharge tends to create a vacuum behind it, which in turn creates a current of air through the air intake in the line.

The coal intake is located conveniently before the tipple hopper, so that a laborer can rake the coal into the intake with small effort. The powerful suction pulls the coal through the system toward the "steam unit fitting," that point where the steam is introduced into the system. Here the force of the steam ejects the coal along the "discharge line" of the system.

When coal is needed in the boiler room a laborer opens a steam valve, allowing the steam to enter the system. The coal is then shoveled or raked into the intake tee, where the air current whisks it to the disposal point in the boiler house.

This disposal point may be a large bin or hopper in the top of the power plant, or it may simply be a target box with long spouts through which the coal is withdrawn to the boiler-room floor below. Since the delivery spouts are movable there is little trouble in placing the coal exactly where it is needed.

The manufacturers of this system claim that it is one of the most economical and efficient yet devised. The steam cost per ton of coal handled is exceedingly small, as the steam is used only when the system is in actual operation. The labor cost is likewise low, as one man can quickly shovel enough coal into the intake tee to supply the boilers for a long time.

Coal Age Is in Receipt of the Following Letter:

Promotion of Friendly Relations with the New Nations of Europe

I AM wondering whether we cannot enlist the assistance of many of our mine managers to inform the foreign-born Americans in their employ that Mr. Hoover, as Director-General of the American Relief Administration, has made it possible for individuals in this country to transmit funds to their relatives in Finland, Poland, Czecho-Slovakia, German-Austria, Jugo-Slavia (including Serbia), Rumania and Turkey.

In securing this exclusive privilege from the Federal Reserve Board, the Government has been chiefly interested in reëstablishing the banking connections between the newly liberated countries and America. It is the first concrete move that has been made to put these people on their feet.

As I look upon the intervention of our Government in Europe, it can be divided into four distinct stages: First, armed intervention; second, suggestion of peace terms which finally led to the signing of the armistice; third, supply of relief to the liberated countries; fourth, reëstablishing of commerce between the liberated nations and the outside world.

Each successive stage represents the natural advance beyond the preceding stage, and all constitute a logical sequence of overlapping steps. For instance, armed intervention against Germany, even if successful from a military point of view, would not of itself have attained our full purposes in entering the war. Having effected the isolation of Germany, we had to endeavor to secure a satisfactory arrangement as to geographical division of territory. With this in the way of accomplishment, we could not abandon the new countries thus established without making some effort to supply them with food.

Having drawn upon our stocks of food in America and placed these supplies at the disposal of the liberated countries in order to meet their requirements until their own harvest becomes available, we shall not have fulfilled our entire obligations unless we make some effort to reestablish commerce.

Commerce is fundamentally dependent upon definite financial relations between countries that hope to do business with each other. The development of the fourth stage of American intervention, therefore, has its beginning in the plan that has been worked out by Mr. Hoover by which the banks in America are offered immediate contact with the banks in the liberated countries, through the medium of the American Relief Administration. Beginning Apr. 22, this new arrangement afforded foreign-born Americans the opportunity to forward individual money gifts or payment of money to firms, persons, institutions or relatives at home. It was expanded in May, so that drafts could be purchased on home banks, and travelers could leave America with the satisfaction of knowing that their dollars here had a definite value in the currency of their own country at home.

It is obvious that it would have been impossible in the early stages after the armistice to set up any such banking relations without the intervention of the Government, and this was made possible by the relief work of the American Relief Administration in Europe. But this is merely a stepping stone to permanent commercial arrangements, and the foreigners in America are asked to support this exchange system now as it represents the definite beginning of financial connections between this country and the liberated nations. While it is chiefly represented at the present moment in the transactions in food, it will gradually be transformed into transactions covering other commodities and lead to definite trade relations. It is prohibited by law to send money by any other medium, and no one of foreign birth can justify using any other means for sending money to his relatives, as the support given by him to the American Relief Administration in this work is indirect support of his own Government as well as that of the United States in its effort to complete the fourth and final step of its intervention in Europe.

In order to promote this commendable enterprise, *Coal Age* has donated a page advertisement on this subject, which appears in this issue. The advertisement has been put in such a form that coal mine managers may cut it out and post it on their bulletin boards for the general information of their employees, and we urge that this be done. Also, we urge readers associated with companies employing men of foreign birth to cut out this page from their copies of the paper and hand it to the manager so that an ample supply of these notices may be available at each mine and works—EDITOR.

Anthracite Mining Costs

By R. V. Norris
Wilkes-Barre, Pennsylvania

SYNOPSIS—*On account of the greater range of sizes and prices received for anthracite coal, the fixing of a fair price for this fuel was somewhat more complicated than was the establishment of a reasonable price for bituminous. Decreased margins of profits during the war period were absorbed by the coal producers themselves.*

IT WAS stated in a former article[1] that an intensive study of anthracite costs was being made by the engineers of the United States Fuel Administration. The results of this study are now available and are offered as a supplement to the former paper. Anthracite costs as reported for the six-months' period, December, 1917, to May, 1918, inclusive, as compiled by the Federal Trade Commission, were used as a base, and charts similar to those described in the former article were made for the standard white-ash anthracite and for red ash and Lykens Valley coals. The adjustments of cost from a reported to a price-fixing basis, as described for the bituminous methods, were applied but showed only minor adjustments as necessary.

The great spread in anthracite prices on the varying sizes, which for the six-months' period under review ranged in average from $5.244 for nut to $2.074 for barley coal, makes the question of the percentage of sizes produced at the different collieries a vital one. The realization with the same prices for each size must be within wide limits, when it is considered that the percentage of prepared coal reported from different collieries varied from over 80 per cent. to below 30 per cent. for fresh-mined coal. Hence, as the spread in prices for the various sizes must be predicated on some percentage, it is essential to find some method of adjustment to allow for this variation. The logical method of adjustment is to calculate actual costs to costs as of the standard percentage of sizes, so that the margin between the adjusted costs and the average realization shall be the actual margin for each colliery between its actual costs and actual realization due to its particular percentage of sizes. As a base for realization the actual percentage of sizes for fresh-mined coal for the six-months' period was adopted. This percentage is given in Table I.

TABLE I—PERCENTAGE OF SIZES OF FRESH-MINED COAL

Size of Coal	Mesh, in Inches: Through Round	Mesh, in Inches: Over Round	Percentage of Sizes: Fresh Mined	Washery	Fresh Mined and Washery
Broken	...	4½	6.8	0.4	6.2
Egg	3⅜	3¼	14.6	1.2	13.5
Stove	2 5/16	2¼	19.6	2.3	18.2
Nut	1⅜	1¼	24.7	10.1	23.5
Pea	...	¾	9.1	10.0	9.2
Buckwheat	...	½	11.6	21.4	12.4
Rice	5/16	½	3.2	14.9	4.2
Barley	3/16	5/32	4.9	27.5	6.8
Boiler	5/16	¼	3.9	8.8	4.3
Screenings	3/32	1/16	1.6	3.4	1.7

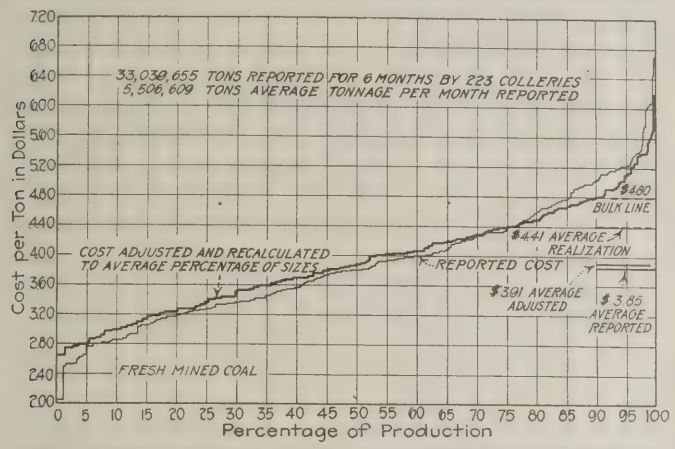
[1] *Coal Age*, Oct. 10, 1918.

For adjustment as a base for fixing a spread of prices the percentages used were, taken at even figures, prepared 65 per cent., pea 9 per cent., buckwheat 12 per cent. and smaller 14 per cent.

The adjustment finally arrived at after long study was tested on actual reports from collieries having percentages that varied from over 80 per cent. to under 30 per cent. of prepared coal and was found to be correct within a maximum variation of less than 1½ per cent. It was as follows:

For Each 1 per Cent. Variation	Above Standard, Per Cent. Deduction	Below Standard, Per Cent. Addition
Prepared	1.20	1.20
Pea	0.85	0.85
Buckwheat	0.75	0.75
Smaller	0.50	0.50

As examples of the working of this adjustment with prices assumed at about the average for the six months and taking mines well away from average percentage of sizes.



Size	Base per Cent. Sizes	Base Price	Realization	Mine A, per Cent. Sizes	Correction, per Cent.	Actual Realization	Mine B, per Cent. Sizes	Correction, per Cent.	Realization
Prepared	65	$5.10	$3.315	73.1	—9.72	$3.730	55.1	+11.880	$2.810
Pea	9	3.70	.333	6.4	+2.21	.237	15.3	— 5.355	.566
Buckwheat	12	3.20	.384	10.4	+1.20	.333	13.7	— 1.275	.438
Smaller	14	2.20	.308	10.1	+1.95	.222	15.9	— 0.950	.350
Totals	100	.....	$4.340	100.0	—4.36	$4.522	100.0	+ 4.30	$4.164
Assumed cost for each mine					$4.000				$4.000
Actual margin					$0.522				$0.164
Standard realization					$4.340				$4.340
Calculated cost as of standard per cent. sizes	$4.00 × 0.9564% =				$3.826	$4.00 × 104.30% =			$4.172
Calculated margin					$0.514				$0.168

The correction for Mine A is then —4.36 per cent. and the adjusted cost $3.826, showing 51.4c. margin on the $4.34 standard realization against 52.2c. actual margin. Similarly for Mine B, the correction is +4.30 per cent., giving an adjusted cost of $4.172 and a margin of 16.8c. as compared with the actual margin of 16.4c. Thus the adjusted costs on the chart bear a true relation to the realization received from a scale of prices for the various sizes based on the standard or average percentage of sizes adopted as a base, regardless of the actual percentage of sizes produced by each operation, and prices can be fixed from the chart line of adjusted costs which will result in giving each mine its intended margin. The correction, of course, is an allocation based on realization from the different sizes and could be made more accurately by taking into account each size produced, but at the cost of more time than was available for the work. With a material variation in price, different factors of correction should be calculated.

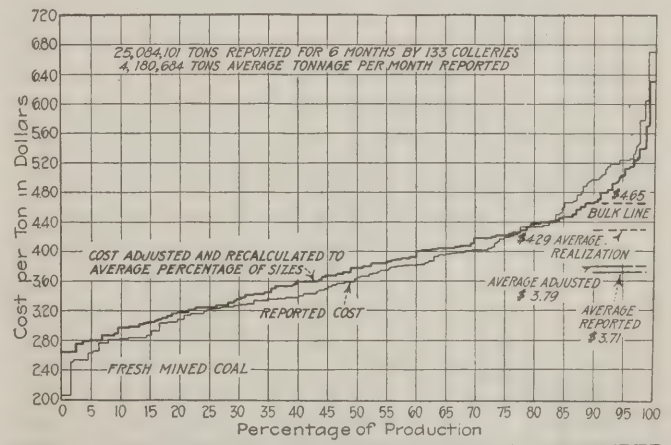
A large percentage of the anthracite coal is owned in fee by operators, who also lease tracts contiguous to their fee holdings. As all report royalties on the basis of tonnage produced, the general average 15.5c.

per ton reported is misleading. The actual average royalty reported by operators mining generally from leased lands was 33.25c., and by those generally mining from fee lands, 5.5c. As relatively few operators mine exclusively from either class of lands, no data are available to show the actual average royalties paid, but it is believed that the present average would be approximately 40c. per ton.

A few leases, notably those made by the trustees of the Girard Estate, owned by the City of Philadelphia, base the royalty payments on a percentage of the sale price of the coal at the mines instead of requiring fixed royalties; this percentage varies from 15 per cent. to as high as 28 per cent. of the price. As the labor war bonuses materially add to the sale price, these have

COST OF PRODUCTION OF ANTHRACITE FROM DECEMBER, 1917, TO MAY, 1918, INCLUSIVE

resulted in excessive royalties and serious embarrassment to the operators, who were not allowed to increase the price of coal sufficiently to even fully absorb this additional labor cost and by whom the extra royalties must be paid out of already narrow margins. Many of the lessors have patriotically foregone the extra royalties due under these sliding scales, and as it is certainly improper that the public should be asked to pay these additional royalties, not contemplated in the original contract though enforceable at law, the United States Fuel Administrator has expressed himself as unwilling to consider such excess payments in any fixing of anthracite prices.



Cost charts were made from averages of the six months, showing both the reported and the adjusted costs for standard fresh-mined white-ash anthracite, both by collieries and by operating companies. As, in the prices fixed by the President, Aug. 23, 1917, a differential of 75c. per ton on pea size and above, equivalent to 52.95c. per ton on all sizes, was established for the independent operators over certain companies with railroad affiliation, generally known as the "companies." Charts were made by collieries for both the independent operators and the companies, as well as a combined chart of the entire output. Similar charts were also made for the entire output of fresh-mined coal and for the total output including washery coal by operating companies, all collieries operated by a single company being consolidated. Similar charts were made for red ash and for Lykens Valley coal. These charts were interesting principally in that they showed that the higher prices charged for these specialties were justified by their higher costs of production. The charts given are believed to fairly show the general costs of production. These charts show the averages and bulk line costs for standard white-ash coal given in Table II. The average prices received are given in Table III.

The prices received by the companies and independents have not been separately averaged, but calculating on the differential and assuming the percentages the same for companies and independents, which is only approximately the case, the selling price of fresh-mined coal would average for companies, $4.287 and for independents, $4.817. Margins over reported costs of companies would be 58c. and for independents 45c. with a general average margin for all fresh-mined coal of 56c. and for all coal including washery of 71c. per ton, and under "bulk line" costs fresh-mined companies, 36c.; independents, 15c.; total, 39c.; including washeries consolidated sheets total of 7.5c.

These margins include all expenditures for Federal income and excess profit taxes, selling expenses, interest charges, expenditures for improvements and developments to increase output, excess of capital expenditures over normal cost, and all profit on the investment of about $8 per ton of annual output.

Effective Dec. 1, 1917, a labor war bonus, ranging from 60c. to $1.10 per day for labor and 25 per cent. for contract miners was granted over and above the wage scales effective by agreement Apr. 1, 1916, expiring Apr. 1, 1920, and the prices fixed Aug. 23, 1917, and modified Oct. 1, 1917, by reducing pea coal 60c. per ton, were increased by 35c. per ton to compensate for this labor increase. The actual reported increase in labor cost due to this advance was figured by the Federal Trade Commission from the operators' reports to be 60.3c. From the actual payroll figures later obtained by the United States Fuel Administration, this increase was found to be 76.3c. per ton.

Effective Nov. 1, 1918, a second labor war bonus

COST OF PRODUCTION OF "COMPANY" COAL, DECEMBER 1917, TO MAY, 1918, INCLUSIVE

was granted. The calculated increase in cost due to this is shown in one of the charts, on which the increases for each operator are found by figuring from the payrolls, for the six months, the actual increase in pay which would have been given applying the Nov. 1, 1918, increases, and dividing by the six-months' tonnage of the colliery. This line, adjusted to per cent. of sizes, plotted on the chart and compared with the adjusted cost, shows an increase in cost of 74.1c. As this was

necessarily applied to the prepared and pea sizes 70.6c. of the total increase on these sizes was $1.05 per ton, which increase was allowed to balance the increased cost of labor.

Price Fixing

Except for the two increases to compensate for labor increases just noted and the reduction, Oct. 1, 1917, of the pea coal price, the anthracite prices are as fixed by the President on Aug. 23, 1917. The present realization, all companies and all sizes, including washery coal and both the labor increases, is calculated to average $5.13 per ton, while the bulk line of the chart shown, plus the November, 1918, labor increase would be $5.32.

The capital invested per ton output in the larger

TABLE II. AVERAGE AND BULK LINE COSTS OF WHITE-ASH COAL

Chart Number	Description	Costs, Averages Returned	Costs, Adjusted	Cost, 90 per Cent. Bulk Line
	Excluding Washery Coal:			
81	All operations, each colliery separate	$3.85	$3.91	$4.80
82	All company operations, each colliery separate	3.71	3.79	4.65
83	All independent operations, each colliery separate	4.37	4.36	4.97
86	All operations, each company operating two or more collieries consolidated	3.85	3.91	4.38
91	Including Washery Coal: All operations, each company operating two or more collieries consolidated	3.57	3.77	4.36

and better-equipped collieries ranges from $5 to $11, with an average investment of from $7.50 to $8.

The prices fixed by the President Aug. 23, 1917, are given in Table IV. No price was fixed on sizes smaller than pea, which was decreased 60c. per ton Oct. 1, 1917. There was a general increase of 35c. per ton. Dec. 1, 1917, and one of $1.05 per ton Nov. 1, 1918. Sizes smaller than pea were limited to a maximum of 50c. per ton below pea coal by order of Nov. 15, 1918.

The present fixed prices, Dec. 31, 1918, per ton of 2240 lb., f.o.b. mines, are given in Table V. Smaller than pea is not to be sold within 50c. of maximum pea-coal price. Thus the selling price of anthracite has been increased but 30.5 per cent. over the pre-war price,

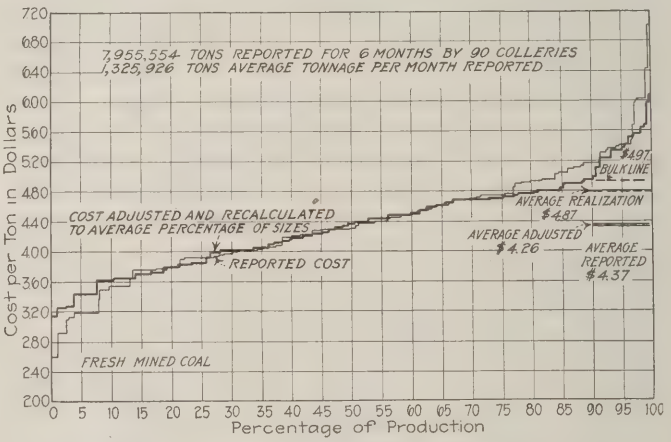
Total and weighted average small sizes	25.2	$2.795	76.0	$2.339	29.4	$2.697
Grand total	100.0	$4.414	100.0	$2.868	100.0	$4.285



while the cost of production has gone up 52 per cent., the difference having been absorbed by the operators.

The average cost as reported for the six months, December, 1917, to May, 1918, inclusive, prior to the increase of Nov. 1, 1918, but including that of Dec. 1, 1917, is given in Table VI.

Depletion of Lands—The proper charge for depletion is admittedly a difficult question. Under the present (1917) income-tax law lands purchased since Mar. 1, 1913, may be depleted to return the cost price on exhaustion and lands purchased before that date may be depleted on their value as of Mar. 1, 1913. The second class may be divided into those operated on royalty by others than the owners, where the depletion accrues to the owners, and those lands directly operated by the fee owners.

In the case of royalty lands the value as of Mar. 1, 1913, is clearly the present value as a varying annuity of the annual amount of the royalties for the term of the life of the property and as this sum is not dependent upon the vicissitudes of mining the discount is properly at the going value of money in most cases not exceeding 6 per cent.

In the case of lands operated by the fee owners the value as of Mar. 1, 1913, should properly be calculated as the present value of the profits year by year to exhaustion. Unfortunately it is essentially impracticable to determine such a value as the profits are a widely varying quantity and impossible to forecast

COST OF PRODUCTION OF "INDIVIDUAL" COAL, DECEMBER, 1917, TO MAY, 1918, INCLUSIVE

far into the future. We would suggest substituting for the profits the present normal royalty value of the property, as indicated by recent leases of similar lands, and determining the present value on the same basis as royalty coal. In this case the question of profits is minimized and it would seem that the discount rate might properly be taken at 6 per cent., leaving excess earnings to take care of the mining risk. As in the case of a sale which would fix the depletion charge, the purchaser would expect to be able to earn more than 6 per cent. on any investment involving a mining hazard, and a 6 per cent. discount based on royalty values would probably fairly represent a fair sale value.

In determining the probable life of a property consideration should be given to its past history as to output, its state of development, probable future output with normal conditions, and to the quantity of coal available on the property or property tributary to its development. As the present value of an annuity for 50 years is within 5 per cent. of the present value of a perpetual annuity, it is probably wise to limit the present value of a property to the present value of the probable out-

TABLE IV. PRICES FIXED BY THE PRESIDENT, AUG. 23, 1917

	White Ash		Red Ash		Lykens Valley	
	Company	Independent	Company	Independent	Company	Independent
Broken	$4 55	$5 30	$4 75	$5 50	$5 00	$5.75
Egg	4 45	5 20	4.65	5 40	4 90	5.65
Stove	4 70	5 45	4 90	5 65	5 30	6 05
Chestnut	4 80	5 55	4 90	5 65	5 30	6 05
Pea	4 00	4 75	4 10	4 85	4 35	5 10

put of say 50 years, regardless of the total tonnage or life of the property.

Acreage which is not estimated to be mined within the 50-year period should be carried in an investment account not subject to depletion and, when opened, treated as a new property.

The present value of property with less than the maximum life above indicated should be based on its probable life resulting, of course, in a higher depletion charge for short-lived properties.

As an example, the present value per ton assuming regular output to exhaustion would be for 10 years' life 74 per cent. of the royalty rate, for 25 years 51 per cent., and for 50 years, 31½ per cent., the suggested limit.

Then, assuming 50 years' reserves and 25c. per ton royalty rate, the present value would be 7.9c. per ton, and with a 10c. royalty rate but 3.15c., while with a rate of 40c., a fair present average anthracite

TABLE V. FIXED PRICES, DEC. 31, 1918

	White Ash		Red Ash		Lykens Valley	
	Company	Independent	Company	Independent	Company	Independent
Broken	$5.95	$6.70	$6.15	$6.90	$6.40	$7.15
Egg	5.85	6.60	6.05	6.80	6.30	7.05
Stove	6.10	6.85	6.30	7.05	6.70	7.45
Chestnut	6.20	6.95	6.30	7.05	6.70	7.45
Pea	4.80	5.55	4.90	5.75	5.15	5.90

royalty rate, the present value per ton would be 12.6c. per ton for a fair average for depletion where reserves are at least equal to 50 years' probable mining and increasing to 20.4c. for 25 years' reserves.

Depletion and Capital Charges—In general, it is our opinion that all plant and all opening and development charges less the value of coal produced during this period up to the time when the mine is sufficiently opened and developed to be able to maintain a normal

TABLE VI. AVERAGE COST, DECEMBER, 1917, TO MAY, 1918

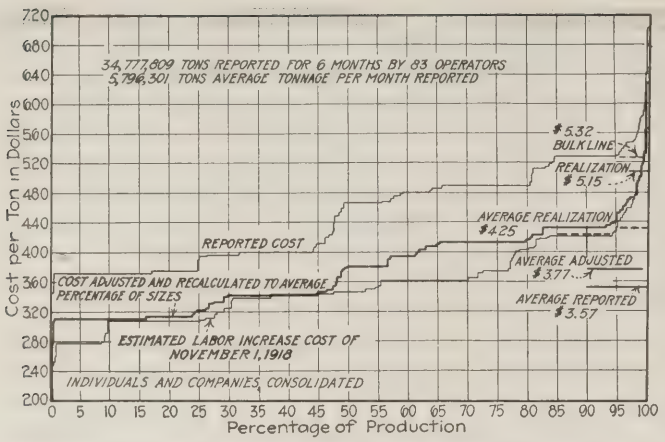
	Fresh Mined Coal, 35,256,550 Tons Cost per Ton	Washery Operations, 3,431,916 Tons Cost per Ton	Total Including Washeries, 38,688,466 Tons Cost per Ton
Labor	$2.593	$0.687	$2.423
Supplies	.616	.260	.584
Transportation, mine to breaker	.004	.007	.004
Royalty, current	.153	.102	.148
Royalty, advance	.002		.002
Depletion	.099	.077	.097
Amortization of cost of leasehold	.014	.024	.016
Depreciation	.091	.086	.090
Pro rata suspended cost of stripping	.023		.021
Contract stripping and loading	.009		.009
Taxes, local	.054	.034	.052
Insurance, current	.016	.014	.016
Insurance, liability	.058	.018	.055
Officers' salaries and expenses	.030	.019	.029
Office salaries and expenses	.048	.024	.045
Legal expenses	.005	.003	.005
Miscellaneous	.026	.023	.026
Total	$3.841	$1.378	$3.622
Increase over May to November, 1917	$0.764	$0.365	$0.719

production should be charged to capital and be subject to depreciation, and all charges for extensions including plant and development work necessary to maintain capacity should be charged to operating expense.

In the case of new development or plant designed to increase capacity or to materially reduce operating expense, a new development account should be opened and the cost of providing such increased output be charged to capital account.

The depreciation account should be so arranged as to extinguish the capital charge against any item of plant or development when such item is either worn out or ceases to be useful to the operation, and it might be well to classify into groups the various divisions of capital charges assigning to each group its probable average life and proper depreciation charge.

Repairs and renewals of parts should be charged to operation, but the life of plant should be figured considering such repairs and minor replacements. For instance, repairs and renewals in a breaker either to machinery or structure should be charged to operating expenses, but on its extension or replacement by a new structure the excess value considering depreciation of the new structure over the old which it replaces should



COST OF PRODUCTION OF BOTH "COMPANY" AND INDIVIDUAL COAL, DECEMBER, 1917, TO MAY, 1918, INCLUSIVE

be capitalized. Similarly, the retimbering of a shaft or main tunnel should be charged to operating cost.

The original capital charge against any improvement should be depreciated so as to be wiped off the books on its abandonment whether due to age and deterioration, to lack of further usefulness due to the exhaustion or abandonment of the mine, the expiration of the leasehold, or to other causes.

Extraordinary Expense Account—Large items of expense properly belonging in operating cost but which would so affect monthly costs as to invalidate comparisons may be put into an extraordinary expense account and this distributed annually into the operating expenses.

Insurance and Taxes—Fire insurance and workmen's compensation should be pro-rated with the monthly costs as should local taxes. An insurance fund should also be maintained to provide against mining accidents such as fires, explosions, irruptions of large bodies of water with resulting flooding, extensive squeezes and such like accidents which cannot properly be absorbed into operating expense.

PRODUCTION OF ANTHRACITE, INCLUDING BANK COAL, FROM DECEMBER, 1917, TO MAY, 1918, INCLUSIVE

Income and excess profits taxes are chargeable against profits and are not proper items of operating expense.

Stripping Costs—The cost of stripping overburden should be kept in a suspense account and charged against the coal as produced. This requires a reasonably accurate estimate of the coal to be produced by stripping made from proper borings or in the case of worked-over areas, from mine data, and as such an estimate is an essential preliminary to any properly conducted stripping operation, there should be no difficulties in properly handling this account.

General—It should be understood that the foregoing accounting suggestions are the personal opinions of the author and have not been approved by any Government department.

Conclusion—The anthracite cost investigation supplements the bituminous price fixing previously described and shows, probably for the first time, the actual range of anthracite costs. The entire work is based on the costs reported to the Federal Trade Commission by the anthracite operators. The analysis and study was made by the Engineers Committee of the United States Fuel Administration, Cyrus Garnsey, Jr., J. H. Allport and myself, with the able assistance of Capt. R. H. Vorfelt, U. S. A., detailed temporarily to the Fuel Administration as Director of Investigation.

Cause of Flare-Up Undiscovered

Chief of Department of Mines and His Assistants Trying to Ascertain What Was Responsible for Recent Catastrophe in Baltimore Tunnel

As usual with accidents in the mines it is extremely hard to find the actual cause of the Baltimore tunnel disaster. Seward E. Button, the chief of the department of mines, with six state mine inspectors, two members of the United States Bureau of Mines and several company officers are trying to ascertain exactly what ignited the powder—a current of electricity or a miner's lamp or whatever else. The number of men killed now stands at 95. The inquiry has been delayed because of the condition of certain of the witnesses who were unable to attend the inquiry and give testimony.

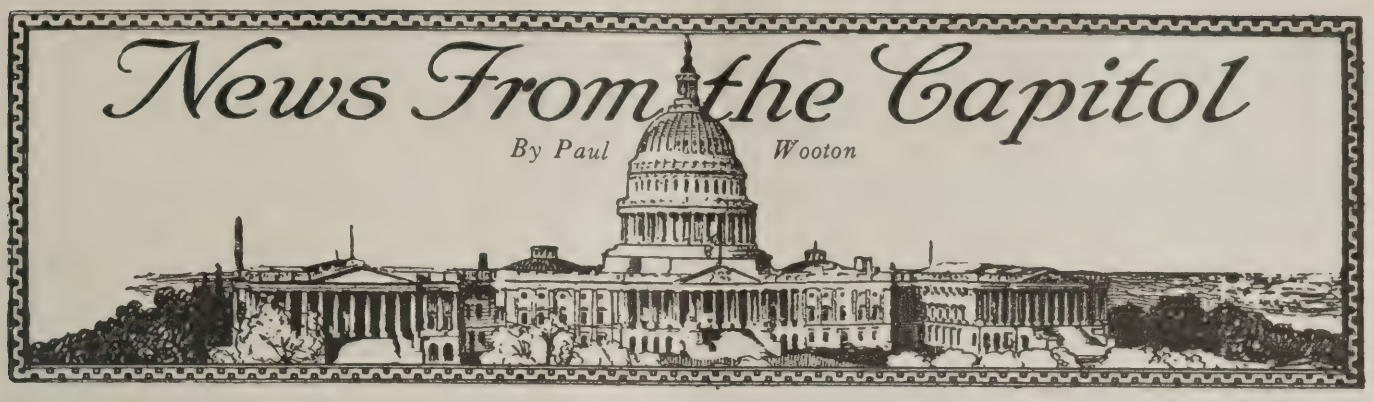
The chief of the department of mines gives four possible causes of the disaster. (1) That a bar carried by one of the men in the car where the flare-up first occurred touched the feed wire. (2) That a keg of powder touched the wire. (3) That as pipes were found in the cars, and lighted tobacco, and as the men had lighted lamps, the powder may have been ignited by some such sort of flame. (4) That as an electric feed wire fell on the rail 2500 ft. inside the mouth of the tunnel, the current may have come back through the cars and ignited the powder. Mr. Button states that for the first three conclusions there is a lack of evidence, but, of course, a lack of evidence does not prevent a thing from being true. The chief seemed, at least at one time, to favor the hypothesis that the flare-up was consequent on the fall of the electric feed wire.

ENTRANCE TO MINE WHERE FLARE-UP OCCURRED
Accident was 150 ft. inside of entrance

The inspector arranged to drop the wire at the point at which it fell in the accident of June 5. It was allowed to drop on two rails though it fell on but one when the fatal ignition occurred. A 13-car trip was put in the same position as on the morning of the accident. A keg of powder was placed in the fourth car from the rear and the current was turned on. No explosion or ignition occurred, nor did anything happen when the keg was placed in contact with iron bolts or even rested on the drawbar of the car. The failure to explode or ignite the powder in the keg made the inspector doubtful of the fallen-wire theory.

He Wanted to Be There

Some years ago a foreman's word was law. This petty official ruled with an iron hand, and there was no "comeback." An inside driver once asked his boss if he could get off on the first of the month, which was then about two weeks away.



The answer was a short, "No!"

The driver made no comment, but in another week again asked the boss if he could be off on the first of the month.

This time the answer was the same as before, only a little louder. The driver walked away and the boss, being a curious man, called after him and wanted to know what the h—l he wanted to be off for.

"Well," answered the driver, "you see, I'm going to get married then, and I just sort of wanted to be there."

In a section of West Virginia it is said the mine cars were so large that they were often run over the Norfolk & Western R.R. The coal company got to making them so big that the railroad company protested, alleging that they couldn't get them through the tunnels. All of which sounds like the sarcastic remark of an operator in a field where owing to the thin coal and poor roof a large car cannot be used.

Senator Smoot Advocates That Government Own Coal and Oil Lands

"We must have either leasing or ownership," said Senator Smoot in introducing his oil and coal land leasing bill. "My bill provides only for the leasing of these lands from the Government." Senator Smoot long has been an advocate of permanent Government ownership of Government coal and oil lands. He was an important factor in defeating the last leasing bill when it was about to become a law on account of the fact that it allowed the sale of coal lands. Under the provisions of Senator Smoot's bill, 50 per cent. of all money received under the measure is to be paid to the state in which the land is located. The money must be used, however, for the construction and maintenance of roads and for schools.

Proposes a Government Coal-Inspection System Through Bureau of Mines

Legislation providing for Government fuel inspection will be introduced in both the Senate and House in the near future. The bill will direct the Secretary of the Interior to establish through the Bureau of Mines a fuel inspection system and will carry an appropriation of $600,000 for that purpose. The action is being taken by a group of legislators because demands have been made on them for some form of coal inspection that will at once assure to the consumer a grade of coal which he pays for, protect the interests of those preparing clean coal, and without discouraging the mining of poorer grades of coal, will exert an influence toward good coal preparation, especially in time of coal shortage.

The proposed coal-inspection system contemplates as a salient feature public advice as to the quality of coal as shipped. The force depended upon to produce results is a public statement of the facts. For this purpose the machinery for accurate sampling of full carload lots is necessary. The Government now possesses facilities for analyses and publication.

It is proposed that each mining company set its own standard of quality, consistent with the particular seam, preparation and market which the business affords, and that the Government shall publish such standard and certify as to whether such standard is being maintained by the mining companies. Such work would not replace inspection by the mining companies. It would not certify as to the quality of each and every shipment, but it would inspect and sample at irregular intervals a sufficient number of cars of coal as shipped to indicate whether the declared standard of the mining company was being maintained.

Mines entering the system would be privileged to advertise that their product was from a mine whose standard of preparation was certified to by the Government. In case coal shipments were sub-standard the mine would be advised of the fact. If the condition continued, the facts would be given publicity and the mine, to retain a place as a certified mine, would be required to declare a new and different standard and one which its product could meet.

Mines entering this system would agree to allow shipments to be sampled enroute at sampling stations and stand any added expense of transportation and handling incident thereto. All analyses would be published from time to time giving accurate information about American coals. Mines need not come into this system, but there would be manifest advantages in being on a Government approved list which would gradually increase the number using the service.

Important Results of Cleveland Coal Convention Summarized

George H. Cushing, the managing director of the American Wholesale Coal Association, sums up the more important results of the Cleveland convention as follows: "The determination of the association to limit its membership to those who are willing to maintain the highest moral standard in their business dealing. The adoption of a platform. The determination to fight for the reinstatement of civil laws relative to reconsignment and demurrage. The determined stand against government ownership or detailed supervision of coal. The stand for the return of the railroads to private ownership, stripped of coal connections. The adoption of local self-government of the Wholesale Coal Association by having each district nominate and elect its own directors."

The employees of the Bureau of Statistics of the Fuel Administration have presented C. E. Lesher, the chief of the Bureau, and Taylor Thom, Jr., the chief of the planning section, with watches as tribute of their appreciation and esteem.

Joint rail and water rates on coal from Birmingham to tidewater by way of the Government barge line on the Warrior River, have been announced. Equipment for regular service has been provided, and coal already is moving from the Alabama fields to Mobile and New Orleans by the water route.

EDITORIALS

Impermanence of Bench Marks

ENGINEERS like to shut their eyes to the impermanence of bench marks, but it is a fact nevertheless that these monuments are not to be relied on for any great length of time. Especially are those below ground subject to change. When the coal sinks, as it does, into the clay, and the clay is heaved between pillars, there is no certainty in the levels of points in the floor or in the ribs.

When the point is in the roof conditions are but little better, for settling coal involves a sinking roof. Then, again, the drawslate in which the plug too often has to be driven is apt to sag and change the level or—a small error—the plug expands and either pushes itself downward with a purchase on the point or is wedged downward in its attempt to relieve pressure on the sides. Where the plug is not driven so hard as to fathom the bottom of hole the swelling plug is not likely to be forced out by its increase in length. However, a plug thus imperfectly driven is likely to be hammered further in by some zealous trapper-boy or miner. Moreover, when the hole is not tapered the plug is not likely to work out by a diametral expansion. As a rule, as holes are drilled and not cut with a pick so there is no taper and the plug remains in place.

As stated, the worst trouble underground with level plugs driven in the roof arises from a general subsidence. Suppose a point inside the mine is found on leveling to be of the same elevation as a point at the entrance to the mine. Grant then that the latter point descends 6 in. before the next extension of levels occurs, and in the extension that the levelman finds another point in the mine at the same level as the point just mentioned. The level of this second mine point would be recorded as the same as the point at the mine entrance, though it would really be 6 in. lower. Similarly, every extension would increase the recorded elevation of points within the mine. A truly level mine would thus be recorded as having a general gradient downward toward the entrance. After several levelings the mistake would be not only measurable, but even important.

Taking points in the floor the leveler would represent the mine as lower, instead of higher, than it really is; and as movements of the floor are more rapid the error would be greater. Extension of levels from bench marks set in the floor is hopelessly inaccurate, so it should not be considered. The floor will often heave without any roof pressure whatever. Certain constituents in the clay of the mine will expand and arch upward long before the clay will begin to squeeze from under the pillars. This lifting will occur before extension of levels takes place and will consequently vitiate results.

Only roof-points are fitted as bench marks for extensions in levels. The roof-points in entries, if not driven in a drawslate, do not materially change level till the acreage around them is partly mined out. If the extension is made before that time it is likely to be fairly accurate. The levels should always be extended from plugs in such headings as are being driven in the solid away from the larger earth movements.

Points on the surface are subject to subsidence and, if badly chosen, may be wholly inaccurate. These errors will occur whether the bench mark is on a stake or cut in the stump of a tree. In fact, engineers have all too much faith in a stump bench mark which may be affected by mine subsidence, earth movements, frost, growth and wind. The effect of growth has, we believe, never been carefully investigated. An inquiry into that matter might be of value to the industry.

We are rarely entitled to demand an immutable bench mark. Most of us record to hundredths when our base for level extensions is incorrect by tenths and even by whole feet. We are justified, however, for the comparative levels of nearby points are important even when we do not know the true sea level or the relative levels of two points remote from each other. A jump of 25 ft. in a railroad survey in central Pennsylvania would have made transportation on that line impossible, yet the levels of all points in that part of the state thirty years ago were being calculated on a basis of 25 ft. in error.

Standardization of Mining Equipment

THE great economies to be effected through using only standardized equipment around a mine are perhaps not fully appreciated, though there has been a marked tendency in this direction during the past decade. This uniformity should extend beyond the mere procedure of purchasing the same kind of mining machine, pump or other apparatus; it should be an interlocking arrangement so that the weight of the mine locomotive, mine cars and other equipment shall be in correct proportion to the size of the mine rails, frogs and switches.

The necessity for carrying duplicate parts for a number of machines or pieces of apparatus will be a serious factor where there are many different varieties of machines used. Thus, for instance, in a mine using a number of pumps, a certain lot of spare parts that are subject to considerable wear, such as water and steam valves and piston rings, must be kept on hand; and where these pumps are of different types, it will be necessary to multiply this number of spare parts by the number of different makes used; and, in order to reduce the number of parts to the minimum, it is probable that the supply department would not order some parts that it might otherwise do if it was not necessary to obtain such a large number of them. Were these pumps all of the same size and type, a good plan would be to order spare parts sufficient to make one complete pump with the possible exception of some of the major portions, such as the base castings.

It is especially necessary to carry heavy supplies at the more remote mines, where deliveries are liable to be slow. It is obviously poor business judgment to risk a complete shutdown of mine operations because of the lack of $10 or $15 worth of spare parts for some machine.

The stocks on hand in a supply room of big producing companies will vary from $25,000 to $60,000 and sometimes be even larger. The interest on an investment of even $60,000 is sufficient to pay the salary of a high-grade man who might be capable of systematizing and standardizing equipment to such an extent that this could be reduced by fully one-half.

On the other hand, care must be exercised not to carry the duplication of spare parts to extremes, especially on permanent equipment such as large hoisting engines. Developments in mechanical lines in recent years have been rapid, and spare parts on apparatus of this kind may quite possibly become obsolete before put into use.

Measuring Coal by Gold

EVERY man is prone to regard the particular industry in which he is engaged as being basic, fundamental and essential to the well-being of mankind. Thus the farmer asserts that the world is dependent upon him for food. The iron producers in like manner are positive that civilization would come to an abrupt standstill were it not for the steady production of ferrous metals and alloys. And so on *ad infinitum*.

Most nations of the world are on a gold monetary standard. Ever since commercial transactions passed beyond the art of barter, the yellow metal has been the yardstick by which the value of commodities has been measured. Its production has been an attractive calling ever since man emerged from the Stone Age, or possibly even before.

It is but natural then, in comparing one industry with another, to make the gold production a standard of comparison. It is interesting to thus place the coal output beside that of gold production and see how the one measures up with the other.

During the year 1918, the gold production of the world has been estimated as amounting to $377,300,000; that of the United States was taken by the same authority as being $68,493,500.

Reports of actual coal production and the value thereof in the United States during 1918 are not yet available, and estimates must therefore be employed. It is reasonably certain, however, that these estimates are fairly correct; and it is not believed that actual figures of production when available will vary from them by more than a few per cent.

The estimated bituminous-coal production of the United States during 1918 amounted to roughly 590 million tons. Now, assuming that this was sold at the mine mouth at the average price of $2.30 per ton, which is probably conservative, its value amounted to $1,357,000,000. Adding to this the value of the 99½ million tons more or less of anthracite, or $317,522,181, we have, neglecting the last three figures, $1,674,522,000. Now, dividing this figure by $377,300,000 we get 4.4. Again dividing it by $68,493,500, or the value of the gold production of the United States (including Alaska), we get 24.4.

Thus it is seen that the value of the coal production of the United States is roughly 25 times that of its gold production, or that the coal production of this country is worth on the open market roughly 4½ times as much as all the gold produced from all the mines of all the world. This is a fact that the general public only dimly visualizes because it is so often bitter in buying gold stock and so seldom puts its money into coal securities.

A Bottle with Two Necks

AT NO part of the mine does the air travel so fast as in the mine entrance and main return, whether that entrance or return be a drift mouth, slope or shaft. It is these two points, therefore, that quite largely influence the resistance of the mine to the ventilating current. Further underground the air is split into a multitude of more slowly moving currents, and the friction is accordingly reduced.

The amount of air to be delivered is not allowed in many cases to determine, as it should, the size of the intake and return. This is largely fixed by a consideration of the use of these passages for transit. We seem to imagine that the air will force its way through these orifices if only a fair way is provided beyond.

In the passageways leading to the fan especially, there are often sharp angles. Where the flows from well separated districts return into a common current no attempt is made to prevent a conflict at the mouth of the single and narrow airway which, vastly too small for the service, must carry the air to the fan.

We overlook the fact that the air is provided with such narrow quarters it must be traveling fast and should be guided gently to its destination by well-shaped airways. We can give the air all kinds of harrowing experiences where the speed of travel is relatively slow, but where the air is moving rapidly the stream lines should be straight and undisturbed.

Unfortunately as we approach the surface the roof gets bad, and the exigencies of continued maintenance demand a more carefully protected roadway. Hence we tend to make the roadways narrow and fortify them with timber. The air eddies around in these narrow passages, and the friction is much greater than it would be in passages of the same size and carrying the same current if only the eddying were eliminated. Concreting such roadways by forms or with the cement gun is therefore a good means of increasing the ventilating capacity of the airway and hence of the whole mine; and it serves to prevent the airway, not to speak of the roadway, being blocked by ice in the winter.

It is perhaps unfortunate that we cannot see the air and so realize visually what a waste of energy there is when a ventilating current is churned up by a line of timber-set riffles. But what we do not see and know may hurt us most severely, and it is necessary for us to realize that we will not get efficient ventilation if we trip our air as it enters the mine by a lot of crossbars, legs and laggings and trap it as it leaves the workings by a series of similar resistances. A concreted shaft is not only safe and durable, it is a money saver in ventilation. No piping or cabling which goes lengthwise of the tunnel or shaft resists the air like the transverse timbering by which these airways are quite usually kept open.

Drunken and disgruntled men rail at the capitalistic class. Fortunately, they rail also at other people, including those in their own families. They are therefore by no means popular, and their own selfish actions frequently are the best antidote for the doctrines they espouse. Do the wife, children and neighbors of an inebriate, or even a shiftless doctrinaire, believe that all the evil in society rests with the men who provide that inebriate or doctrinaire with what little work he is willing to do and what little pay he is industrious enough to earn? For our part, we think not.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

Up to the end of March of this year, according to the reports of the Immigration Service, no great exodus of foreigners had taken place. In the month of the armistice, 4530 more aliens came to the United States than departed, but during the month of February the alien departures outnumbered the alien arrivals by 424. In March the difference had risen to 2014, the number of those returning, by this figure, exceeding the number of those arriving.

In brief, the number of aliens arriving from the beginning of the month of the armistice to the end of the month of March exceeded the number of those returning by 7655. But the arrivals are mostly of the commercial classes and the exodus is of laboring men and is evidently gaining in strength as the months pass. It would be much larger if there were more accommodation. According to the *Nautical Gazette*, the bulk of these aliens seeking traveling accommodation are Southern Europeans — Portuguese, Spaniards, Italians and Greeks, with some Poles and Bohemians.

HOWE SAYS ABOUT FOUR MILLION WILL RETURN

Frederick C. Howe, U. S. Commissioner of Immigration at the port of New York, says: "The middle European peoples, especially the Poles, are going back for nationalistic reasons; the Bohemians the same. The Russians and Hungarians think that land is going to be very cheap over there. They have heard that the land in Russia and Hungary has been nationalized, and it is expected that it will be nationalized in Germany and Austria, too.

"I estimate—it is just an estimate—that a minimum of 4,000,000 people will probably go back to Europe just as soon as they can get transportation. Sometimes I am inclined to think that the number will be greater. Many Austrians, Hungarians and Russians, and to some extent Scandinavians, are going back because they feel they are not wanted here. They feel that America is hostile to them. I have heard that deportation clubs have been organized among these people, but I don't know whether it is true."

In the five months, November and December, 1913, and January, February and March, 1914, the United States received 261,595 more aliens than it lost. The same five months in 1918 and 1919, as stated, showed an increase of 7655. The difference shows how we have failed for a long time to obtain our former supplies of man power.

EMIGRANTS CAN'T GET BEYOND NEW YORK CITY

The working men are moving toward the ports but they find it difficult to secure transportation, and it is this fact that is delaying their exit. With an easing in transportation facilities the movement will be more rapid and laboring men will become more scarce. Thus when exporting becomes possible, the men to make the material to be exported become lacking. But after all, as far as coal is concerned, the problem of exports will be, not so much lack of men and hence of coal, though both may be grievously short, but lack of a sufficiently low schedule of shipping rates to make coal shipments feasible.

The mine workers of the West End Coal Co., Nanticoke, Penn., are on strike because the company refuses to adjust certain grievances of the men. The way to rectify matters of the kind is through the conciliation board of the region, after the local representatives of the mine workers and operators have failed to agree, but the 1500 men at this colliery will not have it that way; they have said what they want and will have it whether in accord with their agreement or not.

On June 2 the mine workers at the Creighton coal mine in Allegheny County, Pennsylvania, went on strike to compel a recognition of the union. Another mine in the same district has gone on strike and for the same reason. There are about 500 men idle in consequence. Five men were riding an electric locomotive on a trestle that spanned a deep ravine at the plant of the Creighton Coal Co. (which trestle joined two mine openings) when a shot from a man in ambush killed Andy Loobek of Tarentum. Another shot passed through the hat of a second man. Three other shots were fired, but the underbrush was so thick that the assassin could not be seen. It is thought that he is a negro, for one was seen recently with a rifle near the mine.

The Canadian royal commission on industrial relations held its Sydney, N. S., session on June 6, taking testimony from 13 persons. F. W. Way said the men were extremely discontented with what he termed the low wages, long hours, high prices, opposition to collective bargaining and inadequate housing which the mine workers of the province have to face. He stated that the lowest wage paid was $3 for a 12-hour day and that wages were from 25 to 30 per cent. lower than in Western Canada.

The lowest wage in the mine he declared was $2.90 per day. He added that men are now employed 11 to 13 hours daily and that every second week they work a 24-hour shift with the result that they break down physically and morally. Sixty per cent. of the men work on a 12-hour shift and the shortest workday is 10½ hours. He declared that the families of the men employed by the Nova Scotia Steel and Coal Co. were living in houses of from three to five rooms for which they were paying $5 to $6 per month. They were willing to pay more money, even double the rent, for better accommodation.

DOMINION COMPANY'S LOWEST PAY, 30C. AN HOUR

General Superintendent Rice of the Dominion Steel Corporation said the lowest price paid was 30c. per hour. The company was unable to put on three shifts of 8 hours, because it would add 30 to 50 per cent. to the cost of production. Rents have not been increased for several years except in the better class of houses. Of the houses of the Dominion company 120 are renting for $4 per month.

A. J. Tonge said that the minimum wage is $3.11 for an 8-hour day and that the average daily wage is $4, although contract men get as much as $50 per week. Coal at the bankhead cost more than double what it did in 1914.

In France a strike of the Federation of Miners took place on June 16. It seems to involve all the mine workers of that country. The general secretary of the federation said that the proposals made by M. Colliard, Minister of Labor, and M. Loucheur, Minister of Reconstruction, were unsatisfactory. The men want an eight-hour day to include the time when they are being lowered into the mine and hoisted to the surface—two periods of about 20 min. each—and also a meal time averaging 30 min. The time of actual service would be reduced to 6 hours and 50 min. The Government supported the demand in general but would not accept the specific statement of June 10 which read "Eight hours, including meal time, to be counted from the time the first man goes down till the time the last man comes up."

The Governmental authorities apparently thought the men would come out as they went in the mine and the loss of time in reaching their work would be only 20 min. They demurred when they found out that the men would start work together and quit work together and have to wait at the shaft mouth, morning and night, making the loss of time 40 min. for hoisting and 30 min. for lunch or three hours and 30 min. per day of three shifts. The mine workers voted at their Marseilles convention 373 to 120 to demand the execution of the contract as presented.

DISCUSSION BY READERS

EDITED BY JAMES T. BEARD

Remarkable Pressure Chart

Letter No. 1—That is certainly a remarkable chart shown in *Coal Age*, Apr. 17, p. 728, and it is no wonder that W. F. Harry is asking for the opinions of others regarding it. As stated in the editorial reply, the chart is not a true representation, there being at least three inconsistencies, as I view the matter.

In the first place, it is only reasonable to assume that the load carried by this power station was a fairly uniform one, from the indications of the pressure line during the day. But, even with a uniformly constant load, there would appear to be no reason why the chart should show the straight line indicated for the nightshift, from the statements of the nightman.

In reply to this inquiry, the editor suggests that the chart was spiked. That may be the case or the night fireman, if so disposed, could turn the chart around at the beginning of his shift, or when it showed a good pressure in the boiler, and having done this remove the chart from the gage and replace it again at the close of the shift.

If this was done, as I have described, the nightman could bank his fires and allow the steam to go down, by that means saving the 30 per cent. of coal during his shift. The saving of this amount of coal is the second inconsistency to which I have referred. Such a saving is incredible. Unless the nightman is an exceptionally good fireman and the daymen both very extravagant in their methods of firing, it would be impossible to show this difference in the amount of coal burned. Indeed, it is my opinion that such a difference could not exist under normal conditions, in the average run of firemen.

Offer To Increase Plant Efficiency Declined

This reminds me, however, of a little incident in my own experience. Having observed some of the extravagant practices and the losses resulting therefrom in a certain plant where power was being generated, I submitted a proposition to the management to make a few changes in the arrangement and accept as my pay the saving in coal that resulted from the proposed changes. The offer was a good one from my own and from the operator's standpoints, respectively, but it was declined, as many such offers are, through indifference or ignorance, as the case might be.

The third inconsistency, regarding this chart and the claims made, has reference to the statement that the fires were cleaned three times during the nightshift of 10 hours. To clean the fires three times in a single shift is much out of the ordinary, in the usual practice of firing. Furthermore, everyone who has fired a boiler knows that more coal is needed when a fire must be cleaned, as some of the unburned coal will pass through the grate and be lost in the ashpit, while the furnace and boiler will be cooled by the inrush of air through the firedoors.

This claim of cleaning the fire three times makes all the more unreasonable the statement that 30 per cent. of the coal was saved during that shift. Again, the necessity of cleaning fires so frequently would indicate that the load carried was much greater at night than during the day, which does not conform to the showing of the chart for that shift.

In closing, permit me to suggest that Mr. Harry should give the day fireman another job, for a week, and let his efficient nightman take the dayshift. Then lock the gage and attend to replacing the chart himself. Having done this, it would be interesting to learn what results the nightman would be able to show when working on the dayshift. S. D. HAINLEY.

Osceola Mills, Penn.

A Modified Longwall System

Letter No. 3—Referring to the letter of W. H. Luxton, *Coal Age*, Apr. 24, p. 764, permit me to draw attention to two statements in his closing paragraph. First, he suggests that "The depth of cover should not be less than 200 ft. to obtain the best results in longwall working." He follows this with the statement that "The principles involved in this method are those that must ultimately be applied to work such seams."

It would certainly be of interest to know if Mr. Luxton has ever had any practical experience in working longwall under a light cover, which induces him to make the suggestion that the success of this method depends on a depth of cover not less than 200 ft. in thickness. In the article that started this discussion, Apr. 27, p. 395, F. A. Pocock states that the cover of the seam, in the method he has proposed, is only 80 ft. in thickness. Now, from Mr. Luxton's point of view, the longwall method of mining could not be successfully applied in that case.

It would seem only fair to Mr. Pocock to ask that others who have had experience in working the longwall system under a light cover should favor us with their opinions in regard to applying this method of mining to shallow seams. It is for the purpose of inviting the expression of opinion on this matter that I have asked the privilege of sending a second letter on this subject, which is one that has always been of interest to me.

Longwall Possible Under Shallow Cover

Personally, I have no hesitation in stating that there is, to my mind, no reason why the longwall method of mining cannot be successfully applied under the 80-ft. of cover mentioned in Mr. Pocock's article, provided only that the strata overlying the coal is such as will make a good roof for the purpose. I could cite instances where hundreds of acres of 3-ft. coal have been worked successfully on the longwall system, and the cover, in some places, did not exceed 60 ft. in depth, while the thickness of the coal varied from 20 in. to 5½ ft.

Allow me to cite just one important illustration, regarding the applicability of the longwall method of mining to a far more difficult problem than that presented by Mr. Pocock. It has reference to the working

of the Pittsburgh seam, with which most *Coal Age* readers are thoroughly familiar, but which they are prone to regard as not being adapted to longwall work. Let me say, here, that I have demonstrated the falsity of this conclusion and can only attribute it to their lack of experience in longwall methods, which is sure to result in failure. Success in longwall requires a thorough experience and training in that work.

My reference to the working of the Pittsburgh seam by longwall relates to an instance where the thickness of the seam varies from 3 ft. 6 in. to 5 ft., the coal being overlaid with 1 ft. of slate, above which was 3 ft. 6 in. of "rooster coal." The seam was worked successfully on the advancing system of longwall.

Allow me to add that the work was carried forward in a proper and systematic manner. Mr. Pocock's proposition appeals to me as one that can only be worked successfully by the longwall method that he has proposed and which promises to produce a quick output and has due regard for the future life of the mine.

McKeesport, Penn. ANDREW ORR BAIN.

Safe Handling of Explosives

Letter No. 1—The reading of the "Safety Letter" of the Consolidation Coal Co. sent to its safety committee and which appeared in *Coal Age*, May 8, p. 874, reminded me of a sad incident that befell a miner by reason of which he is now bowed down in grief and sorrow, as the result of his own negligence in the use of explosives.

Returning home one morning after working an all-night shift in the mine, the man brought with him a quantity of gelatin dynamite that had become frozen. Placing the explosive in the oven of the stove in the kitchen of his home, for the purpose of thawing out the frozen dynamite, the miner went outside to do a few chores, which was his regular custom. He stayed a little longer than he had expected and when about to return was started by the loud report of an explosion in the house, one side of which he beheld blown to atoms.

The explosion killed his wife and three-year old daughter who were both in the kitchen at the time. The title of the safety letter to which I referred is "Leave Your Explosives Outside." Had this man obeyed that injunction and not taken the explosive into his house, he would not now be suffering from the sad recollections that fill his mind, today.

Estimating Charges Fired Per Lives Lost

When one thinks of the tremendous quantity of explosives that are being used today, in the mining of coal, it is astonishing that the number of accidents from this source are so few. In the anthracite region, where the coal is blasted off the solid, it is nothing unusual for a miner to use 25 lb. of powder, in the performance of a single day's work. Assuming the average charge of powder placed in a hole is from 2 to 3 lb., it would appear that an anthracite miner would fire from eight to nine shots, in a single shift.

Now, if there are 50,000 men employed in the anthracite mines, cutting and blasting coal, and each man prepares an average of eight shots, the total number of charges prepared in a single day would be $8 \times 50{,}000 = 400{,}000$; or in a single year of 260 working days there would be a grand total of $260 \times 400{,}000 = 104{,}000{,}000$ charges prepared for blasting.

But, it is estimated that out of the 550 fatal accidents occurring yearly in our anthracite mines, 14 per cent. of these are due to the use and handling of explosives. This makes the total number of fatal accidents due to explosives $0.14 \times 550 = 77$ lives. It is thus perceived that the number of charges fired, per life lost, is $104{,}000{,}000 \div 77 = 1{,}350{,}650$ charges, nearly.

It is true, as has been stated before in *Coal Age*, that it is not the inexperienced but the experienced miner who is the most frequently hurt. The experienced miner has, through long years of practice, grown careless in the handling of explosives. The more often one performs a dangerous task and the more he handles explosives, the more careless he becomes. Not long ago I overheard the remark of an artillery instructor who said that he could always depend more on a green recruit than on an old soldier, in the handling of explosives or moving them from one place to another.

Common Causes of Mine Accidents

Allow me, to give the following common causes of accidents that occur in the use and handling of explosives:

1. A miner bites off the end of a squib, or dips the match in oil, or cuts too short a length of fuse to quicken the explosion of the charge that he has prepared, and the shot goes off before the miner reaches a place of safety.
2. A miner returns to his place too quickly, on the failure of a shot to explode in the usual time, and is caught and killed by the delayed blast, which was a hangfire.
3. A miner attempts to withdraw a charge that has failed to explode and an explosion follows and kills him.
4. A miner prepares a charge, with his lamp in his cap on his head, and the result is that a spark falls from the lamp into his powder can and the fellow is badly burned or killed.
5. Carrying explosives unprotected on one's person or leaving it in niches in the rib or on the timbers supporting the roof.
6. Tamping a shot with a steel or iron bar.
7. Crimping a detonating cap with the teeth, instead of using pliers designed for that purpose.
8. Not properly adjusting the cap or detonator in a cartridge.
9. Using an inferior quality of explosive or mixing different explosives in the same charge.
10. Attempting to thaw explosives when frozen.

The right and wrong methods of inserting a cap in a primer were explained in the discussion "Priming a Cartridge," *Coal Age*, Vol. 14, p. 327 and I will not repeat the operation here. In spite of the state mine law prohibiting many dangerous practices in the use and handling of explosives, miners still persist in taking chances and violating the law. An instance of this was the fatal accident that occurred in the Baltimore No. 2 tunnel of the Hudson Coal Co., at Wilkes-Barre, Penn., a few days ago (June 5), in which nearly a hundred men lost their lives.

It is reported that about 150 men were being hauled into the mine on a special trip of cars and, in violation of what should be the law in every mining state in the Union, the men took seven kegs of powder into the cars with them. The explosion that took place, whether caused by the breaking of the trolley wire or a miner's lamp or otherwise, filled the entry with flame, burning and killing the men.

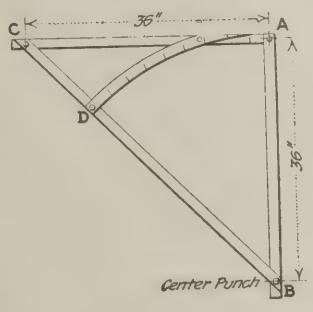
Obey the Laws and Avoid Many Accidents

To avoid these fatal accidents, the miners must cease to violate the laws made for their protection. Many miners seem to think that these laws are made in the interests of their employers and they are often indifferent to them. It is up to the mine officials and mine inspectors to teach them that this is not the case. Every violation of the law whether resulting fatally or otherwise should be suitably punished. There is no industry where care and constant vigilance is more needed than in coal mining.

Seldom does a miner feel his own responsibility for the safety of himself and his fellow-workers. If the fireboss reports his place safe in the morning when he goes to work, the miner takes it for granted that it is safe throughout the day and gives little heed to any danger that may develop. Every practical miner should know that the condition of his place, in respect to safety, may be greatly changed after the first shot is fired, and care is needed to avoid danger.

Before closing, kindly allow me to give the following brief don'ts, which every miner should keep in mind:

1. Don't go to a powder house with a naked light or a lighted pipe or cigarette.
2. Don't carry powder on your shoulder when stepping on the cage to go down the shaft or when traveling an entry where trolley wires are hung.
3. Don't ride in cars carrying explosives.
4. Don't carry explosives about your person or send a laborer to bring them but go yourself.
5. Don't open your box to start to make up a charge of powder until you have first placed your lamp at a safe distance away from the box in the direction in which the air is passing, and don't smoke a pipe or cigarette when preparing a charge or handling an explosive.
6. Don't shorten the match of a squib, or dip it in oil, or cut too short a length of fuse in blasting.
7. Don't crimp a cap with your teeth, in order to make it fast on the fuse, but use the pliers for that purpose.
8. Don't tamp a hole with a steel or an iron bar, but use a wooden tamping rod, which can be gotten at the powder house.
9. Don't fail to keep your box in a safe place away from the track and don't sit on the box with your lamp when smoking.
10. Don't return to a shot that has failed to explode, or proceed to examine a blast until the smoke has cleared away after the explosion, and don't use two kinds of powder in the same hole, or attempt to withdraw a misfire.



These and many other don'ts that might be mentioned, if obeyed, will save many lives.

West Pittston, Penn. RICHARD BOWEN.

Turning Rooms Without Sights

Letter No. 3—I have been interested in the several references and suggestions made recently, in regard to turning an angle where no instrument is available, as when a room is to be turned off an entry and there is no sight given to determine its direction. One suggestion is that given by Ostel Bullock, *Coal Age*, Feb. 13, p. 306, which was followed by another, by a gas inspector of Worley, Ky., in the issue, Apr. 24, p. 742.

Kindly allow me to describe a triangle that I have found useful for this purpose and which can be readily made by almost any handy mine blacksmith, with a little assistance from an engineer. The scheme is shown in the accompanying diagram and consists of a right triangle made of bar or strap iron. As shown in the figure, there is riveted to this triangle the arc of a circle graduated every 5 deg. from 0 to 45 degrees.

The device is readily constructed by taking a flat, iron bar $\frac{3}{8}$ by $1\frac{1}{2}$ in., in section, and 6 ft. 4 in. long, cutting it in the center and welding the two ends together to form a right angle, and drawing out the corner until it is a perfect square as shown at *A*. To complete the triangle the cross-brace *BC* is riveted at *C* and secured at *B* by a $\frac{3}{8}$ x 1-in. capscrew, with a center punch made in the head to form a sight.

An engineer should then mark off the arc of a circle, on a radius of 36 in. A few nails set firmly in a board will enable the blacksmith to bend a piece of strap iron sufficiently close to the arc to serve the purpose intended. The arc is then riveted to the triangle, as shown in the figure, and when this has been done a notch is filed in the end of the arc $\frac{3}{4}$ in. from the side of the triangle, so as to correspond to the sight point at *B*. Similar notches are filed in the arc for each five degrees, but this should be done by the engineer, who divides the arc, from *A* to *D*, into nine equal spaces of five degrees each.

The use of this device will need no further explanation than to say the side *BA* is first made to conform with the center line of the entry, and the side *AC* will then indicate the direction of a room driven at right angles to the entry. The graduated arc can be used to deflect any desired angle. IVOR LIVINGSTONE.

Paint Cliff, Ky.

Perils in Reconstruction

Letter No. 9—Reading the several letters that have been written, regarding the work of reconstruction following the war, impresses one with the thought that there is a general feeling of worriment prevailing at the present time and that practical men are devoting much thought and time to the study of the situation.

As everyone knows well, we were not expecting peace any more than we were looking for war at the time it was forced upon us through the encroachments made upon our rights as a nation. During the critical period that followed, it was our patriotism and determination to win that led us to sacrifice everything.

When one considers the spirit of sacrifice and cooperation that was manifest by the people throughout the country at that time, there is a feeling that the same patriotic spirit will continue to triumph over the difficulties presented in the problems that confront us in getting back to normal conditions.

FAIR AND JUST TREATMENT OF LABOR

Of all the problems that have arisen probably the most important is the readjustment of wages in the industrial world. It is natural to feel that some trouble may arise from this source, but the solution is to be found in the honest and fair dealing on the part of both employer and employed.

The war has given a great impetus to the labor movement. The higher wages that have, for a time, been within their reach has given to the large majority of laboring men a desire for better living conditions. This desire that has taken possession of so large a proportion of industrial workers is one that employers must consider. These, indeed, have a new lesson to learn in regard to the treatment of the men they employ.

If perils in reconstruction are to be avoided, labor and capital must each develop a spirit of patriotism and coöperation. A fair day's work must be given for a fair wage that will provide good living conditions for all. Much will depend on mine officials avoiding the treatment of their men as inferiors and slaves, using rough language and discharging them for small offenses.

No one will deny the right of a foreman to discharge a man when such action is necessary to maintain the discipline of the mine. But, when a man is discharged for a trivial offense, it has a tendency to create a feeling of unrest among his fellow workers. It is this restlessness that makes the workers easy marks for the I. W. W. or agitators for Bolshevism.

At present, one thing that creates a feeling of uncertainty in regard to the future is the common belief that

wages will be lowered. The situation is one in which little material is being purchased owing to the fear that prices will come down in a short time. Needed repairs are being held up for the same reason.

When the question of wages and prices of material is definitely settled, all business will reach a more normal basis. What would greatly assist in restoring confidence would be the opening up, by the government, of the long-planned building projects which would give ample employment for our returning soldiers.

———, Ky. PATRIOT.

Quality of Mine Timber

Letter No. 2—Some time ago, I read with much interest a letter that appeared in *Coal Age*, drawing attention to the need of using a good quality of mine timber (Feb. 13, p. 333). This is a subject that mine superintendents and foremen should consider worthy of more attention than it has commonly received at their hands. In this respect, not only the quality of the timber but its size and kind should be regarded.

Too often it happens that a mine is located in a section where timber is plentiful and little thought is given to its proper use until the supply is nearly exhausted. Then the higher officials generally awake to the fact that the company's timber has been wasted and the foreman is quite generally blamed for its misuse.

Where a poor quality of wood is used for timbering mine airways, it will last but a short time and the expense of renewal cuts a big figure in the cost-sheet of the mine. It often happens that this gives rise to bad feeling between the management and the superintendent, foreman or purchasing agent who is responsible for the quality of the timber sent into the mine.

Care Needed in the Purchase of Timber

In order that a mine shall be safely and efficiently timbered, not only must good timbermen be employed, but the one who does the buying must be a practical man fully acquainted with mining conditions and familiar with the qualities of timber. Moreover, he must be furnished with data in respect to the size of the timbers required for different purposes. Contracting for mine timber must include full specifications giving the size, kind and the time of cutting the wood, which should always be done in the winter months when the sap has left the timber and the latter is more readily seasoned for use.

An incident that illustrates the waste of timber that may result from lack of care in the specification of what is needed in the mine, occurred at a place where I was employed not many years ago. It became necessary to timber a particularly weak portion of the haulage road in that mine, and the foreman gave an order for sawed timber to be used for the collar bars. By some mischance the bars when delivered were found to be too short and had to be thrown aside. As the superintendent refused to place another order for sawed timber, it became necessary to cut such timber as could be found on the company's land, which, however, furnished nothing of a suitable quality for mine use.

After many delays and misunderstandings, I received 20 sets of timbers, and was told to place them 4 ft. apart, center to center, which I did. Hardly had I finished placing these 20 sets when it was necessary to start putting in other timbers between them, because it was clear that the timbers already set would not support the roof. There was poplar, beech, elm, birch, and some hickory. Some of it was fairly good, but, owing to the way in which it had been cut, it could not be used efficiently, and the whole job was a failure. Had the timbers been able to support the weight, however, much of it would soon have been covered with fungus growth, in the mine, and would have rotted in a short time.

It is gratifying to know that many of the larger companies operating in this state are now giving the timber question considerable thought. Some of these companies have started to replenish their diminishing timber supplies by setting out new trees. In one or two instances, several hundred acres of land have thus been retimbered in a year. One company has several hundred acres of walnut trees that will be large enough for use as mine props, in a very short time. While the company could sell this timber they realize that the quality of the timber is more important than the profits of its sale.

Observations on Wet and Dry Conditions

My own observation leads me to believe that white-oak timber when cut in the winter months will outlast any hardwood timber if it is used either in a dry place or in a wet place, alone. But if it is subjected alternately to wet and dry conditions it will rot quicker than some other timbers under the same treatment. Elm, I believe, will last longer when it is wet part of the time and then dried, or where the air is moist part of the year and then much drier.

Frequently, much of the annoyance of broken timbers can be avoided by the mine foreman using good judgment in placing timbers of different kinds in parts of the mine where they are best adapted to the conditions. Also, when drawing timbers from worked out areas, much of the broken timber can be used again, for lagging or for short legs set in hitches cut in the coal, and still smaller pieces can be split up for caps.

In drawing pillars in mines, it is necessary to have props of good quality that are able to perform the duty required of them. When soft props are used for this kind of work, they should be tapered somewhat at the bottom so that they will mushroom at the point, instead of being broken by the descending weight. This will permit of their being used again. A proper regard for these precautions will make coal mining not only safer but more economical, by enabling the recovery of a larger amount of pillar coal. I hope we shall hear from others who have had experience in the use of different kinds of timber under different conditions and where the quality of timber has been made a study.

Cleaton, Ky. OSTEL BULLOCK.

Efficiency of Mine Workers

Letter No. 3—Kindly permit me to refer to the question of a six-hour day and a five-day week mentioned in the general labor review that appeared in *Coal Age* a short time since (Apr. 3, p. 629). I wish to draw a brief comparison between conditions in the mine in Great Britain and those in this country, from the standpoint of a miner.

Having worked in the mines in the North of England over 20 years before coming to this country, I should say that the work of mining coal there is far more arduous, owing to the greater depth of the seam and the decreasing height of the coal. Moreover, the mines

in Great Britain are seldom as well ventilated as the coal mines in this country, although I will not say but that the ventilation here could often be much improved.

My opinion is that the work of mining is not as healthy in British mines as here in America and, for that reason, the British miners are more justified in demanding shorter hours than are the miners in this country. I believe, however, that our miners, here, would be satisfied with something less than a 30-hr. week. Nevertheless, it is possible that the proposition would provide a suitable remedy for the present injustice done to a large proportion of mine workers, owing to the closing down of many of the smaller mines, while other mines are working practically full time and, in a few instances, are hardly able then to fill their orders for coal.

Anyone familiar with the situation will agree that coal mining is somewhat of a seasonable occupation, and this is true to a greater extent in this country than in Great Britain. Considered from this angle, the question of a 30-hr. week has another significance quite different from what would apply to the mines in Great Britain. It is unnecessary to argue that equal fairness and justice should be shared by all coal miners in this country. To secure this equality of conditions, the lesser demand for coal in the summer season should be met by a reduction of the number of working hours, rather than by the closing down of those mines that may be less fortunate in the matter of securing orders for their output. The arrangements necessary to effect this distribution of work and accord to every mining district equal fairness and justice may require some provision that would rightly regulate the industry.

The Allotment Law in England

In England, there prevails what is known as the "allotment law." By this law, the town council or the county council, on the receipt of a petition asking for the allotment of certain lands and signed by a sufficient number of voters in the district, grants the said allotment at a certain reasonable rate of compensation or rent, which they are authorized to fix. I believe the scheme has been found fairly satisfactory both to those desiring the allotment and also to the farmers and land owners concerned.

This is only a suggestion of what is done to relieve the distress that may arise in certain districts, during the summer months. The arrangement is far better than compelling operators to pay their miners for a full week when they work but half-time, which would be an injustice to operators. I do not wish to be misunderstood, however, and will say if our miners are to be granted a 30-hr. week during the summer months, let them be paid for the 30 hours of work performed, which would be reasonable and just; only let the distribution of the summer demand for coal be such as to give to every mining district and mine the same opportunity for work.

During the winter, it is my opinion that a working day of 8 hours, counting from the time the miner enters the mine until he again reaches the surface, ought to be considered a reasonable day's work. To make the 30-hr. week apply to the winter as well as the summer would not enable the mines to meet the demand for winter coal, unless a larger number of miners were to be employed during that season, which would mean an overplus of labor in the summer months.

———, Ind. EQUALITY.

Prime Producer in a Coal Mine

Letter No. 2—The question of who is the prime producer in a coal mine, suggested by the inquiry that appeared in *Coal Age*, Apr. 3, p. 637, seems to me should not be restricted to the workers underground, but should be taken to include all who contribute their share in the work of production. My idea is that the coal is not actually produced until it has been placed where it can be utilized; or, in other words, put on the market.

Now, I notice that both the inquirer and the editor replying to this question regard the miner who digs the coal as the actual producer. While there is no question but that a good class of industrious, thrifty and steady miners are a great asset in a coal mine and go far toward insuring a steady production, it must be remembered that when the coal is loaded into the mine cars, or even after it has reached the tipple and is dumped over the screens, it has not been placed where it can be used by the consumer.

The Individual Workers in an Organization Likened to the Spokes in a Wheel

In answering this question, the editor has very properly likened the entire force, engaged in the operation of producing coal, to a wheel having many spokes. He states that one spoke may be missing and the wheel will still perform service. The illustration is an apt one and sets me to thinking as to which of all the workers concerned in producing coal on the market is of the most importance.

Now regarding the question from this point of view, it appears to me that there can be no production, unless the mine is operated continuously; and I want to ask, Who of all the mine workers is the one most largely responsible for keeping things moving in the mine? My answer is, The mine boss or foreman. It is my belief that he is the most important spoke in the wheel.

Not only does the mine foreman perform his own particular duties, in the direction of the work; but it is up to him to determine the relative efficiency of each worker in the mine and, by correlating their work, strengthen every spoke in the wheel. Where he discovers one that is weak he studies how to improve and strengthen the defect, or to replace the weak spoke by a stronger one. Should the foreman become inactive, or allow these defects to escape his attention, the development of the mine and its production will certainly suffer.

The importance of a good foreman is readily observed when one goes into a mine and finds the miners idle for lack of cars to load. There may be some trouble on the haulage road, or in the shaft, which delays the turn that should come regularly to each miner. Everything must stand still until the foreman or one of his assistants finds and removes the trouble and again puts the wheel in motion.

A wise management can easily determine the condition of affairs underground, by a close scrutiny of the development shown on the blueprints of the mine map, and by the amount paid for yardage each month. Under normal conditions of working, this amount should be in proportion to the tonnage produced. For this regular development, which is the index of production, I hold that the mine foreman is most largely responsible and is therefore the "prime producer."

Linton, Ind. W. H. LUXTON.

INQUIRIES OF GENERAL INTEREST

ANSWERED BY JAMES T. BEARD

Outlook in Coal Mining

The fact that many helpful suggestions have appeared in *Coal Age*, from time to time, in the discussion of numerous difficult problems that arise in the operation of coal mines leads me to draw attention to a situation into which it would appear the coal-mining industry is helplessly drifting today, and to ask if there is anything that can be done to avoid the disaster that threatens many mines.

It is well known that, for the past three and four years the extraordinary demand for coal, by reason of the war, has resulted in the opening of a large number of mines throughout the country, many of which are in isolated positions in respect to the transportation of their products to market. Again, in the haste to produce a large output of coal, other mines more favorably located are by no means equipped in a manner to compete with longer established operations in their district and supplying the same market.

The question is, What can be done to insure the future of mines that are thus handicapped at the present time? Now that the war is over, there is not the same demand for coal that there was and which was responsible for bringing to life these new operations. It is not strange, representing as they do capital invested largely in a patriotic spirit at the time of the nation's need, that much uneasiness will continue to prevail, unless a way out of their difficulties can be found that will insure to them a future based on an increase in the industrial life of the country? It would seem that there would be a constantly increasing demand for the exportation of coal from this country owing to the devastation in Europe and the needed work of reconstruction, which is now already under way.

Allow me to ask *Coal Age* and its practical readers who are so largely interested in the welfare of the coal-mining industry, what suggestions they have to offer that will render the present outlook more hopeful. What measures can be adopted generally, in the coal industry of this country, that will afford an intelligent solution to the situation that confronts a large number of our mines?

Observation convinces me that this situation is not exceptional, as affecting but a few isolated operations, but there are a large number of producing mines that have not become sufficiently established in the markets and who are otherwise handicapped by reason of their limited experience in the undertaking in which they embarked at a time when the nation needed their help. Now, that times have changed, these young operations need what support and assistance can be given them by government regulations and the intelligent advice of coal operators longer in the game. OPERATOR.

————————, Ill.

Coal Age is glad to submit this inquiry to the helpful consideration of its readers. The letter is but a sample of others that betray the uneasiness that naturally exists in the minds of a number of coal operators owing to the indefiniteness respecting the future of the coal industry.

It is true that all industries are experiencing a crisis at present. How long this crisis must be endured and what the future has in prospect is necessarily quite uncertain, but there is more reason to be hopeful than to be castdown regarding the outlook. There is every reason to anticipate a great revival of business throughout the industrial world, and coal mining is the chief dependency of that industrial life. These are words of cheer, but none the less true.

The present problem, however, is to bridge the chasm of readjustment that divides the abnormal conditions of the war period and the normal conditions to follow when the wheels of industry are again set in motion, and labor and capital are working in harmonious and satisfied coöperation. In the meantime, let our help be extended to preserve the life of every operation, however simple, believing there will soon be need and a ready market for all production.

Without prejudicing the many good suggestions that will undoubtedly come from our practical readers, in response to this appeal, we would suggest that there is great need at this time that every operation should look well to the efficiency of its organization. Particularly is this true in respect to new undertakings. There is far more to be learned, in regard to the efficient and successful operation of a coal mine than many operators of long and varied experience are willing to believe.

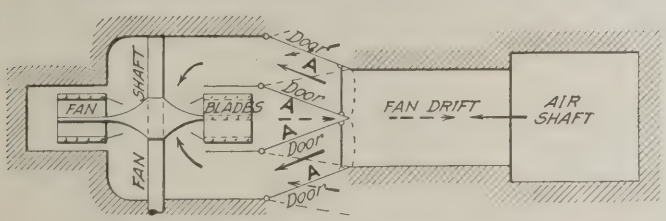
The result of recent investigations of power-plant efficiency, in large corporations, has proved that the stopping of unsuspected leaks in all industries can only be intelligently accomplished by those who have an intimate acquaintance with the science and practice involved in an operation and which must go hand in hand in order to secure the highest efficiency. This fact has been demonstrated in the industrial life and success of many large coal corporations.

The present low rate of production in the bituminous mines of the country, and the fact that consumers are getting rid of the reserve stocks accumulated during the war period, presages a scarcity of fuel this winter that will be every bit as serious as that experienced last year. This will be particularly so if the winter is severe.

Under these circumstances, it is a foregone conclusion that the output of every operating mine will be needed if industry resumes the activity it manifested before the signing of the armistice. The demand for coal will then tax the operating facilities of the mines to the uttermost, and the small operations that proved of such utility in the time of need will again justify their reason for existence. Only those plants, however, that have kept equipment and apparatus in first-class working condition will be in position to reap the harvest.

EXAMINATION QUESTIONS

ANSWERED BY JAMES T. BEARD



British Columbia Examination First Class, Nov. 20, 1918

(Selected Questions)

Ques.—(a) Explain the difference between a force fan and an exhaust fan. (b) In case of a fire, if it becomes necessary to change an exhaust fan into a force fan, how would you do so? Give an intelligent sketch showing the arrangement necessary to effect the change required.

Ans.—(a) As far as the fan is concerned, the action is the same whether it is exhausting or forcing the air. Air is drawn into the central opening and thrown out toward the circumference of the fan where it is discharged. The difference between these two types of fans consists solely in their connection with the mine. When the fan is forcing or blowing air into the mine, the intake orifice is open to the atmosphere and the discharge is connected with the fan drift leading to the mine. On the other hand, if the fan is exhausting, the intake opening is connected with the fan drift and the air drawn from the mine is discharged into an expanding chimney that opens into the atmosphere.

(b) Referring to the accompanying figure, which is the plan of a fan arranged to exhaust air from a mine,

PLAN OF A REVERSIBLE CENTRIFUGAL FAN

in order to alter this fan to a blower, it is necessary to swing the four doors marked *A* to the positions indicated by the dotted lines. At the same time, it is necessary to cut off the discharge into the chimney and direct the air into the fan drift by swinging another door upward, which is not shown in the plan.

Ques.—Does a change in the barometer affect the volume of air passing through a mine? If 20,000 cu.ft. was passing, with a barometer of 30.5 in., what would be the result if the barometer dropped to 27 in.?

Ans.—A change in barometric pressure produces no appreciable effect in the volume of air passing through a mine ventilated by a centrifugal fan. A fall of barometer from 30.5 in. to 27 in. causes a corresponding decrease in the density of the air, which very slightly affects the efficiency of the ventilator but not to an extent to be appreciable. It has sometimes been assumed that an increase or decrease in the density of the air affects the friction of the air flowing through the mine, but the difference, if any, cannot be measured in the quantity of air passing.

Ques.—State what precautions you would use to prevent accidents and fires arising from defective installation of electricity in the mines, for power purposes.

Ans.—All installations of electricity for power purposes in mines should be in the charge of a competent electrician who is thoroughly familiar with mining conditions. As far as the mine officials are concerned, after the installation has been properly made and approved, every precaution must be taken to see that all rules and regulations are strictly obeyed. Any violations of the rules or tampering with electric wires or electrical installations should be suitably punished. Extra precautions must be used to prevent accidents from falling roof on entries and in passageways where power lines are installed. To avoid accidents from any defect in the installation, all power lines should be periodically and carefully inspected by an electrician, as he is the only one who can detect where an installation is defective.

Ques.—Describe what you consider a really efficient practical and economical system of watering dry and dusty mines.

Ans.—A watering system to be thoroughly effective, in a dry and dusty mine, should be installed by carrying a pipe line through the several airways and, particularly, on the haulage roads. The pipe should be arranged with perforations at suitable intervals, so as to furnish a good spray of water at these points, sufficient to keep the roads and entries in fair condition. It must be remembered, however, that no spraying system of this kind is wholly reliable as a preventive against the dangers of dust, and it is necessary, therefore, to clean all roadways regularly and thoroughly, so as to remove what dust is practicable from the roads and timbers. Branch pipe lines should be conducted to the face of each room or chamber, for the purpose of watering the working faces and the roads in the rooms. Sprinkling at the working face is more important even than the spraying of the haulage roads.

Ques.—Find the size of single pump required to pump 250 imperial gallons per minute from a depth of 500 ft. Effective steam pressure 60 lb. and piston speed 80 ft. per minute.

Ans.— Since the imperial gallon is 277.274 cu.in., 250 imperial gallons is $250 \times 277.274 = 69{,}318.5$ cu.in. Then, assuming the efficiency of the water-end of the pump as 80 per cent., the required plunger displacement is $69{,}318.5 \div 0.80 = 86.648$ cu.in. Then, the piston speed of the pump being 80 ft. per min., the sectional area of the plunger is $86{,}648 \div (12 \times 80) = 90.26$ sq.in. The diameter of the plunger is, therefore, $\sqrt{90.26 \div 0.7854} =$ say $10\frac{3}{4}$ in. But, making due allowance for slippage, we assume a 12-in. plunger. For a head of 500 ft. and allowing 20 ft. additional for friction head, the pressure on the water-end is $520 \times 0.434 = 225$ lb. per sq.in. An available steam pressure of 60 lb. per sq.in. will require a steam cylinder of $225 \div 60 =$ say 4 times the area or twice the diameter of the plunger.

FOREIGN MARKETS AND EXPORT NEWS

EDITED BY ALEX MOSS

Coal-Mining Situation in France and Belgium

The problem of supplying coal and coke for France and Italy is the most serious economic question of the day, states George S. Rice, in a report made to Van H. Manning, director of the U. S. Bureau of Mines. Mr. Rice is abroad as a member of a commission sent to observe reconstruction conditions and methods in foreign countries.

Before the war France consumed annually about 62,000,000 metric tons of coal. Production, on the other hand, amounted only to 41,000,000 metric tons, which meant that France imported annually about 21,000,000 metric tons of fuel in order to round out her requirements.

The principal coal basin of France is the Nord-Pas de Calais. Three-fourths of this area was occupied by the Germans in 1914 and nearly the whole of the rest of the basin was brought under artillery fire. The coal production was reduced to about 8,000,000 tons, normal production being nearly 30,000,000 tons. It will take from two to five years to increase this amount materially, and perhaps ten years to get back to the normal prewar production.

Belgium before the war consumed 27,000,000 metric tons of coal per year, while the output from her mines amounted to 23,000,000 metric tons annually. Belgium both imported and exported fuel in the prewar period, her imports totalling 9,000,000 metric tons and her exports 5,000,000 metric tons.

The coal mines of Belgium were not destroyed by the Germans, as the latter intended to retain possession of the country. The production has dropped from 23,000,000 metric tons in 1913 to 14,000,000 in 1918, which is a reduction of 40 per cent. The number of workers has been reduced from 145,000 in 1913 to 110,000 in 1918, or a reduction of 24 per cent. The coal mines of Belgium are expensive to operate, and the industry has been greatly disorganized by German occupation. The Belgium coal production will be slow in reviving.

Annual deficits are to be faced in France and Belgium for several years, as can be seen from the following tabulation:

	Metric Tons
Destruction of French output	20,000,000
Reduction of Belgium output	9,000,000
Normal French import over export	21,000,000
Normal Belgium import over export	4,000,000
	54,000,000
Normal output Saar Valley	16,500,000
Now reduced by labor troubles to	12,000,000
Total shortage (considering supply from Saar Valley)	42,000,000

The destruction of metallurgical plants in Belgium and France will lessen the immediate need for fuel by about 12,000,000 metric tons. Pending the rebuilding of plants and the rebuilding of the industry during the next five years or more, there will be a total deficit of about 30,000,000 metric tons of coal per year in France and Belgium.

Great Britain exported before the war 15,000,000 metric tons of coal to France and Belgium, and 9,000,000 metric tons to Germany, making a total of 24,000,000 metric tons exported. Coal production in England has been reduced on account of a shortage of labor.

The Saar Basin politically has three divisions with normal outputs as follows:

	Metric Tons
Prussia	12,000,000
Bavaria	1,500,000
Lorraine Annex	3,000,000

Lorraine Annex will be returned to France. There are some possibilities of further extensions in this part of the Basin. The Bavarian portion is a small corner without much possibility of further development. The Prussian area is the property of the state, thus making it easier to shift ownership or control to France. At the present time all the mines of the Saar Valley are supervised by the French military authorities. Wages have doubled and trebled since the war began.

In the foregoing consideration, Luxemburg has not been counted nor have the needs of Lorraine Annex. Westphalia should be called on to supply these districts and also Holland, which country normally imports 2,000,000 metric tons from Great Britain and over 7,000,000 metric tons from Germany.

English Coal Markets

The outstanding feature of the week's principal coal markets, says the *Iron and Coal Trades Review* of May 9, has been a continual scarcity of fuel supplies. Prices remain fixed for home consumers, but the cost of export coal advances.

In the Tyneside markets the coal situation shows little alteration, though a number of collieries report things as more satisfactory. The inquiry for fuel is heavy from most quarters, and the area of demand is extending.

Throughout Yorkshire and the Midlands, with production better maintained, supplies generally are easier. There is a strong belief that the ban on exports from these districts will be lifted shortly. There is practically little fuel offering in the open market, and prices remain unaffected.

In the South Wales area pressure for all classes of coal continues; and with supplies so limited and Allies receiving preference, it is next to impossible to secure any quantities for export to neutrals.

Conditions in the Scottish coal markets are moving along from day to day without much variation. Outputs are being disposed of without much difficulty, as the demands for home purposes are still fairly good. Surplus tonnages not required for local consumers is readily taken up for export.

Slow in Getting Coal Export Program Under Way

Considerable dissatisfaction is in evidence as to the progress made in getting the export coal trade under way. The methods thus far devised are not regarded as promising. There is complaint arising from the rates which the Shipping Board will charge. It is feared that American exporters will be unable to compete with the English rates, which are said to be much lower.

There is no question, however, that considerable business is to be done with northern Europe and Mediterranean ports. There is little hope, however, of establishing permanent markets. By taking advantage of the present situation and rushing coal to those markets in the largest possible quantities, it is believed that very respectable profits can be made in the near future. This business is being handled with the same idea as had distant dealers in building materials when they rushed large stocks into Baltimore and into San Francisco after the disasters in those two cities. They made large profits for the time being, but had no hope of holding the business permanently. In addition to the financial profit, there will be the important benefit of the experience.

So far as a permanent export market for coal is concerned, the really fertile field is limited to Latin America and to Canada. All are agreed that it is an economic necessity for the country to do an export coal business, but confronted by the Shipping Board's high rates and a decided timidity on the part of the Government to assist, the way that it is going to be accomplished is not clear. Some are of the opinion that coal men at least "cannot hunt business in gangs." When attention is called to the fact that Germany was very successful "in hunting business in gangs," the answer given is that Germany had a government which was not afraid to offend other governments. Nevertheless, there is intense effort being put forth in Washington to reduce the formidableness of the obstacles which confront coal exportation, and it is practically certain that a workable plan will be hit upon finally.

Possibilities for Swedish Coal Imports from America

Sweden is almost entirely dependent on England for its coal supply. Lately coal has been coming into Sweden in quantities approximately but one-third of normal which, of course, is seriously affecting Swedish industry, primarily the iron and steel industry, reports Trade Commissioner Norman L. Anderson, Stockholm. This serious coal shortage has brought forth a great deal of comment relative to the possibilities of obtaining coal from America. Mr. Anderson has been approached by a number of Swedish business men who desire to import coal from the United States, the chief obstacle being, of course, the tonnage situation. Below is given a translation of an article bearing on the subject, which appeared in *Svensk Handelstidning* for Mar. 16, 1919:

Otto Wallenius, a wholesale dealer in Goteborg, has made some rather pessimistic statements concerning the possibilities of importing American coals to Sweden. He points out that an offer, made a month ago, for importation of considerable quantities of coal has been dropped, partly because the price offered, 103.50 crowns ($27.7 per ton is considered too low with the present high freights, especially inasmuch as return cargoes are lacking.

Mr. Fürst, chief of the Swedish Handelskommission (Trade Commission), on the contrary, has pointed out to *Svensk Handelstidning* that the import of American coals does not seem to be impossible. The Handelskommission as well as some private importers are for the present negotiating about it.

According to information the import as regards the Handelskommission would comprise 50,000 tons. As matters stand at present it is, however, very difficult to express any opinion as to the quantity that may be obtained. The whole question depends on the freighting possibilities. The prospects of getting Swedish tonnage are very small, partly because there has lately been a great lack of tonnage, not least because the vessels have been detained for months in English coal ports, and partly because of lack of return cargoes to America. The Handelskommission counts exclusively on American tonnage, of which there seems to be an ample supply. It is not considered impossible, either, to arrange home freight for American vessels from England or perhaps other countries.

Before the war only a small quantity of American coal was imported to Sweden. Therefore it may now be difficult to sell American coal to Swedish coal consumers. Before deciding on any larger coal importation from America, Mr. Fürst further pointed out that it is necessary to ascertain whether there will be a large Swedish market for American coal. If this proves so, which Mr. Fürst for his part does not doubt, one need not give up all hope of importation, especially as there is every reason to expect that the tonnage problem will not be so difficult to solve after the war, as was first feared. Besides, coal import from America has already begun. As is known, the Swedish state railroads have bought 30,000 tons, the first cargoes of which are expected to arrive in Swedish port by the end of this month.

In a conversation that *Svensk Handelstidning* has had with coal import firms in Stockholm, it is pointed out that American coal suppliers have offered coal to several Swedish importers at a price varying between 105, 115 and 117 crowns per ton, and even more, c. i. f. Goteborg. The Stockholm importers, however, do not wish any reloading in Goteborg, as that would make the coal still dearer. Besides, they can hardly bear any reloading and therefore the importers wish the coal delivered directly to Stockholm.

COAL AND COKE NEWS

What Happened in May

[The bracketed figures in the text refer to the number and the page of the volume in which references to the matter noted may be found and should the reader desire further information he can obtain it in the place indicated.]

May 2—The United States Circuit Court of Appeals hands down a conditional affirmation of the judgment rendered by the District Court in the case of the Coronado County Mining Co., of Sebastian County, Ark. vs. the United Mine Workers of America [XV, 873]—The large breaker of the Delaware & Hudson Co., at Jermyn, is closed for an indefinite period. Coal from the Jermyn mines will be sent to the Powderly breaker [XV, 929]—Charles D. Neill hands down a decision under which 200 contract miners of the Lehigh & Wilkes-Barre Coal Co. will receive back pay for work done since 1917. The point at issue was payment for the removal of rock in the robbing of pillars. [XV, 916].

May 3—A disastrous accident occurs at the mine of Old Ben Coal Corporation, at Buckner, Ill. As several men are being hoisted out of the mine on a cage, one is killed and three others are injured. [XV, 930]—As the result of a mine fire on No. 12 east gangway, Nottingham Mine, of the Lehigh & Wilkes-Barre Coal Co., 50 men nearly lose their lives. They are brought to the surface in a serious condition, being overcome by blackdamp [XV, 885]—The Victory Loan drive ends at 12 o'clock, midnight—The coal-export committee of the American Mining Congress meets at a luncheon in the rooms of the Machinery Club, 50 Church St., New York City. The meeting votes to appoint a committee to prepare a report and recommendation for coöperative effort to be submitted to a general conference [XV, 867]—The Western Coal Operators' Association of Canada meets and discusses the position of the coal industry in regard to the labor question [XV, 1093].

May 5—Charles P. Neill rules that contract miners who are taken off their regular work for an emergency job shall be paid the rate called for in their scale if the pay for the other job is less [XV, 916]—A cage containing ten miners drops 1100 ft. at the Maple Hill shaft of the Philadelphia & Reading Coal and Iron Co., resulting in the death of one miner and the serious injury of the nine other men, two of whom may die [XV, 885].

May 7—A new workmen's compensation bill is introduced at the Pennsylvania legislature by Senator Smith [XV, 929]—The peace treaty and the constitution of the league of nations (one document) framed by the peace conference at Paris, is handed to the German plenipotentiaries—The Mt. Jessup Coal Co.'s employees, to the number of 400, go on strike, leaving only the company men at work. The men claim that their wages are being reduced [XV, 916]—The Racket Brook Coal Co.'s 300 employees declare a strike because the company refuses to reinstate a motorman and brakeman who had been discharged [XV, 916].

May 8—An open market for steel products is created when representatives of the Railroad Administration and members of the general committee of the American Iron and Steel Institute fail to agree on minimum stabilization prices—Charles P. Neill rules that mine workers cannot be expected to be reinstated in their jobs if the operators can show that they were discharged for incompetency, in dismissing the complaint of H. C. Singley against the Evans Colliery Co., of Beaver Meadow, Penn.

May 9—The resignation of the Industrial Board, George N. Peek, chairman, is accepted by Secretary Redfield. Upon retiring the board releases all industries from its findings—State mine inspector Frank Rossbottom, of Illinois, announces that the conference between miners' representatives, operators and school authorities to be held in Duquoin, Ill., today, is postponed until June 6. Vocational training is to be discussed [XV, 929].

May 10—Attorney General A. Mitchell Palmer makes public an opinion to the effect that the Redfield plan for stabilizing prices in industry violates the anti-trust laws; he declares price fixing illegal. Any modification of statutes upholding a non-competitive policy must come from Congress.

May 15—All rules, regulations or orders issued by the U. S. Fuel Administrator, H. A. Garfield, relative to oil and gas, are set aside. The annual meeting of the Central Pennsylvania Coal Producers' Association is held at Altoona, Penn. Addresses are made and officers elected [XV, 1017].

May 16—The Northeast Kentucky Coal Association holds a special meeting at Ashland, Ky. Income tax statements and freight rates are discussed [XXV, 1018]—The Central Pennsylvania Coal Producers' Association holds its annual meeting at Altoona. Officers are elected [XV, 1017]—A special meeting of the operators of northeast Kentucky is held at Ashland, Ky. [XV, 1018].

May 20—Compensation amendments proposed by the Pennsylvania state administration bill are given a hearing before the Senate judiciary general committee at Harrisburg, Penn. [XV, 1016]—Amendments to the Mangan bill are proposed in the Pennsylvania Senate judiciary general committee [XV, 1916]—Congress opens at Washington, D. C., and President Wilson's message is read to the two houses.

May 22-24—The National Coal Association holds its annual meeting at Chicago in the Congress Hotel. The convention elects officers for the ensuing year [XV, 1000].

May 26—The Caldwell Bill, proposing a loan of the Government's surplus machine tools to various technical institutions in the U. S., is introduced in the U. S. House of Representatives [XV, 1090].

May 27—Men at one of the mines of the New River Co., in Raleigh Co., W. Va., return to work. Miners at another nearby mine of this company remain on strike—a question of electrification of an incline [XV, 1052].

May 27—The Ohio Valley Coal Operators' Association secures an order from the Interstate Commerce Commission directing the railroads to make marked reductions in rates on coal from western Kentucky [XV, 1063]—John P. Reese, vice president and general manager of the Chicago & Northwestern coal properties, dies at his home in St. Louis, Mo. [XV, 1065].

May 28—The administration compensation bill is reported to the Pennsylvania state Senate judiciary special committee [XV, 1063]—A committee of senators of the Pennsylvania Legislature confer with anthracite coal operators in regard to the mine cave question [XV, 1063].

May 29—It is recorded that all mine workers are out in District No. 18 (eastern British Columbia and Alberta) as a result of a disagreement about wages [XV, 1052]—The Shipping Board holds a meeting of representatives of producers, exporters and brokers at which the export situation is discussed [XV, 1060].

May 29-30—The first meeting of the Coal Mining Electricians' and Mechanics' Institute is held at Charleston, W. Va. [XV, 1076].

Harrisburg, Penn.

Efforts of representatives of employers to amend the workmen's compensation bill, in the face of the opposition of Governor Sproul and Attorney General Schaeffer, failed in the Senate on June 11. As a result the bill, which increases the scale of compensation, remains on the calender.

B. M. Clark, representing the bituminous coal interests, states that the basis on which compensation was computed in the bill as it stands amounts to more than the 60 per cent. which the bill is supposed to allow and is "Unreasonable, unjust and unfair." In some cases the compensation to be paid to beneficiaries of the bill would amount to as high as 125 and 150 per cent.

Charles F. Huber, president of the Lehigh & Wilkes-Barre Coal Co. also objected to a provision of the bill which does not deduct amounts for materials, supplies, tools and other things furnished to miners in computing wages received. He suggests that "materials, supplies and tools and other things" be included in the deduction.

The bill provides that in computing a man's wages with regard to continuous employment the wages shall be taken to be five and one-half times his average earnings at the rate for a working day fixed before an accident occurs and using, as a basis of calculation, his earnings during so much of the preceding six months as he worked for the same employer.

The amendment which it was sought by Mr. Clark to insert in the Senate bill provided that a man's average weekly earnings are to be ascertained by dividing his total earnings for so much of the preceding twelve months as he was in the employ of the employer, by the number of calendar weeks in such period; deducting, however, from such divisor and full weeks or fractional parts thereof during which he was prevented from working by reason of his own sickness, as evidenced by affidavit of attending physician.

Workmen in the mining regions of the state will be interested in an opinion given by Deputy Attorney General Hargest to state Chief of Mines Seward E. Button, to the effect that a man coming to this country with his parents, while still under twenty-one years of age, becomes a citizen without naturalization and that he is eligible for a certificate as fireboss in a mine.

Uniontown, Penn.

Official announcement has been made of the sale of all of the former holdings of J. V. Thompson, at the time of his failure the largest single holder of coal lands in the world, to the Piedmont Coal Co., a Pennsylvania corporation, for a sum approximating $18,000,000. Of this sum $5,500,000 is to be paid in cash and is for the unsecured creditors of Mr. Thompson, returning approximately 43c. on the dollar of unsecured claims. The secured indebtedness assumed by the purchasers totals between $12,000,000 and $13,000,000.

The actual identity of the Piedmont Coal Co. is withheld, but in financial circles which have been watching the negotiations there is a general impression that the company is a subsidiary or is affiliated with the United States Steel Corporation, and that the Hope Natural Gas Co. may be interested in the deal which involves the West Virginia holdings. Samuel McClay, an attorney, of Pittsburgh, is president of the Piedmont Coal Co., and William T. Irwin, of Pittsburgh, treasurer of the Union Trust Co. of that city, is also treasurer of the Piedmont Coal Company.

During the past two years the trustees have sold, under approval of the court, coal lands totaling in sales $6,500,000, bringing the total returns from the properties to around $25,000,000. The appraisement made by the receivers in 1915 estimated the value of the properties at $65,000,000. This appraisement included all of the properties turned over to the receivers, and showed the principal holdings of Mr. Thompson in 1915 to be as follows: Greene

County Holdings—Acreage 58,403.79, valued at $32,047,900.50. Washington County Holdings—Acreage 10,172.29, valued at $3,150,186.60. West Virginia Holdings—Acreage 72,103.03, valued at $18,868,841.55. Fayette County Holdings—Acreage in coal, 735, acreage in surface, 7,877.40, all valued at $2,646,500. Plant and factory sites in Allegheny, Armstrong and Beaver counties, Pennsylvania, valued at $1,557,500.

Charleston, W. Va.

Coal production in central-southern West Virginia was retarded during the first ten days of June by a car shortage confined to no one railroad system although at the end of the period mentioned the car situation had shown some improvement but was still hampering production to an appreciable extent. The continued reduction in no-market losses was more than offset by the increase in car shortage losses. The car shortage was attributed to congestion at Lake ports where the pooling of coal has been discontinued.

During the first ten days of June export shipments were increasing in volume insofar as was possible under transportation conditions existing during the period referred to, the demand being in fact insistent for coal from this particular producing section. Production from the Kanawha River south was reduced at least one-third, generally speaking, by the scarcity of cars, inadequate man power also being a factor in holding down production. The demand for coal on the Lakes was strong. Gas coal also showed considerable activity.

There would have been a much heavier tonnage out of the Kanawha district during the first ten days of the month but for lack of cars in a part of the district.

Strange to say while some parts of the field felt the need of cars others had a plentiful supply. Cabin Creek operations found it almost impossible to secure cars. The mines of the district were unable to produce more than 60 per cent. of the normal output, the general demand being such as would have justified a much larger production. Consequently some mines were limited to only about half a week's operation, although increased demand for all grades would have, under ordinary circumstances, stimulated production. The demand for Kanawha gas coal was becoming more insistant.

Up until June 10 the Chesapeake & Ohio was unable to furnish cars in sufficient quantity to meet the requirements of the mines. As is generally known, New River smokeless is in strong demand just now, not only in domestic areas but in the export trade. Much coal has been going to the Lakes as well as to New England and the supply for these markets was cut off to some extent by the shortage of cars. A scarcity of miners was also a factor in restricting the output.

The report was in circulation on June 10 in the New River field that an embargo had been placed for the time being on shipments to the Lakes owing to congested conditions. The demand for prepared sizes of smokeless is such that this particular grade is now quoted at $4. a ton, run-of-mine ranging from $2.75 to $3 and over. There is in evidence a much better demand for slack.

A 20 per cent. loss in production amounting to 71,000 tons was sustained in the Logan mining district, through car shortage alone. This was almost half of the entire production loss of 47 per cent. and the total production loss was 164,000 tons. The bulk of the remaining loss arose from no market—75,000 tons. Other sources of loss were almost negligible, but the increase in the car shortage loss which was almost double, was more than sufficient to offset the no market gain. As there were 182,000 tons produced it will be seen that but for lack of equipment mines of the district might have exceeded production for the same period of 1918 which was only 194,000 tons. The report covering May production shows 795,000 tons mined as against 1,023,000 for May of last year. May production averaged 54 per cent. of capacity which was 1,472,000, there being therefore during May a production loss of 676,000 tons. Logan coal is in much stronger demand both on the Lakes and in eastern markets. This is particularly true of gas coal.

Fairmont, W. Va.

Conditions in northern West Virginia coal producing fields during the first seven days of June were altogether different from those prevailing elsewhere in the state, at least insofar as transportation facilities were concerned. The cars furnished were ample for all requirements even though the outgoing tonnage was slightly augmented because of additional orders. Figures already compiled show that May was the best month of the year from the standpoint of production, the total shipments from the mines around Fairmont amounting to 876,000 tons. In April shipments totaled 695,000 tons.

Railroad fuel shipments were heavy throughout May, the railroads taking more than a third of the coal mined, 2123 cars went to the Lakes. It was evident during the first third of June that slight gains were being made in Lake shipments as well as to tidewater and more mines were engaged in getting out coal for export. Railroad fuel was averaging much more than a third of the total shipments. A further expansion of export shipments is looked for after July 1 when more boats will be available.

That inroads are being made on the producers of the Fairmont and other northern West Virginia regions by Ohio and Illinois operators insofar as the Lake trade is concerned is the feeling of some coal men in this section. Illinois producers as well as those in eastern Ohio have succeeded in getting a large slice of Lake business during the present year.

Birmingham, Ala.

Extensive developments in the Birmingham mining district, inaugurated by the Woodward Iron Co. two years ago, are about completed; the greater part of the new plants are ready for operation and are expected to start up during this month. The new coal mine on the company's railroad between Dolomite and Mulga is nearly completed. This is one of the large slopes of the country. The mine is equipped with every modern device, and the slope is double-tracked its entire length. Approximately 2000 men will be given employment in and around the new mines.

In addition to proving adjacent properties by drilling, three new tipples have been completed at the Dolomite openings. Each of these tipples have two dumps. With the blowing in of the third furnace at Woodward recently, it is understood that the night shifts at the mines will be resumed.

Coal fields heretofore undeveloped and without means of transportation at present will be opened up, if approximately 60 miles of navigable water are added to the Warrior River; construction of an additional dam and lock on that river may be recommended to Congress by a surveying party of United States engineers who are said to be investigating the situation. Development of the proposed project would afford an outlet for coal lands in Walker and Jefferson counties.

This investigation is authorized under an act of Congress of July 27, 1916, directing a preliminary examination and survey of Mulberry Fork of the Warrior, above Sanders Shoals. Completion of the proposed improvement, it is stated by Col. R. S. Thomas, engineer in charge, would provide 60 additional miles of navigable water to mine operators using the Black Warrior, affording outlet to coal lands noted.

Nanaimo, B. C.

A largely attended meeting was held recently at Nanaimo, B. C., to protest against the action of the lieutenant-governor in withholding his assent to the legislation passed by the Provincial Legislature in 1918 giving settlers within the Esquimalt & Nanaimo Railway belt an opportunity to claim the coal rights on their property. Addresses were delivered by Hon. Wm. Sloan, Minister of Mines; J. H. Hawthornthwaite, Member of Provincial Parliament, and Harvey Murphy, the latter being president of the Nanaimo Board of Trade. The former went fully into the history of the settlers' struggle for the coal on their property and argued that they were asking no more than justice, which should be accorded. Messrs. Hawthornthwaite and Murphy encouraged the claimants to persevere, assuring them that, with right on their side, they would be successful. The following resolution was enthusiastically carried:

"That this meeting emphatically protests against the action of the lieutenant-governor in refusing his assent to the settlers' rights bill and demands that consideration of assent be given forthwith. And be it further resolved, that this meeting protest against any invasion of recognized provincial rights."

PENNSYLVANIA

Anthracite

Scranton—For a number of years I. W. W. agitators have harassed the Jermyn Coal Co. in the operation of its colliery near Scranton, and this, together with the high cost of operation, has caused the company to close down.

Harrisburg—The Pennsylvania Department of Mines announces that no examination of mine inspectors will be held this year. Furthermore, it is stated that the report of this department is still in the hands of the state printer.

Hazleton — Local companies report an increase in New England orders, which were cut off by official rulings during the war.

Wood-pulp pipe in standard sizes has been introduced in this field and will be given a test where acid mine water causes pipe-line trouble.

Dunbar — Damage aggregating $20,000 was caused by fire at the Freeport No. 2 mine of the American Manganese Co. at Dunbar when the tipple, 15 cars loaded with coal, fan house, blacksmith shop, office, repair shop and motor shed were destroyed. It is expected that it will require two months to complete repairs. The origin of the fire has not been ascertained.

Bituminous

Confluence—The Laurel Coal Mining Co., of this place, whose mines are located on the Western Maryland R.R., started about nine months ago to modernize its plant. The improvements are completed and include: An electric plant and Sullivan coal-mining machines and an Ironton storage-battery locomotive. The company expects to materially increase its production. J. H. C. Barr is general manager and W. R. Jones is mine superintendent.

Clearfield—M. D. Kelly, of the Kelly Bros. Coal Co., at Snow Shoe, which has mines at Snow Shoe, Karthaus, Houtzdale, Cherry Run and Kate Glen, a few days ago sold 5500 acres of coal land situated in the lower end of Clearfield County to Pittsburgh capitalists for $225,000. The company intends to make improvements costing $150,000. It is expected the new operations will have an output of two or three thousand tons a day by the first of the year.

Uniontown—Within the past few days it is stated that contracts aggregating 210,000 tons of coal have been placed for railroad fuel, resulting in increased operations at a number of Fayette County mines. There is also a well authenticated rumor in coke circles that four cargoes of export coke have been shipped from this section within the past four weeks.

The Republic Iron and Steel Co. made largely increased coal shipments from its Republic and Martin mines during the first part of this month, though the company is not firing any additional ovens. The Century Coke Co., near Brownsville, fired 50 ovens recently, making the half of their ovens now in blast. The H. C. Frick Coke Co. is also making additional coal shipments. The W. J. Rainey Co. is firing additional ovens at its Allison and Royal plants.

WEST VIRGINIA

Bluefield—Colonel William Leckie, of Welch, recently purchased an office building here with the intention of making it the headquarters and offices of the ten coal companies in which he is interested. It is stated that an annual business of $1,500,000 will be brought to Bluefield by this deal. Colonel Leckie expects to move from Welch and make his home in this place.

Fayetteville—Five hundred and forty acres of coal land in Fayette County have been leased by the Bee Lick Knob Coal Co. from the Sewellmont Coal Co. on a royalty basis, the lease to run for a period of 40 years. Under the terms of the lease, the lessor is to receive a royalty on not less than 20,000 tons for the first year, 40,000 for the second year, and 80,000 for each year thereafter. Royalty is to be at the rate of 15 cents a ton on coal and 22 cents a ton (short) on coke.

Fairmont—C. H. Tarleton, manager of the West Virginia division of the Consolidation Coal Co., announced the following changes in mine superintendents which were effective June 1: Robert Heann, in charge of mine No. 55 is transferred to mine No. 24, as superintendent. Vice W. J. Davis, who is transferred to mine No. 43 as foreman, J. H. Nuzzum is to act as superintendent of mine No. 55 until other arrangements are made.

Charleston—A lease on 302 acres of coal land on Lens Creek in Kanawha County has been made to John Steptoe by the Lens Creek Coal Co. for a period of 25 years, the lease including buildings and mining equipment and the consideration being $5000 in cash and $13,000 in promissory notes, a royalty of 30c. a ton to be paid during the life of the notes and 10c. a ton after they are paid. The lessee is required to pay royalty on a minimum production of 24,000 tons.

Page—Beard's Fork is now the center of mining activities for the Loup Creek Collieries. Here the company has two mines developing about 2000 acres of No. 2 Kanawha coal. One tipple is used for both mines, a retarding conveyor having a capacity of 300 tons per hour being used between mines and tipple. Inside equipment consists of Jeffrey and Westinghouse locomotives and Jeffrey short-wall mining machines. There are eight pairs of openings at the north and six pairs at the south mine. The company has also finished construction work on 125 miners' cottages equipped with electricity.

OHIO

Glouster—Chief Deputy Jerome Watson, of the state Department of Mines, and Deputy Inspector Andrew Ginnan are making an inspection of coal mines in this section and in the Hocking Valley. They are especially interested in mines which connect with the workings of adjoining plants. When the inspection is completed these officials will have information to assist them in making recommendations to further safeguard employees in these mines.

ILLINOIS

De Soto—The Peacock Coal Mining Co. is now sinking its main shaft down to the No. 5 seam, which is about 50 ft. below the No. 6 seam. The coal taken from the drill holes shows up so exceptionally well that it is planned to work both of these beds at the same time, which is something that no other mine in southern Illinois is doing.

Duquoin—The J. R. Crowe Coal and Mining Co., of Kansas City, has leased approximately 3500 acres of coal lands located two miles southwest of here. The Crowe company is one of the largest operators in the southwestern district of Kansas, and is also identified with coal interests in Missouri. Engineers are on the ground making a survey to determine the best location for a new mine. The plant will be modernly equipped and will be connected with the Illinois Central R.R. This is the first venture in the Illinois fields for the Crowe company.

Niantic—Early on the morning of June 10 fire destroyed nearly all of the upper works of the Niantic Carbon Coal Co.'s plant, near here, causing a loss of $40,000 or more. The origin of the fire is unknown; it was discovered by the mine engineer. Five mules down in the mine were suffocated, but fortunately no men were in the workings at the time. The fire started in the screen house and spread to the other buildings; two carloads of coal also were consumed. Considerable smoke entered the mine but the flames did not penetrate the workings. The mine has been in operation about 30 years and employs 100 miners. The owners of the mine are J. M. Dorcine, David Beggs, Daniel Macknet, Frank Shields, Chester Russell, and B. T. Wagoner. The property was partly insured and will be rebuilt without delay.

Benton—The Chicago, Wilmington & Franklin Coal Co. has purchased from Mr. and Mrs. Robert Williams, of Flint, Mich., the mine here which has been operated by the Benton Coal Co. The consideration is understood to have been about $1,500,000. This gives the company three mines in this section; it recently acquired the Hart-Williams mine and has operated the big colliery at Orient for about six years. The purchase of the two former mines, with mineral rights, links up the properties of the companies from Benton to Orient, some seven miles. The Benton Coal Co.'s mine was sunk about 17 years ago. In the past year improvements costing about $250,000 have been made at this plant, including the installation of a new rescreening plant. In 1918 The Benton company produced 437,364 tons of coal.

Personals

William Littlejohn has been appointed general superintendent of the Utah company, with headquarters at Castle Gate, Utah, in the place of J. S. Thompson, deceased.

E. A. Hitchcock has recently become connected with the Bailey Meter Co., of Cleveland, Ohio, as vice president. He will supervise the training of technical graduates for the company's service and sales departments.

Charles F. O'Hagan, formerly chief engineer of William B. Scaife & Sons, of Pittsburgh, Penn., will be resident engineer and manager of this company's Chicago office when it opens on July 1, as a sales and engineering department.

Mark R. Lamb is at Duquoin, Ill., where he is examining the underground coal loading equipment of the Union Colliery Co., in connection with similar equipment for coal mines in France. At this mine coal is hoisted in skips which permits of large tonnage with moderate rope speed.

M. H. Jones, who has been connected with the Westinghouse Electric and Mfg. Co. for the past 15 years, as assistant to manager of the Philadelphia district, has resigned his position with that company to become sales manager of the Standard Electric and Elevator Co., of Baltimore, Md.

Major Donald Markle, of Hazleton, who served with the Fourth Division in France, resigned, on June 8, from the Cranberry Creek Coal Co. and the Harwood Coal Co., to become general manager of the Blair-Cambria Coal Co. (a bituminous operation), and of the Altoona Northern Railroad, a fourteen-mile line connecting the coal mines with Altoona.

F. R. Lyon has been made a vice president of the Consolidation Coal Co., having been general manager of this concern since 1913. He entered the services of the company as manager of the Maryland division. **A. Brooks Fleming**, who started as a mine superintendent of the company, has been selected as assistant to the president. Mr. Fleming was production manager in northern West Virgina during the war.

Coming Meetings

The Missouri State Retail Coal Merchants' Association will hold its second annual meeting in St. Louis, Mo., on Monday and Tuesday, June 23 and 24, at the Planters' Hotel. Secretary, E. J. Wallace, St. Louis, Mo.

American Institute of Mining and Metallurgical Engineers will hold its fall meeting Sept. 22 to 26 in Chicago, Ill. Chairman Chicago meeting, Carl Scholz, 547 West Jackson Boulevard, Chicago, Ill.

American Institute of Electrical Engineers will hold its annual convention at the Lake Placid Club, Adirondacks, N. Y., June 24 to 27. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

Northeast Kentucky Welfare and First Aid Association will hold a first-aid contest July 4 at Pikeville, Ky. Secretary, E. H. Sowards, Pikeville, Ky.

The Rocky Mountain Coal Mining Institute will meet in Salt Lake City the first week in July, 1919. Secretary, F. W. Whiteside, Denver, Colo.

Mine Inspectors' Institute of the United States of America will hold its annual meeting July 8 to 11 at Indianapolis, Ind. Secretary, J. W. Paul, Pittsburgh, Penn.

The National Commissary Managers' Association will hold its annual meeting August 5-7 at the Sinton Hotel, Cincinnati, Ohio. Secretary, D. J. Eichoff, Manhattan Building, Chicago, Ill.

Pennsylvania Retail Coal Merchants' Association will hold its annual meeting July 23 and 24 at Reading, Penn. Secretary, W. M. Bertolet, Reading, Penn.

National Exposition of Chemical Industries will hold its fifth annual meeting at the Coliseum and First Regiment Armory, Chicago, Ill., during the week of Sept. 22. Manager, Charles F. Roth, 417 South Dearborn St., Chicago, Ill.

Industrial News

Moundsville, W. Va.—The Dunkard Valley Coal Co. has purchased 7½ acres of land and coal from Davis Powers—consideration $3750.

Baltimore, Md.—The Standard Electric and Elevator, Inc., has opened a New York office at 280 Broadway, in charge of C. A. Yarrington, formerly sales manager of the company.

Cleveland, Ohio—The Lincoln Bonding Co. has opened up a Chicago office at 504 Fisher Bldg. This new branch of the company is under the supervision of W. C. Burdick, sales manager.

Uniontown, Penn.—Negotiations have been completed by the Callahan Coal and Coke Co. for the purchase of a total of 435 acres of coal located in Lower Turkeyfoot Township, Somerset County, formerly held by Harry N. Mitchell.

Senecaville, Ohio—The Akron Coal Co. has awarded the contract to the J. W. Williamson Co., Columbus, for construction of a tipple at the Rigby mine which it will open here. A shaft 175 ft. deep will be necessary.

Thacker, W. Va.—The Thacker Coal and Coke Co.'s plants at this place have resumed operation, after being closed down since Feb. 1. These mines are large producers, employing over 600 men. The company is controlled by the Houston interest.

Ebensburg, Penn.—The Commercial Coal Mining Co. is understood to be arranging for the development of one of its lower seams of coal by a slope opening on its holdings in the vicinity of Red Mills, Blacklick Township, to provide for increased operations.

Pittsburgh, Penn.—The Pittsburgh Coal Co. has recently completed negotiations for the purchase of a tract of coal located at Amwell Township, comprising about 15½ acres, and a site in Canton Township approximating 108 acres. It is said that the company is planning for development.

Sergent, Ky.—It is announced that Jouett, Biglow & Brooks, of Cincinnati, have taken over the Cumberland-Hazard Coal Mining Co.'s property near here. The name of the corporation is to be changed to the Florence Mining Co. and a number of improvements in the plant are contemplated.

New York, N. Y.—The Macomber & Whyte Rope Co., of Kenosha, Wis., announces the opening of a branch office at this place at 30 Church St., under the management of E. E. Robirds. Mr. Robirds has been with this company for 10 years, having been successively manager of the Pittsburgh and Chicago offices.

Portsmouth, O.—The Welston-Hill Coal Co. has recently completed negotiations for the acquirement of the holdings of the Coalton Fuel Co., Washington Township, comprising a total of about 440 acres. It is understood that the new owner will continue operations on an increased scale. Homer Goddard is president and Earl Littler, secretary.

Coal Run, Ky.—C. E. Steele, owner of the Coal Run Coal Co. at this place, and manager also of the Funk Coal Co., at Sutton, Ky., has sold his interest in the Coal Run company to H. H. Funk. Pending the resumption of operations at the Funk company's plant, many repairs have been undertaken and much construction work is in progress so as to fit the mines for increased output when operations are resumed.

New York, N. Y.—The New York Testing Laboratories which have been organized by L. R. Seidell, G. B. Jack, Jr., and H. H. Geist, formerly chief metallurgist, assistant chief metallurgist and chief chemist, respectively, of the Wright-Martin Aircraft Corporation, have in addition to their well equipped laboratories at 354 Mulberry St., Newark, N. J., opened up their New York Offices at 74-80 Washington St. In addition to chemical and physical testing and microphotography, this organization is specializing in the source inspection of materials, and as consultants in smelting, foundry, drop forging and heat treating practices and metallurgical investigation of shop troubles. They are also making chemical investigation of various ore and mineral deposits, their application to industrial purposes and possibilities of marketing same.

MARKET DEPARTMENT

EDITED BY ALEX MOSS

Weekly Review

Buying Improves and Domestic Grades of Soft Coal Strengthen in Price—Labor Problem Promises to Be Difficult of Solution—Mines Working 50 Per Cent. of Capacity —Anthracite Domestic Sizes in Urgent Request

REPORTS coming from the important soft-coal consuming sections indicate that buying is somewhat more pronounced and that there is a tendency toward a strengthening in prices of the high-grade domestic bituminous coals. The matter of disposing of the steam sizes still remains a problem, however, though both the producing and marketing interests maintain their feeling of confidence that there will be a decided betterment shortly.

Stocks of soft coal in the hands of consumers are not exhausted. Probably only one-third of the reserves held in storage at the beginning of the year still remains yet users are unwilling to contract for their future requirements at the prices quoted by the operators.

The labor question grows more serious with the exodus of miners and the unwillingness of many of them to work full time. By next fall and winter the operations will be unable to work to more than 75 per cent. of full-time capacity, owing to the inadequate labor supply. In addition, it is doubtful if the railroads will be in a position to handle the full movement of coal and other freight this winter, for reasons that are obvious.

Operations are now running at about 50 per cent. or so, on an average, though some mines are working more than others. During the week ended June 7 nearly 9,000,000 net tons of soft coal were produced. The estimated production of bituminous coal for the calendar year to June 7 is 186,278,000 net tons compared to 247,196,000 net tons for the same period of 1918.

Complaint is general of the shortage of the domestic sizes of anthracite. Stove and egg, in the order named, are the sizes in greatest request, with chestnut running a close third. It is likely that by the end of the year consumers who are now so insistent on receiving these coals will have to resort to the use of different sizes, as it seems to be a foregone conclusion that production of the domestic grades of hard coal will not be able to catch up with the demand this year.

Steam coals move more slowly, and not much improvement is looked for until the winter sets in. Many operators are commencing to store these small coals at the mines against the time when consumers will be in the market for them.

The output of hard coal in the week ended June 7 totals 1,695,000 net tons. For the calendar year to June 7 the production of anthracite is estimated at 33,349,500 net tons, compared with 42,858,000 for the corresponding period of last year.

WEEKLY COAL PRODUCTION

The production of bituminous coal in the week ended June 7 is established at nearly 9,000,000 net tons, an increase over the week ended May 31, in which Memorial Day was observed as a holiday in some of the districts, of about 1,000,000 tons, and an increase over the week ended May 24 of 200,000 tons or 2.5 per cent. The production in the week ended June 7, 1919, was 3,635,000 tons or 29 per cent. less than in the corresponding week of 1918.

The average daily production per working day for the week ended June 7 was 1,488,000 tons compared with 1,456,000 tons in the week ended May 24. Reports of working time received from the operators for the week ended May 31 indicate that on the average over the country about one-half day in that week is to be considered as having been a holiday and that the average daily output in the week ended May 31 should be calculated on the basis of 5.5 working days. The estimated production of bituminous coal for the calendar year to June 7 is 186,278,000 tons compared with 247,196,000 tons for the same period of last year.

The production of anthracite in the week ended June 6 is estimated at 1,695,000 net tons compared with 1,285,000 net tons in the week ended May 31, and 1,656,000 in the week ended May 24. The production in the first week of June, 1918, was estimated at 2,034,000 net tons. The production for the calendar year to date is 33,349,500 net tons compared with 42,858,000 for the corresponding period of last year.

The production of beehive coke in the United States is estimated at 269,000 net tons for the week ended June 7, an increase compared with 264,500 tons in the week ended May 31, but below the output of 660,000 tons in the week ended June 8, 1918. Production of beehive coke this year to date is estimated at 8,750,000 tons compared with 13,207,000 tons in the same period of last year. All of the eastern districts report increases in the week ended June 7 compared with the last week in May, and the districts west of the Mississippi report decreases.

Bituminous coal dumped at lower lake ports in the week ended May 31, 1,004,753 net tons, was the record week for this year and the first week in which the million-ton mark was passed. The dumpings in the last week of May this year exceed the record for the last week of May, 1918, by more than 300,000 tons. The total coal forwarded from lower lake ports to the end of May is more than 5,000,000 tons and exceeds the movement of cargo coal last year by nearly three quarter million tons.

Atlantic Seaboard

BOSTON

No distinct change but undertone continues favorable. Reports of labor shortage are a factor in current situation. Postponement of navy's decision restricts volume of high-grade coals for open market. Other grades continue druggy. Dull market via New York and Philadelphia piers. Strike of trimmers at Norfolk interrupts shipments. Railroad purchases continue talk of the trade. Anthracite shipments disappointing.

Bituminous—The week has disclosed no significant change in market conditions. In most cases operators are still soliciting orders for June and July, although there are distinctly fewer contract offerings than a fortnight ago. Trade is light in practically every direction, but there is now a pronounced undertone that seems to forecast higher prices in the fall. Shippers have been arguing this for so long a period that not many buyers are impressed, but undeniably there has already begun a new spurt in buying for future needs. Large steam-users who have been marking time and trying coals have now come into the market for more or less comprehensive tonnages. The movement all-rail has not yet begun to show a material increase, but figures on July 1 should prove that there has been additional buying since June came in. The larger share of this increase in receipts will be for the high grades from Central Pennsylvania. Certain of these coals are now practically out of the market, and although medium and low grades are still to be had at prices well down to $2, it is expected that the generally improved state of the market will react on these as well before many weeks have elapsed.

Already there are reports of labor shortage in the region. At some operations where there has been a consistent effort for months to dispose of current output these efforts have now been relaxed because there are more spot orders on file than can conveniently be shipped. There are several instances where agencies in this territory have been obliged to cease selling for prompt shipment to permit the mines to catch up on production. When this happens in June it is a good sign and there are few in the trade who do not now predict freely that something like a "broad" market will prevail in October, if not before.

The Navy Department has not yet reached a decision, apparently, on the coals to be taken at New York under the proposals opened on May 29, and in consequence there are several shippers "in the air" as to the volume of commercial coal they will have available. As a matter of fact the delay, together with labor uncertainty, enables operators to withhold sales until a time when spot coal will almost certainly sell at a considerably higher level. Obviously, from now on, the quality grades from Central Pennsylvania will have sufficient demand for what coal can be mined. The Government is sure to get its quota, and coals on the accepted list will not go begging very much longer.

On the other hand, there are many producers of medium and poor grades who continue with difficulty to run their mines but two or three days a week. This territory is still being combed over for spot orders, and price inducements are being made as freely as at any time since January. Fairmont grades can be bought at $1.85@2 per net ton f.o.b. mines, and there is no dearth of Clearfield coal at $2.15 upward. The trend of buying here is toward the best coals for the money and there is bound to be only a narrow market for high-volatile or high-ash coals until the better grades cease to be offered. Meanwhile, the demand is certain to be inactive.

At the New York piers the demand is also dull and lifeless. Aside from bunker-

ing the tonnage dumped is light and relatively only a small volume is moving either on Long Island Sound or to Boston and the points eastward. At Philadelphia the movement is practically confined to locomotive fuel for such roads as the Maine Central, the Bangor & Aroostook, Canadian Pacific and others. Eastern dealers are not sparing any space from anthracite, under present conditions, and no shippers dare send coal to the Philadelphia piers without orders and marine transportation in hand. The result is that for the most part coal is coming down from the mines only on special order. From Philadelphia it is now practically impossible to secure Reading barges for commercial bituminous, so large a proportion of the fleet having been allocated to the railroads for engine fuel.

The trimmers' strike at Norfolk has been the outstanding fact in Pocahontas and New River distribution the past week. This has meant practically a cessation of loading for several days and in other times would have meant serious interruption in the flow of coal. The agencies have done what they could to shift steamers to other piers and they have also discontinued chartering steamers and barges on a trip-to-trip basis. There has been practically no effect on the situation here, for the southern coals this year are cutting only a very light figure in the New England market.

The more that is learned about railroad purchases in this territory the greater is the amazement that regular channels of supply over long periods have been utterly discarded. Instead, contracts have been placed with a large number of shippers, many of them jobbers in New York and Philadelphia, who are little known in this market and have their experience mostly ahead of them. The remote districts were canvassed in the effort to get bids low enough to suit the controlling authority and it remains to be seen whether the outcome will really cost less than had the coal been purchased of customary sources.

Current quotations on bituminous at wholesale range about as follows:

	Clearfields	Cambrias and Somersets
F.o.b. mines, net tons	$2.15@2.75	$2.75@3.35
F.o.b. Philadelphia, gross tons	4.27@4.95	4.95@5.50
F.o.b. New York, gross tons	4.62@5.29	5.29@5.85
Alongside Boston (water coal), gross tons	6.10@6.85	6.90@7.35

Georges Creek is quoted at $3.20 per net ton f.o.b. mines.

Pocahontas and New River are being quoted at $5.04@5.24 per gross ton f.o.b. Norfolk and Newport News, Va. Alongside Boston the same grades are being offered at a range of from $7.24@7.44, and on cars Boston and Providence at from $7.50@7.90 per gross ton, the latter being the contract price f.o.b. cars for deliveries to April 1.

Anthracite—The first half of June has proved most disappointing to New England dealers. Instead of shipments being increased they have seemed regularly to diminish, especially on egg and stove, the sizes in greatest demand. There has also been increasing anxiety over the very heavy proportion of barges being used to carry bituminous. Shippers who have regularly supplied the market are turning the coal in other directions and chartering their barges wherever an order can be had. The Reading fleet, upon which a large number of retailers have always relied, is bringing forward less anthracite than ever, and as the season advances they are beginning to see the full force of the decree that these barges must carry a heavy tonnage of railroad fuel. The same functionaries who experimented with the movement of these barges from Port Reading instead of from Port Richmond are responsible for this further interference with one of New England's most dependable avenues of supply.

NEW YORK

Dealers complain of lack of domestic coals. Egg, stove and chestnut becoming scarcer and the trade looks for greater shortage as season advances. Shipments to this market continue on even basis. All sections of the country receiving anthracite. Steam coals drug the market and prices are easy. Bituminous tidewater market soft but the trade retains its confidence that business will improve. Line trade picking up and some coals are quoted higher than last week.

Anthracite—Everywhere is heard the complaint of the lack of domestic coals, and there is no reason to expect that they will diminish as the season advances. There has been no improvement in the situation although the shipments of anthracite for May show a substantial increase over those for April, and this in spite of the fact that the mines were idle on several holidays.

Shipments to this market continue on about the same basis as for the past several weeks. This is due, no doubt, to the desire of the trade to take care of the outlying districts. It must also be remembered that the sections of the country that did not receive anthracite during the war period by order of the Fuel Administration are now taking their usual prewar tonnage. Considerable coal is being sent into Canada as well as westward. It is reported that some Canadian dealers have offered premiums for quick shipments.

The call for stove, egg and chestnut, in the order named, keeps up. There is a decided shortage of the two first-named sizes and dealers are urging their customers to substitute some of the other sizes. While there has not been much willingness displayed in agreeing to the suggestion, it is likely to be generally accepted this fall unless production picks up considerably between now and the time to start furnace fires. During the war there was considerable substitution of sizes and the consumer learned much about burning the various sizes of coal.

This market obtained a few hundred cars of anthracite more last week than the previous week, according to the report of dumpings at the local railroad docks. During the week ended June 13 there were dumped 5691 cars as compared with 5380 cars the previous week, an increase of 311 cars. On June 13 there were on hand 3112 cars of anthracite as against 3007 cars on June 6, an increase of 105 cars.

Disposal of the so-called Independent product is an easy matter these days. It is not a question of salesmanship as the orders come into the offices. Considerable of these coals are bringing premiums ranging all the way to 50c. per ton, according to current reports, but some orders taken early in the year are being filled at the prices current at that time.

The steam coals are becoming a drug on the market. They are extremely weak, with small opportunity of the market showing much improvement until cold weather. There is a belief that those operators who have not already started will soon commence the storing of these coals at the mines. The larger companies with storage places have already stored considerable.

Current quotations, white ash, per gross ton at the mines, f.o.b. tidewater, at the lower ports, are as follows:

	Mine	Company Circular
Broken	$5.95	$7.80
Egg	6.05	7.90
Stove	6.30	8.15
Chestnut	6.40	8.25
Pea	5 00	6.75
Buckwheat	3.40	5.15
Rice	2.75	4.50
Barley	2.25	4.00

Bituminous—The market is soft, yet the trade maintains its confidence that there will be a decided improvement shortly. Evidences of this change for the better come from salesmen who have visited the inland dealers. They report buying better and a strengthening of prices. So far as this tidewater market goes, there is a decided dullness, with quotations on the various pools far from normal. Movement is slow, many idle boats lying in the harbor.

There were not so many loaded cars at the various railroad docks on June 13 as on the corresponding day of the previous week, the reports showing 4394 cars on hand as against 4664 cars on June 6, a decrease of 270 cars, while for the same period there was a falling off of cars dumped, the reports showing 5748 cars dumped as compared with 6511 cars the previous week, a decrease of 763 cars.

Shippers of coal from certain districts are refusing quotations, asking the prospective buyer for offers. This tends to show that the miners of these coals are not over-supplied with free coals of the better quality and it may also show their hopes in the future.

Handlers of bunker coals are complaining of the loss of business through the absence of ample pier facilities. In the last days of last week there were nearly 50 vessels lying in the harbor waiting for piers at which they could tie up. This lack of piers, it is claimed, has caused many owners of vessels to send their boats to Baltimore and other shipping ports along the coast. Because of this the coal trade here has lost considerable bunker business, some of which will never return to this market.

Quotations for Fairmont and Westmoreland coals are stronger than for the past few weeks and shippers report many more inquiries.

Reports from the mining regions show that labor is in better shape and that because of the increase of orders along the line the mines are working about 65 per cent.

With conditions showing a gradual improvement, Central Pennsylvania miners look for a change in that section.

Quotations on the various coals are about as follows:

	Spot	Contract
South Forks	$2.90@$3.25	$2.95@$3.50
Cambria County (good)	2.75@ 2.95	2.95@ 3.25
Clearfield County (good)	2.50@ 2.75	2.80@ 2.95
Reynoldsville	2.50@ 2.75	2.75@ 2.95
Quemahoning	2.65@ 2.85	2.95@ 3.10
Somerset County (best)	2.65@ 2.85	2.95@ 3.10
Somerset County (poor)	2.00@ 2.35	2.50@ 2.75
Western Maryland	2.25@ 2.50	2.50@ 2.75
Fairmont	2.00@ 2.25	2.35@ 2.60
Latrobe	2.10@ 2.25	2.25@ 2.40
Greensburg	2.25@ 2.35	2.35@ 2.60
Westmoreland ¾-in.	2.60@ 2.75	2.75@ 3.00
Westmoreland run-of-mine	2.35@ 2.60	2.60@ 2.85

PHILADELPHIA

Anthracite demand gains in volume. Orders unfilled. Demand for family sizes expected to run all summer. Individual prices advanced. Increases cause concern. Consumer demand dwindles. Stove hard to get, egg scarce, chestnut in moderate supply, and pea well cared for. Buckwheat shows strength. Rice and barley unimproved. Bituminous unchanged. Good grades strong. Prices well maintained. Little contracting. Fair spot trade.

Anthracite—Real summer weather fails to hold back the anthracite trade. This is particularly noticeable from the producing end, where all companies have more orders on their books than they can fill for weeks. While not at all serious at this time, there can be no doubt nevertheless that all mines could use more inside men. For outside work there is little difficulty in procuring men. Yet despite the efforts of the operators they are unable to get production up to the point that the present situation justifies, and even now forecasts are being made as to what will happen next fall if the operating department is unable to get out the tonnage somewhat near the maximum established during the war.

As to the present situation on family sizes, all producers are extremely confident that the demand for the larger sizes will continue indefinitely. The calls upon them continue from all markets and shippers point out that at the present rate of production it will be impossible to satisfy them during the coming summer.

The fact that some operators are charging premiums of from 15c. to 30c. per ton above company circular tells a tale. As a matter of fact, several of the independents have come out with announcements to their regular trade of an advance of 10c. per ton above circular, and in some cases even 20c. The impression seems to prevail now that the individual operators will all be at least 75c. a ton above company prices by the time frost arrives, if not sooner. In this connection we have in mind one large operation whose production is sold through a middle house, and the coal is netting the producers 15c. above the recognized circular. In other years this coal was often sold in block tonnages in April or May with the prices of those months protected up to September or October, and the agents' commissions were paid out of those rates. For occasional blocks of coal we know that some houses are refusing offers of 50c. per ton advance over current circular, and that more conservative operators are criticizing those who are inclined to accept business at fancy figures.

Locally the market continues short, but the dealers report a rapid falling off in new business. Some retailers when asked to make an estimate stated they do not believe that more than 70 per cent. of the consumers accustomed to buy at this time of the year have as yet placed their orders. One of the very largest retailers placed his estimate as low as 60 per cent. Dealers generally report lack of interest on the part of the householders, particularly the small buyers, and express their determination to continue all summer their efforts to

fill their bins before fall, by which time it is expected the scramble for coal will be renewed. The one great drawback to this plan is that most of the small consumers, being house renters, are not at all certain as to where they are going to live by the time coal-burning weather arrives again. Certainly the outlook for the future is not at all hopeful, and most representative dealers express the belief that only a mild winter will prevent great inconvenience and higher prices.

Egg continues extremely short and really cannot become plentiful, because the New England market and the South in the vicinity of Baltimore and Washington are calling for enormous tonnages. Stove appears positively hopeless, with most dealers entirely out of it; certainly few have what could be called a stock, and the dealers here are tormenting the shippers for it. All shipping offices say the demand from every market is equally great. Chestnut is very far from weak, but is in greater supply than either stove or egg. Shippers say that it is not likely that the demand from western markets can be filled all summer. We have even heard of first-class washery nut bringing full price. Pea remains in very fair shape and shippers report orders in hand for several weeks in advance. We know of one individual house that has actually refused to take on any new business for this size. Of course, the pea that the dealers take in is not being delivered, but is being stored away for winter delivery, as has been their custom for years, most dealers having given up hopes of filling this storage space with chestnut.

The buckwheat market has strengthened during the past week. The poorer grades are being offered from $2.65 to $2.85, while $3.25 to $3.40 is being asked for first-class coals. The big companies are considering no bulk business at less than $3.40, and we are inclined to the opinion that no first-class buckwheat is being sold at reduced prices for shipment beyond sixty or ninety days. Rice shows little strength and orders are accepted around $2.50 for spot shipment. Heavy tonnages are going into the big storage yards while the smaller operators are piling it up at the mines. The same practically holds good for barley, which has been offered at $1.35 recently. However, shippers are taking a cheerful attitude on the situation, and one of the very largest houses advised us they look for greatly improved conditions in all junior sizes within sixty or ninety days, particularly as the outlook for increased steel production is so promising.

Bituminous—The soft-coal situation is almost colorless, if we except the tendency of the high-grade coals to grow scarcer, with the consequent well-held prices for such grades. Cheap coals continue plentiful, and we have heard of quotations on occasional lots as low as $1.80.

Consumers generally seem to be stirring themselves and endeavoring to place themselves in position to buy at the most favorable prices. Many of them want to barter for fuel somewhat on the basis of railroad fuel prices, which are published and are known by all interested in fuel. Of course, it is beyond all reason to sell commercial coal at anything near such prices, especially fine grades of coal.

Contracting seems to have reached almost the minimum for the season, with the bulk of transactions being on a spot basis recently.

BALTIMORE

Export trade shows material increase. Domestic trade inactive. Rumors of large combine.

Although domestic business has been light during the week, the export situation has gone ahead remarkably fast and to such an extent that the indications are that June will be a record month for coal exporting. During the first week of June 40,169 tons cargo and 4505 tons bunker left this port, and within the next two weeks allocation of steamers from this port show that 42 vessels will carry coal to foreign ports. The 42 vessels are the share of 56 steamers that have been allocated for foreign business from this port by the United States Shipping Board. But one steamer will go to South America, the others will be distributed as follows: Gothenberg, 17; Rotterdam, 16; Stockholm, 5; and Genoa, 3. The 56 vessels will carry 280,000 tons from this port and it is estimated that the share of the vessels carrying coal will approximate 200,000. The allocation of coal is expected to be increased materially before the month is past, which makes it appear to observers that this will be a real month's business for the export coal men here.

Despite this heavy shipment of coals there is still little foreign contracting, although the air is full of nibbling with no real bites. The only contracting reported here is that of the 3,000,000 tons for Italy, which was made about two weeks ago.

Failure of any real demand for coals keeps the domestic market inactive. At many points where formerly large tonnages of bituminous coal were used, oil is now being purchased as fuel. Dealers estimate that at least a quarter of a million of tons of coal less will be required in industries here because of the installing of oil-burning boilers. Bethlehem Steel Co. use coal only in the coke ovens, while the Standard Oil Co., United States Industrial Alcohol Co. and other plants all use oil in place of coal.

The best grade of coals at spot brought $2.75 and down to $2.50, while the medium grade fuels sold around $2.30, with no one desiring the low-grade fuels, which went as low as $1.90. Baltimore City has 8000 tons of bituminous, which was bought during the war, but which various departments are objecting to and declining to use. There is some talk of the city selling it on the open market.

The anthracite dealers are still worrying along with low receipts. Large dealers are worse off than the small ones because the equipment of the big firms is idle a great part of the time. Householders will have at least a 25c. increase tacked on July 1, and this may go higher. The belief is general that the independent operators will attempt to force up the price, and during the week one dealer was approached by an independent operator, who offered to furnish all the coal the dealer wanted at a 65c. premium per ton. There is a rumor that there will be a combination of a half dozen firms into one large corporation. The plans provide for a center office downtown with distributing points in all sections of the city. This is the second time within less than half a dozen years that this report has been made. It fell through previously because of inflated values placed by some of the firms on their business. This year the belief is strong that it is likely to be consummated.

Lake Markets

PITTSBURGH

Consumers still unwilling to contract. Labor shortage threatens, also railroad difficulty, next fall and winter. Market prices unchanged.

Line consumers do not show any greater disposition to take hold in the matter of contracting for coal. While operators are talking strongly of higher prices late in the year, there is reason to suspect they would prefer consumers to place contract at prices determined by operators. Stocks in the hands of consumers are not yet exhausted, though probably at least two-thirds of the stocks held at the beginning of the year are gone. Operators contend that consumers should carry not only the stocks now held but even large stocks on the ground that it is very improbable that there can be capacity operation of the coal mines of the district next winter, and such an operation would be required to supply the industries if they have full activity as they seem to expect.

The labor situation grows more serious with the exodus of miners and the unwillingness to work full time. Some operators express doubts whether, with all other conditions favorable, the labor supply would permit of more than a 75 per cent. operation by next fall and winter. Apart from this is the railroad situation, it being doubtful whether the railroads in their present condition could handle a full movement of coal and other freight even if the winter were milder than usual. Operations are now running at 50 per cent. or a trifle more, on an average, but some mines are running much better than others.

For prompt and early deliveries prices are as formerly quoted: Best grades gas coal: Slack, $1.65@1.85; mine-run, $2.35; prepared sizes, $2.60@2.70; Steam: Slack, $1.50@1.70; mine-run, $1.90@2.35, per net ton at mine, Pittsburgh district. Steam mine-run on contract to the end of the coal year is very firm at $2.35 as minimum, and with higher prices predicted.

BUFFALO

Slight improvement in bituminous. Not much stir looked for right away. Industries do not move. Anthracite mining still slow. Demand heavy. Lake shipments keep up fairly well, though not as great as desired.

Bituminous—The demand may be said to increase slightly, but there is nothing looking like a stir in sight. The volume of manufacturing is not large, and it is so disturbed by labor troubles that even an intended amount of output is often not reached. This affects the coal trade directly and postpones the day of recovery. That it is not far off is agreed. In fact the operator especially, and the jobber to a certain extent, is optimistic and will have it no other way than that we are on the eve of a rapid movement of bituminous coal.

The Buffalo jobber is not enthusiastic. Too many complications keep coming up for business to return to the normal just yet. Traveling salesmen go out much as formerly and good ones make sales, but it would be useless for a new man to try the road now. He would make no profits. The consumer is still looking for lower prices.

The mines have already made more concessions than they should, and all that they have accomplished is to cut down their narrow margin of profit. They have not increased the general volume of business and it is doubtful if in the long run they have increased their own. Quotations remain at $4.55 for thin-vein Allegheny Valley, all sizes; $4.45 for Pittsburgh and No. 8 lump; $4.30 for three-quarter; $4.05 for mine-run and $3.65 for all slack, per net ton, f.o.b. Buffalo.

Anthracite—The trade is still short of coal. No improvement is in sight, unless it be that the local demand is lighter. More coal has been bought so far by consumers than usual, and that would seem to account for the continual report of shortage but for the mine report, as shown by the Government bulletins, that mining is less now than it has been in six years. If the consumer has learned to economize and use substitutes enough to make up for this shortage, he may get through the winter safely; but it is to be feared that he has not, in which case the dependence must be on another mild winter.

The June prices of anthracite are as follows:

	F.o.b. Cars, Gross Tons	At Curb Net Tons
Grate	$8 55	$10 20
Egg	8 65	10 40
Stove	8 90	10 60
Chestnut	9 90	10 70
Pea	7 20	9 15
Buckwheat	5 70	7.75

Lake shipments keep up only fairly well. The demand is too general and too heavy for shippers to get as much coal for the lakes as they would like. The amount loaded for the week was 86,900 net tons, of which 38,600 tons cleared for Chicago, 6000 tons for Green Bay, 3800 tons for Racine, 18,200 tons for Duluth and Superior, 12,000 tons for Fort William, 8300 tons for Hubbell.

Freight rates remain quiet at 80c. to Racine, 50c. for Chicago and Green Bay, 42½c. for Duluth, Fort William and Hubbell.

CLEVELAND

Prices are stiffening, with Pocahontas and anthracite increasingly difficult to obtain. Operators are more inclined to shove up their quotations on slack and mine-run, with slack more easy now to dispose of. Upper lake dock operators are taking all the bituminous coal they can obtain, although coal is not moving so freely off the upper lake docks.

Bituminous—Business appears to be opening up in all directions. The iron and steel industry—the largest single user of coal in northern Ohio—is rapidly getting under way, and much pig iron and all varieties of finished material are being sold in big tonnages. The prediction that Aug. 1 will see the industry at 100 per cent. operations still holds, and each succeeding week sees its coal and coke consumption increasing. Purchasing agents of the larger mills now are waking up to the situation and suggestions that they had better cover for the remainder of the year are having effect. Some operators believe that within two weeks many of the larger steam-coal consumers will have placed their contracts.

Slack is much firmer in price, and while some still can be had at $1.90, it is believed $2 more nearly represents the market. Not much will be sold at that figure, is the prediction. Some operators look for slack to go to at least $2.50 in the early part of the winter. Mine-run and prepared sizes are also reflecting improved conditions, and mine-run is now bringing $2.10 and up at the mines, with most of it averaging between $2 and $2.10. With each succeeding week showing production far behind last year, coal interests can see nothing but enormous demand coming out in the last half year, with a runaway market the obvious result. The labor situation at southern and eastern Ohio mines continues bad, and most operations can do no better than 55 to 60 per cent. of capacity with their present forces. This situation is one that will grow much worse before it becomes better, it is feared.

While retail dealers have been able to obtain an adequate supply of domestic bituminous, they are complaining of the difficulty in meeting the demand for anthracite and Pocahontas. The coarser grades of Pocahontas seem especially scarce. Domestic demand keeps far ahead of the normal summer business. Some dealers, it develops, have not yet increased their anthracite prices, but on July 1 they plan a 30c. advance in order to catch up with the procession.

Lake Trade—Lake Erie car dumpers continue to handle about 900,000 tons of bituminous coal weekly, making the monthly totals under 4,000,000 tons. In May, the lake carriers took 3,821,295 tons of bituminous for the head of the lakes. This week the docks are dumping from 3000 to 3200 cars daily. Coal is reported not moving so freely off upper lake docks as might be hoped. Demand for lake coal has not abated, and operators are finding a ready market for every car they dispatch to Lake Erie ports.

Price of coal per net ton delivered in Cleveland, is:

Anthracite:	
Egg	$10.85@11.05
Chestnut	11.15@11.35
Grate	11.05
Stove	11.05@11.25
Pocahontas:	
Forked	9.00
Lump	8.25
Mine-run	7.20
Domestic Bituminous:	
West Virginia splint	7.75@ 8.00
No. 8 Pittsburgh	6.10@ 6.35
Massillon lump	7.30@ 7.40
Steam Coal:	
No. 6 slack	4.20@ 4.40
No. 8 slack	4.70@ 4.95
Youghiogheny slack	4.85@ 5.15
No. 8 ¾-in.	5.40@ 5.55
No. 6 mine-run	4.40@ 4.50
No. 8 mine-run	4.80@ 4.95

DETROIT

Steam-coal buyers are still maintaining a waiting attitude, though a fair demand for domestic stock is reported.

Bituminous—Realization of the advantages of buying their coal supply at present apparently has not yet become general among the Detroit consumers of steam coal. Jobbers and wholesalers say there is only a small volume of business being transacted and that buyers are continuing the attitude of aloofness that has been characteristic of the local situation for some weeks.

It is a theory among some of the jobbers that the users of steam coal are waiting in the expectation of cheaper coal coming into the market. Jobbers insist such a development is highly improbable and explain that the delay in releasing orders will mean an accumulation of business later that will tend to produce an advance in prices, when the buying movement sets in, due to the lack of mine reserves and limitations on output imposed by shortage of labor.

Though there is apparently some increase in amount of free coal on tracks, shipments are said to consist largely of slack and fine coal for which there seems little demand, the result being a weakening of prices. While quotations on Ohio slack are reported as $1.50 and on the West Virginia product at $1.85 to $2 a net ton at the mines, jobbers say there are rumors of sales having been made around $1.25 and even lower, in the effort to escape the heavy demurrage accruals.

Mine-run is quoted at $2 for Ohio stock and $2.10 to $2.25 for West Virginia coal, while smokeless holds around $2.75 to $3. Hocking domestic lump is reported selling at about $2.50, with West Virginia gas and splint lump at $2.75 and three-quarter lump at $2.50.

Anthracite—Extremely hot weather during the last few days has somewhat reduced the inquiry for anthracite. Retailers are making an active campaign to encourage early distribution among household consumers.

Lake Trade—Shipments over the lake routes are holding considerable volume and for the week ending June 7 a record for the season was attained, with the loading of 1,122,322 tons of cargo and 46 007 tons of fuel coal, a total of 1,168,329 tons. Toledo, Ashtabula and Lorain, in the order named, were the heaviest shippers.

COLUMBUS

There is increasing evidence of activity in the Ohio coal trade. Inquiries for steam grades are more numerous, indicating a disposition on the part of big users to buy. Domestic grades are stronger and the lake trade is progressing satisfactorily. Prices are still uncertain.

The best feature of the Ohio coal trade during the past week is the increase in the domestic demand. Retailers are gradually increasing their stocks in order to take care of the expected rush in business when the stocking-up season opens. Retail stocks are not large in any section, and consequently there is a general movement to buy. The large part of the orders booked are for the fancy grades, such as Pocahontas and West Virginia splints. Kentucky grades are also in better demand for stocking purposes. As Hocking is not stocked a great deal at this time, there is no important buying movement. Prices for the better grades of lump range higher and all recent advances are well maintained. Pocahontas lump is selling between $4.50 and $5 at the mines, and is scarce at that.

The steam trade is also showing signs of awakening. As industrial conditions slowly improve there is a better demand for steam sizes. This has been noticeable during the past week and the result has been to diminish the over-supply of screenings which has been a drug on the market. But Screenings are still cheap and some extremely low quotations are heard. Iron and steel plants are slowly resuming and are buying a large tonnage for fuel purposes. Rubber factories have about used up their reserve stocks and will soon be in the market.

Production is better in practically all of the Ohio fields. This is most noticeable in the eastern Ohio field, where the output is now estimated at 80 per cent. of normal. In the Hocking Valley and Pomeroy Bend fields the output is between 65 and 70 per cent. and gradually increasing. Other fields are showing up fairly well with prospects of an increase within the coming six months.

The Lake trade is showing considerable activity. Loadings at the lower lake docks are good, and it is claimed that the movement from Ohio ports to date is ahead of last year's shipments. Vessels are plentiful and chartering is going on fairly well. Owing to unsettled prices, contracting for Lake tonnage is not being done on a large scale.

Retail prices delivered in Columbus are:

Hocking lump	$5.50 to $5.75
Pomeroy Bend lump	5.95
Island Creek	6.25
White ash	6.25
Splints, lump	6.00 to 6.50
Kentucky Wheeling Creek	6.75
Semi-smokeless	6.75
Pocahontas	7.00 to 7.25

LOUISVILLE

Block coal in good demand, with operators forcing prices upward to check demand. Screenings hard to dispose of, resulting in dumping at mines in many instances.

The demand for block coal has been so keen since domestic consumers started stocking, and retailers began buying heavily, that some mines are forcing prices up on all new business, owing to the fact that in handling additional block business they are unable to dispose of the accumulated screenings, which have to be dumped at the mine. This will mean rehandling, with the result that better prices must be had to take care of the additional costs. A fair volume of block business can be handled, and screenings sold on a spot market, but with increased block the operator is helpless in the matter of forcing out his screenings, as the market cannot absorb the supply.

A number of operators are forcing retailers to take a car or two of screenings with every car of block in order to lessen the burden. The coal is screened for the retailer, relieving him of the difficulty of hand-forking, and it is felt that under existing conditions he should be willing to aid the operator.

Eastern Kentucky operating conditions are fair, as there is a big demand for block, a fair demand from the lake region, and an increasing demand from byproducts, gas and other plants. Little coal is moving south for bunkering, although some coal is going to textile plants. However, steel and iron plants, cement manufacturers, brick plants and many others are buying small tonnages.

Western Kentucky is hard hit the way things are now going. Owing to the fact that freight rates favor eastern Kentucky coals, and due to the higher grades of these coals that are selling at low prices, western Kentucky has not a large or ready market, but operators are unable to cut prices much more because of the high overhead. The result is that mines are operating one to two days a week, with many of them down. This makes it difficult to hold labor, which is shifting to the eastern Kentucky fields, where the supply is not equal to the demand.

The car supply is becoming a little short, and is giving many operators uneasiness. The heavy movement to the Northwest and lakes this year has kept many cars in transit for long intervals, and considering the fact that there are several hundred cars moving out daily, the outlook is not especially promising.

Quotations are: Eastern Kentucky, block, $3.25@3.50; mine-run, $1.90@2.40; nut and slack, $1.50@2. Western Kentucky, lump, $2.25@2.55; mine-run, $1.85@2.10; nut and slack, $1.75@1.85; screenings, $1.45@1.75, according to size.

BIRMINGHAM

Steam market remains inactive, little spot business being booked. Lump coal very strong and hard to get. Supply very much restricted on account of lack of steam orders at the mines.

The past week has shown no improvement in the demand on this district for steam coal. A large number of railroad contracts expire June 30 and will come up for renewal in the next week or so, though no action has thus far been taken by the rail lines to provide for the fuel requirements for the next twelve months as covered by the expiring agreements. Commercial trade will most likely be favorably affected by the closing of contracts for the needs of the railroads.

Domestic dealers are finding it difficult to secure the desired amount of lump coal, and the scarcity of domestic sizes is such that only now and then can a car be picked up in the spot market. With an improvement in the steam trade this condition will be relieved to some extent, but coal men predict that the shortage this winter will be more keenly felt than in any previous years. Consumers are not buying heavily at this time but nevertheless dealers have not been able to accumulate much coal on their yards.

Some increase in production will be shown by the furnace companies due to the placing of several stacks in commission which have been out of blast for some months on account of the dull iron market, which is now showing gradual improvement.

Coke

CONNELLSVILLE

Contract negotiations for furnace coke, with uncertainty as to outcome. Some furnaces may switch to byproduct coke. Prompt coke firmer.

If the coke market follows the views of Connellsville coke operators as to contracts for the second half of the year it is going to be a very strong one, but the matter is not decided yet. What may be considered negotiations on second half furnace coke have been under way, but they have consisted chiefly in operators giving their views to consumers, in a few cases perhaps naming flat prices, but in the majority of cases proposing sliding scale contracts of various forms. The sanguine feeling pervading the ranks of operators is illustrated by the case of one, who is unwilling to sell for the whole half year but hopes to find a customer for the third quarter. Since the expectation is that pig

iron production will increase up to the close of the year, it is the latter portion of the half year that consumers would be particularly interested in covering against, not the third quarter.

Some eastern Pennsylvania furnaces have been heard from with a statement that if they cannot buy Connellsville coke for the half year at about $3.85 they will not buy it at all, but will depend upon byproduct coke made in the East. They are now offered Bethlehem coke on an iron-bound contract as to deliveries, to offset the operating difficulty the Bethlehem company had some time ago, and there is also the Midvale operation, which is expected to be completed next month. Connellsville operators have no thought of selling even at $4 as a flat price for the half year. Ratio contracts of various sorts are proposed, one being on a 6 to 1 basis—that is, if basic pig iron is $25, valley, which is the approximate price now, the coke would be priced at $4.17. There are various details, relating to maximum and minimum prices and other limitations.

The spot furnace coke market is firmer, it being altogether exceptional for any coke to be available at under $4, while foundry coke readily brings $4.50 for very ordinary grades, and $4.75 and $5 for the better grades. There is nothing very definite as to foundry coke contract prices.

We quote spot and prompt coke at $4 for furnace and $4.50@5 for foundry, per net ton at ovens.

The "Courier" reports production in the Connellsville and Lower Connellsville regions in the week ended June 7 at 117,655 tons, an increase of 6320 tons.

Buffalo—The trade does not improve much. Iron ore comes in slowly by lake and the furnaces are running on slow time. Reports of improvement are not confirmed. Prices remain at $7.25 to $7.50 for 72-hour Connellsville foundry, $6.60 for 48-hour furnace and $6.10 for off grades. Some bituminous shippers are selling crushed sizes for fuel at about foundry prices. They report no sale for breeze coke.

Middle Western

GENERAL REVIEW

All branches of Middle West coal industry not so optimistic. Screenings piling up. Intimation that Government control of coal may again be inaugurated. Large consolidation in Franklin county field.

Operators and jobbers alike report a decrease in business for the weekly period just ended. This lessening of the current demand appears to be general, as practically all of our producing fields are affected, and steam sizes, rather than domestic and railroad egg and lump. The market on screenings is especially weak, and a number of operators have found it well nigh impossible to move their surplus on this size. It is said that one producing field alone has piled in storage over 125,000 tons, as the operators in that district prefer to store their coal rather than sacrifice it on the open market.

One of the reasons for surplus screenings is that considerable lump and egg is moving on railroad orders, and as the operators having railroad shipments must forward coal regularly, it means an accumulation of screenings, which must be moved from day to day. Another reason why the screenings market is weak is because one of the biggest users of steam coal in this territory—public utility people—are still engaged in burning coal they have had in storage. As a result of the conditions mentioned, the screenings market has had a bad week, Southern Illinois 2 in. screenings selling as low as $1.75 mines, and good Indiana screenings as low as $1.50 or perhaps in some cases even less.

The market on prepared sizes—for instance, either lump, egg or nut—continues strong; in fact many producers are behind on their orders. This scarcity on prepared coal is because of recent railroad purchases, as well as a strong demand on the part of the retailers for domestic coal.

Dr. Garfield, in a speech on the Pacific Coast, advised the public that the coal industry would soon be back under Federal control. This came rather as a surprise to the operators, and we believe an unwelcome one, as a whole. The operators feel that the Government restricted them perhaps too closely when there was an opportunity to show a profit, and then, when a chance came for the Government to help the industry, in the railroad matter, for instance, the operators were left high and dry, to shift for themselves.

The coal trade was not surprised to learn that another big consolidation had taken place in the Franklin County, Ill., field. It seems that the Chicago, Wilmington and Franklin Coal Co. has taken over both the Hart Williams mine and the Pyrolite mine, each located in the vicinity of Benton. There is a tendency, especially in Southern Illinois, to merge interests, and place most of the coal properties in strong hands. These developments are perfectly logical, and meet with general approval, as it means a saving to the public. Take for example selling costs. Formerly, each mine in the Franklin County district maintained at least two sales offices, say one in Chicago and another in St. Louis or Minneapolis. As the situation is now, the whole field is represented by three or four large companies, and instead of over a dozen sales offices there are but a third of that number.

The feeling expressed by operators this week is not quite as optimistic as heretofore. The general idea is that screenings and steam coals, with the exception of railroad coal, will continue dull and a problem for at least the next 90 days. Industrial activities have not developed as was predicted, although there are those who predict during the fall and winter months a demand that will prove greater than the supply.

CHICAGO

Better demand for coal and dealers are stocking Eastern coals. Premiums offered for anthracite shipments.

The "Buy your coal early" campaign started by local papers and local coal men a few weeks ago is already beginning to show results. Operators and jobbers from all of the producing fields report a strong domestic demand from Chicago. The steam market continues to lag with small hope of any immediate betterment.

Strange to say, some of our local retailers appear to have profited by the distressing conditions they have been forced to undergo during the past two years. We are glad to say that a few of the more up-to-date and aggressive dealers are now stocking coal. Of course, they are stocking Eastern coal—anthracite, Pocahontas and eastern Kentucky at this time—but they soon will begin laying in a reserve supply of high-grade domestic coal from our own fields in Illinois and Indiana.

The householder is also showing signs of interest, and local retailers report a decided betterment in current orders. Anthracite is in such demand that dealers are offering independent operators 25c. per ton or more premium on prompt shipments.

MILWAUKEE

Coal rules quiet and steady, and dealers report increasing deliveries. Receipts by lake continue liberal.

Coal dealers in Milwaukee report a quiet market, with slightly increasing business. The June advance of 10c. per ton on all grades of anthracite except buckwheat is being publicly protested, and the Milwaukee Association of Commerce, an organization representing every business interest in the city, announces that it will vigorously oppose any further increase in the price of coal, on the ground that it is sufficiently high now and that Milwaukee, with excellent water transportation facilities, should not be compelled to pay exorbitant rates for this class of fuel.

Large users of Illinois and Indiana coal during the war period are gradually getting back to the eastern product. The Central Coal Co., which handled Illinois coal exclusively for the past three years, has put in nearly 75,000 tons of eastern bituminous thus far this season.

Coal is arriving freely by lake, the volume received thus far since the opening of navigation being considerably in excess of last year's record. Up to date 186,153 tons of anthracite and 892,506 tons of bituminous coal have been handled over the docks, as against 124,061 tons of the former and 531,480 tons of the latter during the same period last year.

The City of Milwaukee is advertising for bids on 60,000 tons of coal for public institutions during the coming winter.

ST. LOUIS

Situation remains quiet and the expected call for coal the middle of June has not as yet materialized. Coal in the Standard district still going below cost and no demand for either steam or domestic. In the high-grade field domestic is moving fairly well, while steam sizes are blocking the mine.

The situation is not what it was expected it would be by this time, though conditions are somewhat better. The public still seems to expect a reduction in the price of coal despite reports that the country is behind in its tonnage.

Locally there is a little anthracite and smokeless domestic moving. On the other kinds of fuel there is nothing coming in to speak of, except a little coal from the Standard and Mt. Olive fields. Coke is a drug on the market, except that which is being put in storage by the dealers. There is some threshing coal moving, but not the tonnage that was expected.

Steam locally is at a standstill, and the same condition prevails in the country districts. There is nothing at all to warrant any improvement unless something out of the ordinary happens in connection with the domestic business.

In the Standard district some little coal is moving into St. Louis for steam. Most of the tonnage is going to railroads and some to Chicago. The Chicago tonnage is extremely light and the condition in this field is deplorable at this time, with coal selling below cost and no market for it.

In the Mt. Olive field conditions are considerably better. Some railroad coal moves here and the bulk of the tonnage moves to Chicago and the Northwest.

In the Carterville field of Williamson and Franklin County, as well as in the Du Quoin field in Perry County, the situation is not all that it could be. Steam sizes are long and in some instances the mines are shut down on account of screenings and the smaller sizes of steam coal. Many mines still continue to pile screenings and steam sizes on the ground. Some of the mines are not working at all, and others are only on half time. The car supply is good and transportation is standing up well.

COAL AGE

Volume 15 New York, June 26, 1919 Number 26

New Tools Require New Training

By R. Dawson Hall

UNFORTUNATELY, the early history of coal-mining is exercising undue influence on the elementary technical education of present-day mining men. Early mining operations were quite crude, and there was little of a scientific nature to learn about the subject except what was taught under the heads, Chemistry of Gases and Principles of Ventilation. With little or no machinery, no fans, no mining machines or locomotives, and simple pumps, there was need for little information other than about the mine atmosphere and the safety lamp.

With such a simplicity of operation, technical studies commenced, and as a knowledge of the theory of mining as then practiced was quite necessary, men were rightly required to show their efficiency in such studies before becoming mine foremen. The state examinations are still based on the conditions of that early time. We do not today educate men for their duties as foremen in a modern mine, so much as we school them so that they can pass the prescribed examinations; for these no longer determine whether a man is acquainted with the full range of the many duties that are likely to fall to him. When once the state examinations are passed we show little or no interest in his further development.

We have evolved a sort of classical education in mining. In earlier times men acquired Greek and Latin and did not hold it important to consider whether these studies really had any bearing on the problems actually to be solved in the workaday world. They continued to master them because such learning had attained predominance at a time when there was little else to study, and when the purposes of education were wholly different from those of more modern times.

The mining world branching right and left in its mechanical development, which is slowly but surely turning the mines into machine shops, now needs men of greater technical powers to handle its mine problems. It needs also many more than one man of technical knowledge in each mine to handle the multitude of new tools. It does not have any more a body of men who from childhood have been made acquainted with the implements by which the work is to be performed.

Many years back when the hand pick was not the symbol merely, but the mainstay of the industry, we had men who had learned from their fathers the fine art of handling that implement and who had been coached into the dangers of mining, the means of avoiding them and the tricks of operation. But the men of today have no such background of training in handling the modern tools of our constantly developing industry.

The operation of the new mechanisms may be more readily learned than the running of the more simple tools of the past, for the handling of a machine is often more simple than the deft manipulation of a less powerful and more primitive tool. But the art, hard or easy, must be learned, and there are few teachers on the mining force, whereas in our earlier operations there were as many teachers available as there were men employed, for every man knew mining, as then practiced, from "a" to "izzard."

We need, therefore, more and more mining schools in and about mine villages. In fact, at every mine the engineering staff should contain some man who by addresses or by training at the actual work, or both, should create increased efficiency in the handling of the mine mechanisms, the work to be supplemented by addresses given by experts at local centers. We shall only succeed when everybody knows how his work should be done.

The Chemistry and Constitution of Coal*

Much Has Been Done in the Determination of the Chemical Composition, Heating Value and Ash Fusibility of Various Coals. Recently the Microscope Has Been Brought Into Use and Has Proved a Great Aid in Determining Just What Coal Is Composed of and How It Is Built Up. Different Coal Beds Thus Appear to Be Composed of Totally Different Varieties of Plants

BY A. C. FIELDNER†
Pittsburgh, Pennsylvania

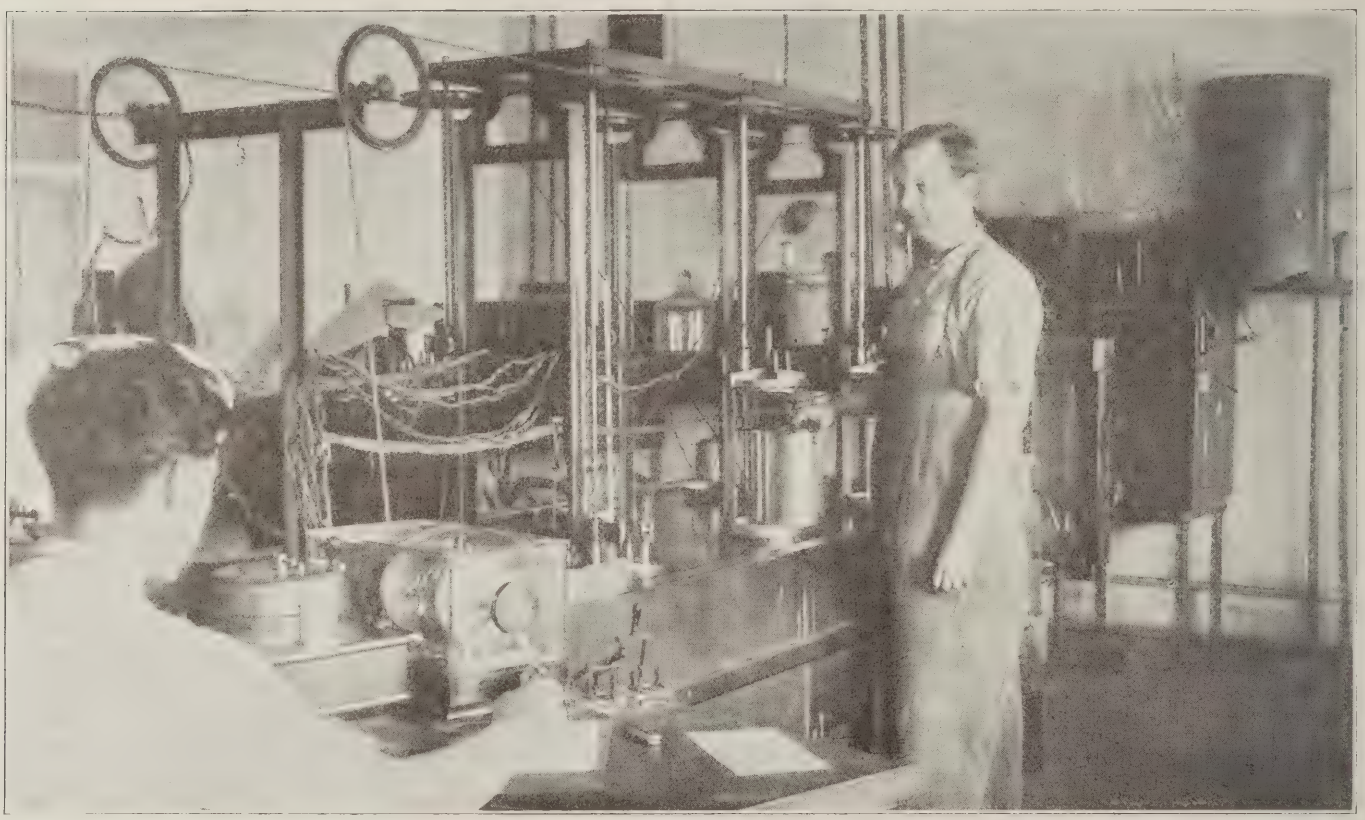

FIG. 1. BUREAU OF MINES' MULTIPLE CALORIMETER INSTALLATION

IN PRESENTING this paper on the chemistry and constitution of coal, I must explain that this all-inclusive title does not mean that it is either lengthy or exhaustive. I wish merely to give a brief review of some of the present-day aspects of the subject, with special reference to investigations that have been carried on in the Bureau of Mines Experiment Station.

Let us first consider the nature of coal. Geologists agree that coal has its origin in vegetable matter that was accumulated and buried in past geological ages. Several different theories have been advanced as to the exact manner of accumulation and the particular kinds of vegetation or vegetable products that were involved. At any rate, this accumulation became more or less altered and concentrated under swampy conditions and finally was buried under a load of sediment, to be subjected to a further change by heat and pressure.

In more or less intimate mixture with these organic remains was deposited silt, sand, clay and other earthy materials. Sometimes layers of sediment were laid down between the periods of plant growth, thus forming partings and veins of shale and slate. It is obvious, then, that the chemical constitution of coal must be extremely complex and must vary greatly from one bed to another. To determine all the real constituents in coal is beyond the power of a mere chemist. This will be appreciated later when the myriads of different substances that the microscope reveals are shown.

With our present-day knowledge we can only resolve this complex mass into its chemical elements, as is done in the ultimate analysis; or we may group the principal constituents into certain classes, as is done in the proximate analysis with which all are familiar.

The proximate analysis divides the coal into four classes of constituents: (1) Water or moisture; (2) mineral impurities that remain in a somewhat altered condition, as ash when the coal is burned; (3) volatile matter consisting of the gases and tars that are driven off on coking the coal; and (4) fixed carbon, which represents the carbonaceous residue or ash-free coke left behind after the gases are driven off.

The moisture and ash represent the incombustible or worthless part of the fuel, while the volatile matter and fixed carbon include the total combustible, which is de-

*Published by permission of the U. S. Bureau of Mines. Paper read at the Lexington meeting of the Kentucky Mining Institute, June 6, 1919.

†Supervising chemist, Pittsburgh Experimental Station, U. S. Bureau of Mines.

FIG. 2. TYPICAL FORMS OF ASH CONES AFTER HEATING IN NO. 3 MELTERS FURNACE

rived for the most part from the plant remains making up the coal substance.

In addition to the proximate analysis chemists have another method of attacking coal, and that is to resolve it into its chemical elements. All vegetable matter, and consequently coal, is composed principally of carbon, hydrogen and oxygen, with smaller quantities of sulphur and nitrogen. By suitable methods in the laboratory it is possible to determine with considerable accuracy the percentages of these elements.

Heating Values May Be Determined

From the ultimate analysis it is possible to calculate roughly the heating value of a coal. However, this method is no longer used, as an actual test in a calorimeter is more accurate and much simpler. The Bureau of Mines has a special multiple calorimeter installation in which six samples can be tested at one time, with an accuracy of 0.1 per cent (See Fig. 1). The results of such calorimeter tests are expressed in British thermal units. A British thermal unit is the quantity of heat required to raise the temperature of one pound of water one degree Fahrenheit.

In recent years, fuel engineers have demanded a test of the fusing temperature of the ash in order to get some idea of its clinkering tendencies. This test is made by molding some of the finely ground ash with the aid of an organic binder into small triangular pyramids about ¾-in. high and then heating them slowly in a furnace until the ash melts. The temperatures are read during this process and the fusion temperature is taken when the pyramid has melted down into a hemispherical lump, as shown in Fig. 2. The furnace used in the Bureau of Mines' laboratory is shown in Fig. 3. It is a slightly modified form of the No. 3 melters furnace of the American Gas Furnace Co. This furnace is operated with an excess of gas burning at the vent in order to maintain a reducing atmosphere in the combustion chamber. Under these conditions the iron in the ash is reduced to the ferrous state, which condition gives the lowest melting point and, therefore, the lowest temperature at which clinkering may result.

During the last two years the Bureau of Mines has conducted a survey of the fusibility of ash of various American coals. It was found that the average softening temperature of the ash of the different coal beds of the country ranges from 1900 to 3100 deg. F. Certain beds in West Virginia, such as the Island Creek, Coalburg and Winifrede of the Kanawha Group, and the

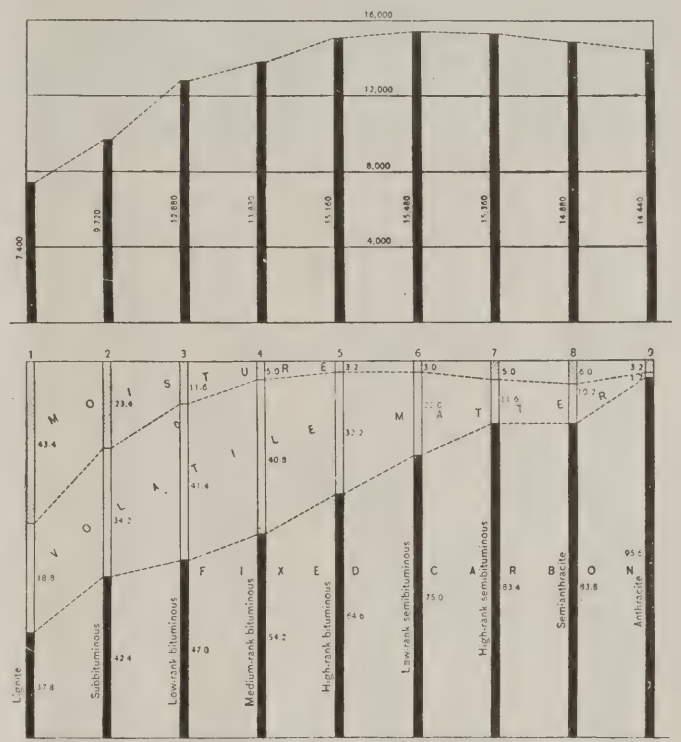

FIG. 1. CHEMICAL COMPOSITION AND HEATING VALUE OF THE SEVERAL RANKS OF COAL

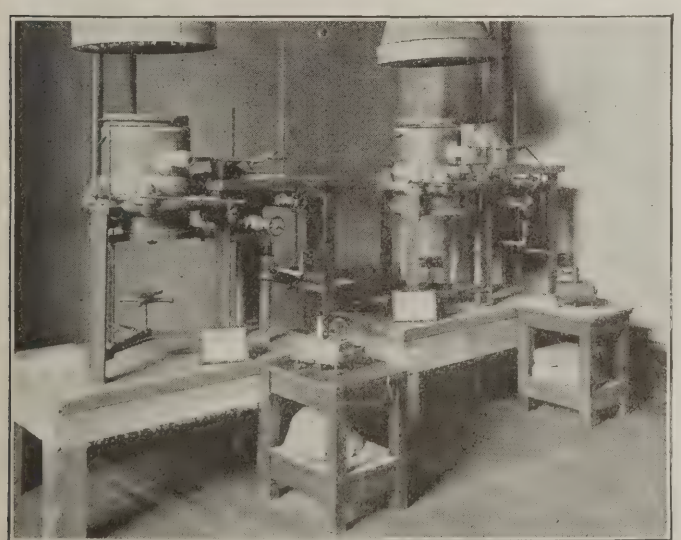

FIG. 3. FURNACES USED IN DETERMINING FUSIBILITY OF COAL ASH

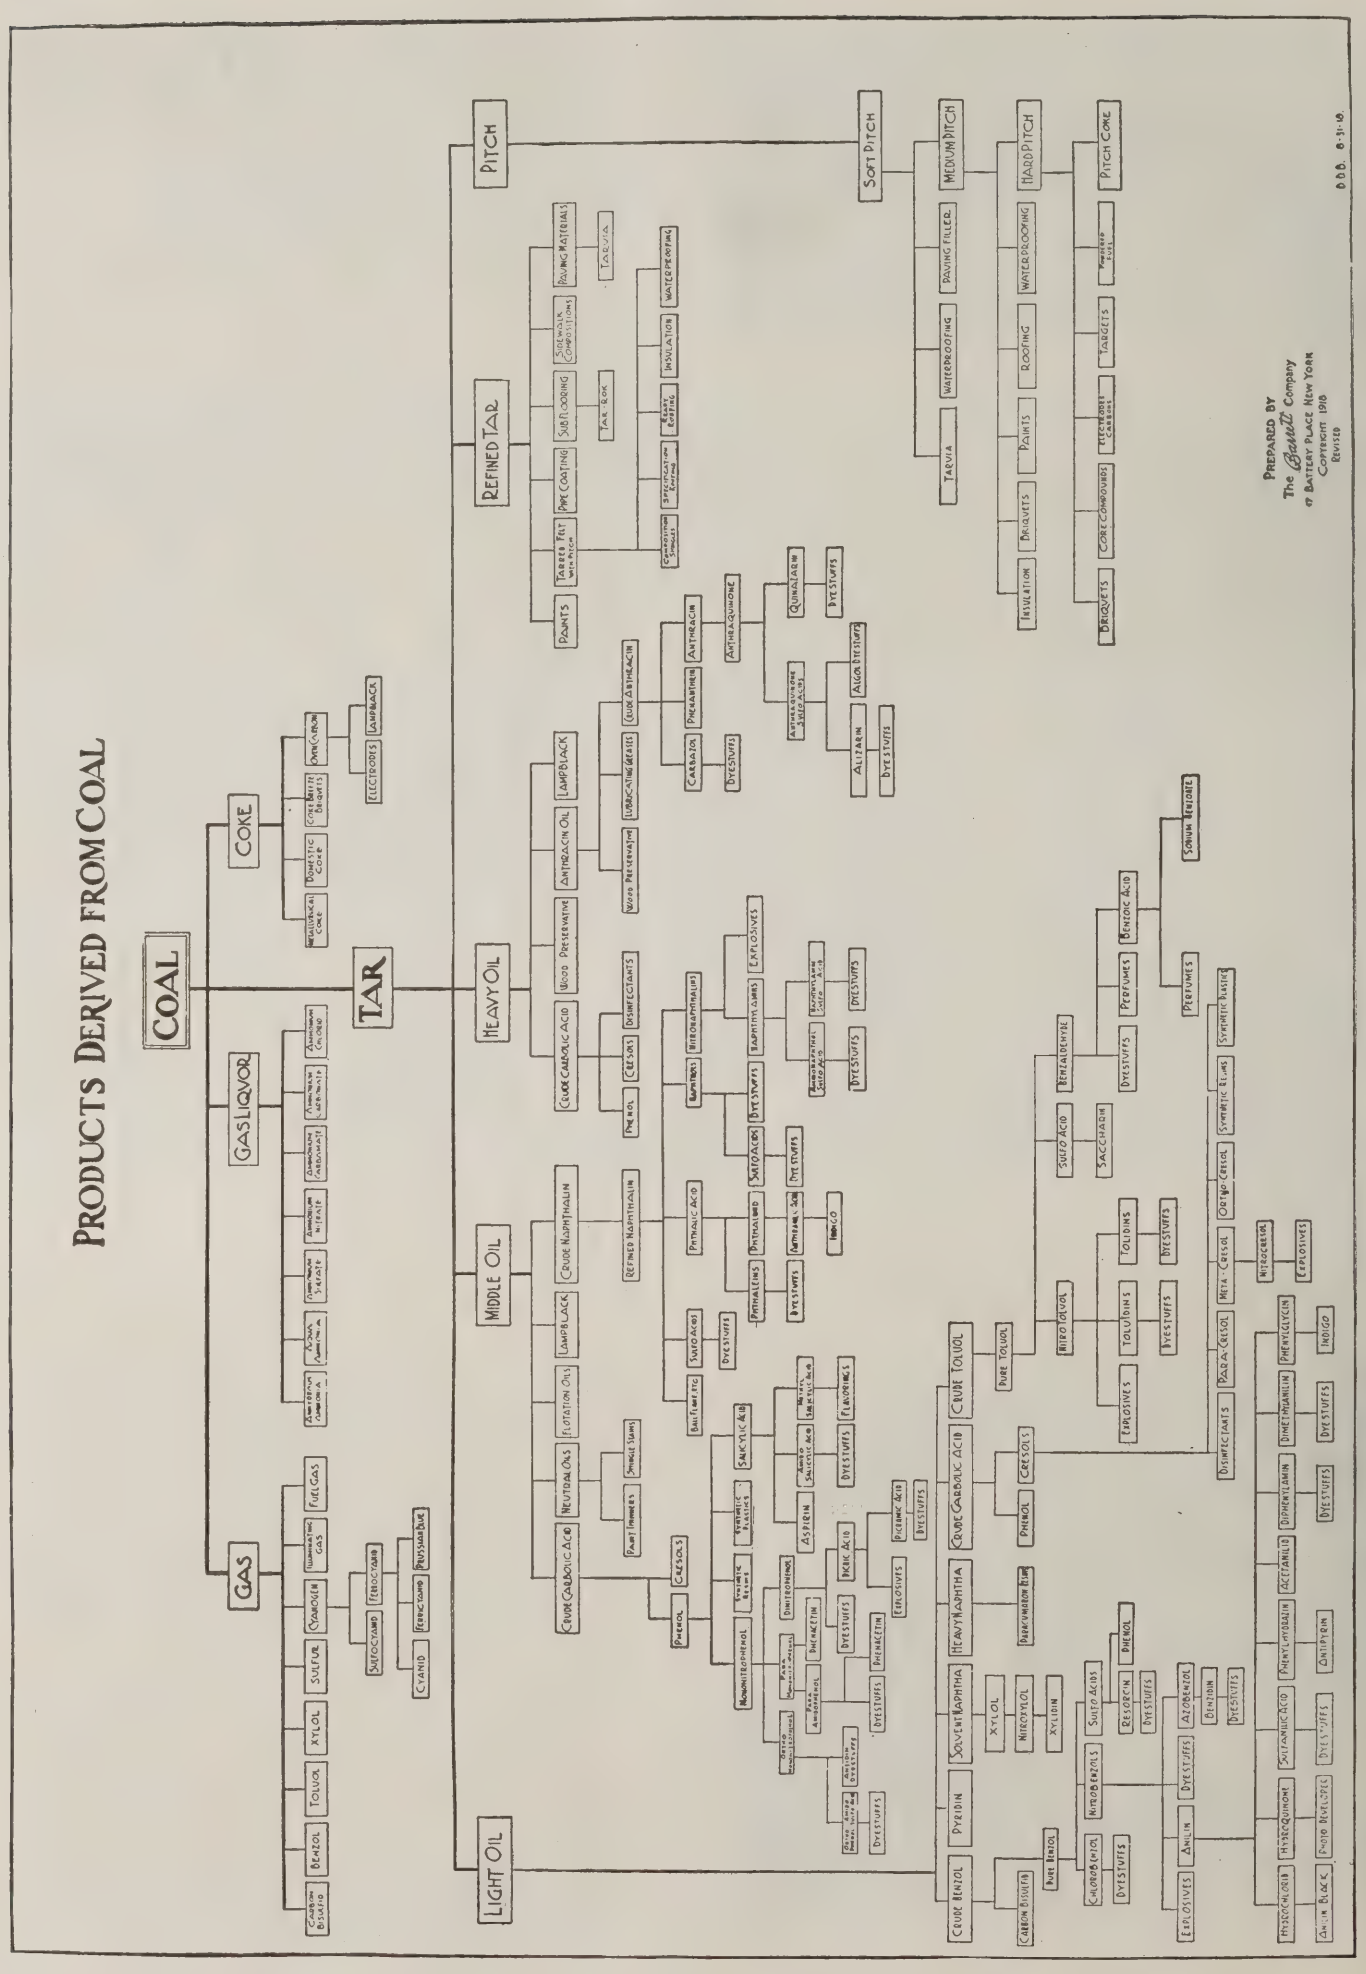
Beckley bed of the New River field, have a highly refractory ash with a softening temperature of 2800 to 3200 deg. F. On the other hand, the coal beds of the Monongahela, Conemaugh and Allegheny series, both in West Virginia and Pennsylvania, are characterized by ash that has medium to low fusibility—i.e., between 2000 and 2400 deg. F. But the most fusible ashes of all come from the coal beds of Illinois, Indiana, western Kentucky and Missouri. The following are the average softening temperatures for western Kentucky beds:

Bed No.	No. of Samples Averaged	Softening Temperature, Deg. F.
6	4	2130
9	75	2030
10	2	1990
11	39	2030
12	17	2150

These low softening temperatures are due to the high percentages of pyrite and lime compounds found in coals from the interior province.



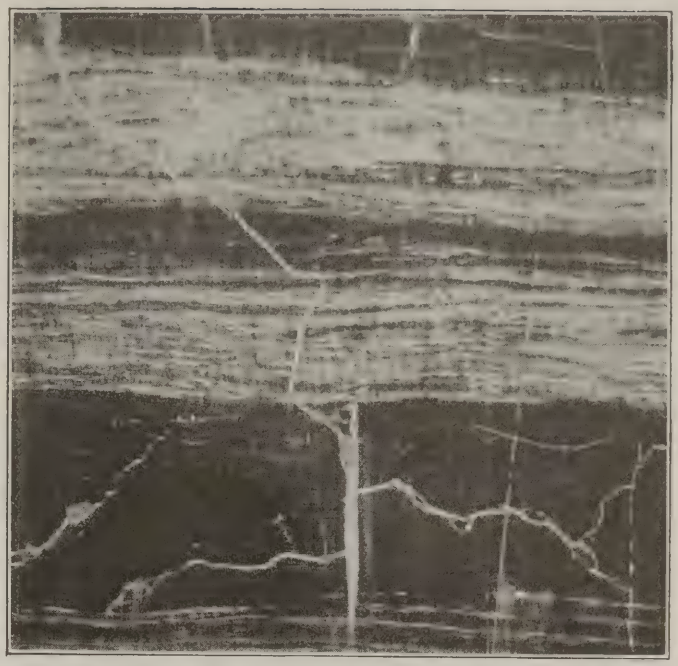


FIG. 5. CHART SHOWING THE LARGE NUMBER AND VARIETY OF PRODUCTS DERIVED FROM COAL

FIGS. 6 AND 7. A BLOCK OF ILLINOIS COAL FROM BED NO. 6, NATURAL SIZE, AND POLISHED SURFACE OF SAME BLOCK MAGNIFIED TEN DIAMETERS

The black bands represent "bright coal" or "anthraxylon"; the grayish bands represent layers of "dull coal"; the lenticular band near the bottom represents a cone of Lepidodendron

Eastern Kentucky coal has a more refractory ash as shown in the table on page 1155.

With the establishment of the United States fuel-testing plant at St. Louis, in 1904, the Federal Government began the analysis of coal from various parts of the country by uniform and standardized methods. This practice has been continued until the present time, first by the U. S. Geological Survey and since 1909 by the Bureau of Mines. Much of this work has been done in coöperation with the state geological surveys, which collected the samples and sent them to the Bureau of Mines laboratory for analysis. This plan has been mutually helpful to both the Federal and state authorities.

The results of all Bureau of Mines coal analyses are published[1] at regular intervals together with a full description of the mines and coal beds from which the samples are taken.

Classification of Coal by Ranks

On the basis of these comprehensive and uniformly made analyses, and also the physical characteristics, the U. S. Geological Survey[2] has worked out a scheme of classifying coal according to its rank, the word "rank" being used to designate those differences in coal that are due to the progressive change from lig-

nite to anthracite, a change marked by the loss of moisture, of oxygen, and of volatile matter. The change is generally accompanied by an increase of fixed carbon, of sulphur and probably of ash. When, however, one coal is distinguished from another by the amount of ash or sulphur it contains, this difference is said to be one of grade. Thus "a high-grade coal" means merely one that is relatively pure, whereas "a high-rank coal" means one that is high in the scale of coals—or, in other words, one that has suffered devolatilization and that now contains a smaller percentage of volatile matter, oxygen and moisture than it contained before the change occurred. This progressive change in volatile matter and also heating value with rank of coal is shown in the diagram (Fig. 4), taken from Camp-

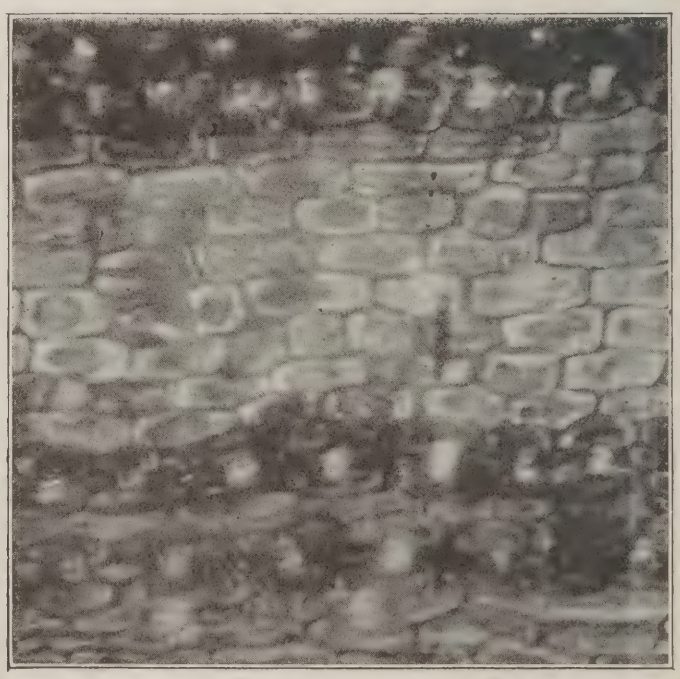

FIG. 14. ONE OF THE LEAF CUTICLES SEPARATED FROM THE COAL SHOWN IN FIG. 13, SEEN FLATWISE

bell's bulletin. It will be noticed that the fixed carbon gradually increases from 38 per cent. in lignite to 95.6 per cent. in anthracite. There is of course no definite boundary line between adjacent ranks; lignites shade into sub-bituminous coal and sub-bituminous into bituminous, so that one is often in doubt in which rank to place a given sample. Physical characteristics are also used to classify the rank of the coal as, for example, lignite is distinctly brown, markedly woody in appearance and slacks to a powder quickly on exposure to air, while sub-bituminous coal, the next higher rank, is black, less distinctly woody and does not slack so rapidly as lignite, although it is readily distinguished from bituminous coal because of this slacking property. Both lignite and sub-bituminous coals contain from 20 to 40 per cent. of moisture when freshly mined. This is readily given off on exposure to air and causes the slacking.

True bituminous coal contains from 3 to 16 per cent. of water, but is only slightly affected by exposure to weather. The fixed carbon varies from 40 to 70 per cent. This rank covers a wide variety of coals, as is well illustrated in the coals of Kentucky. In the western field is found typical low-rank bituminous coal with 8 to 12 per cent. moisture, 40 to 50 per cent. fixed carbon and 11,000 to 13,000 B.t.u. In eastern Kentucky there exist high-rank bituminous coals that are excellent for gas and coke production. These contain from 2 to 6 per cent. moisture, 50 to 60 per cent. fixed carbon and 13,500 to 14,500 B.t.u. There are also certain varieties of bituminous coal called cannel, splint and block coal.

Cannel coal is extremely rich in volatile matter and

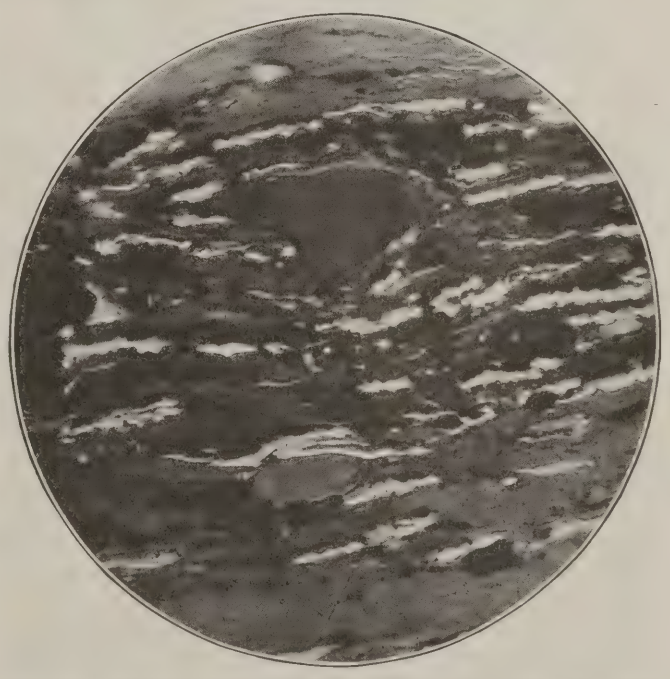

FIG. 16. HIGHLY MAGNIFIED CROSS-SECTION OF COAL FROM PITTSBURGH SEAM

Showing constituents of attritus in detail; spore exines in white; humic matter in gray; resinous particles homogeneous gray; and carbonaceous or mineral matter in black.

FIG. 17. SECTION OF ATTRITUS FROM PITTSBURGH BED, WHICH IS LARGELY COMPOSED OF SPORE MATTER

burns with a long, luminous flame. It is composed largely of spore exines and similar resinous or waxy products of plants, as can be seen from the photomicrographs. Block and splint are names indicating physical characteristics. Semi-bituminous coal and semi-anthracite represent intermediate ranks of coal between bituminous and anthracite. The classification is based almost wholly on the "fuel ratio," that is, the fixed carbon divided by the volatile matter. The limiting ratios for each rank are given in the following table:

Rank of Coal	Fuel Ratio = F.C. / V.M.
Bituminous	3 or less
Semi-bituminous	3 to 7
Semi-anthracite	6 to 10
Anthracite	10 to 60

The conventional chemical analysis and calorimeter tests afford much practical information that is useful in the utilization of coal, especially in evaluating it for fuel purposes. These methods, however, do not give any real information as to the constitution and origin of coal. This problem has engaged the attention of investigators for many years. Three different methods of attack have been followed: (1) Treatment of coal with solvents; (2) the destructive distillation of coal; (3) microscopical examination.

Chemists know that resins, waxes and similar substances will dissolve in certain solvents such as benzene, carbon disulphide, pyridine, ether, etc. Hence coal has been treated with many of these fluids in order to dissolve out its waxy and resinous portions and separate them from the purely cellulosic or plant fiber constituents. These researches showed definitely that coal contained resinous matter and also free hydrocarbons. Pictet, Ramseyer and Kaiser[3] extracted 5½ tons of Saar coal with boiling benzene for four days. In the extract they found and identified several pure hydrocarbons as, for example, C_7H_{10}, C_8H_{12} and $C_{30}H_{60}$ (Melene). The last-named compound was identified as the same as the melene obtainable from Galician petroleum.

The volatile-matter determination that is made in the proximate analysis of coal is a typical destructive distillation. The manufacture of illuminating gas and coke depends upon the same process. It is beyond the scope of this paper to describe the multitude of tars, oils, drugs, dyes and materials for explosives and fertilizers that are derived from the byproducts of the coke and gas industry. Fig. 5 gives the names of the more common coal products.

There is a wonderful field for future development in the production and utilization of these byproducts. We already know how to change the relative yield and quality of coke, gas and byproducts by changing the time and temperature of coking. And, as we learn more of the true constitution of various coal—that is, how the chemical elements are combined—we will be able to convert our bituminous coal into far more valuable products. Indeed the time is not far distant when smokeless coke and gas will be the only form in which coal will be burned in cities, and they will then be much more pleasant and cheaper places to live in.

Microscopical Examination

The various compounds obtained from coal on distillation, although not present as such in the coal itself, throw much light on the nature of the compounds from which they must have been derived, more especially when studied in connection with microscopical examinations of thin sections of coal. After all, the best way to find out how a thing is made is to take it apart and look at it. This is what Dr. Reinhardt Thiessen has been doing in the Bureau of Mines' research laboratory at Pittsburgh. Dr. Thiessen has developed a wonderful technique in cutting and grinding sections of coal to such a thinness that it is possible to examine them under the microscope at high magnifications with transmitted light, thus bringing out to plain view structure in coal that has never been suspected.

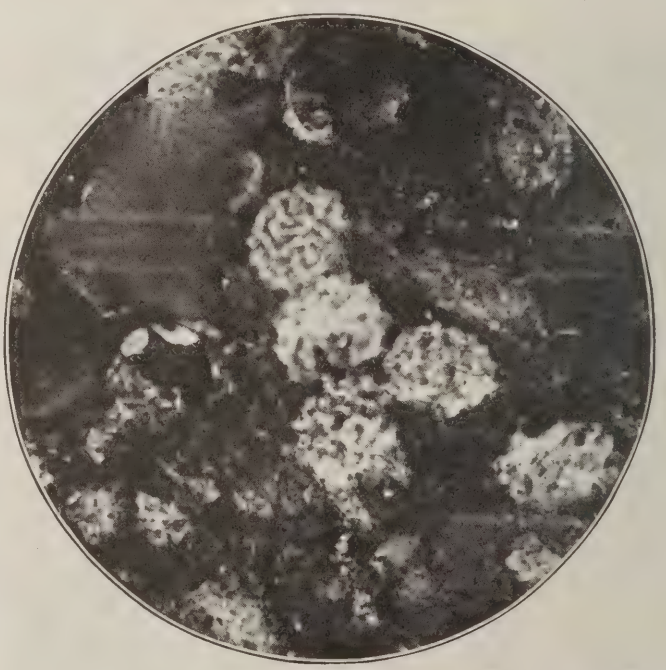

FIG. 18. HORIZONTAL SECTION OF PITTSBURGH BED COAL HIGHLY MAGNIFIED

Showing the convoluted spore that is characteristic of this coal bed and thus far found in no other bed

[3]Pictet, A., Ramseyer, L., and Kaiser, O., Comt. Rend. Acad. Sci., Vol. 163, pp. 358-361, Paris, 1916.

FIG. 19. MEGASPORE EXINES FOUND PREDOMINANTLY IN THE SHELBYVILLE, ILL., COAL AND SPARINGLY IN A FEW OTHER COALS

Dr. Thiessen has recently completed a comprehensive investigation of structure in bituminous coals that contains some wonderfully clear photomicrographs of high-rank bituminous coals. This represents a distinct advance in microscopic study, as these coals have hitherto resisted all efforts to cut or grind them into sufficiently thin sections to allow light to be transmitted through them.

A few typical sections which explain the composition of the bright and dull bands in coal are shown in the accompanying photographs. Fig. 6 is an ordinary photograph of a lump of Illinois coal that illustrates the laminated structure of most bituminous coals. Certain of the layers are of a glossy jet black appearance, others are dull grayish black. The former are usually called "bright" or "glossy" coal and the latter are called "dull coal" or "mat coal." Fig. 7 is a photograph of part of the surface of the block of coal shown in Fig. 6, magnified ten diameters. The "bright coal" is represented by the black bands and the "dull coal" by the lighter striated zones. Close examination of the "dull coal" at this low magnification shows that it in turn is sublaminated into thinner sheets of "bright coal" and "dull coal," the former being largely embedded in the "dull coal."

FIG. 20. GIANT MEGASPORE FOUND PREDOMINANTLY IN THE SHELBYVILLE, ILL., COALS AND SPARINGLY IN OTHER COALS

THE STRUCTURE OF BRIGHT COAL

Now let us examine a thin section of this bright coal under a microscope. Fig. 8 represents such a section magnified 200 diameters. Note the typical cross-grain structure of wood. A great number of bands of bright coal from many different beds were examined in the same way. All of them proved to be derived from woody plant tissue, either of stem, branch or root. The cell structure was well enough preserved so as to leave no doubt that the bright coal represents pieces of wood, large or small, turned into coal.

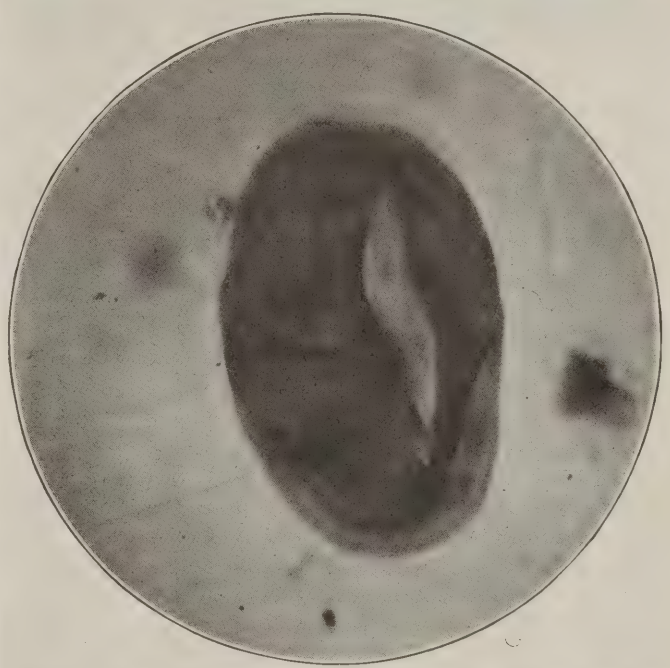

FIG. 21. ONE OF THE LARGER TYPES OF POLLEN GRAINS

Referring again to Fig. 6, it is seen even at low magnification that the dull coal has a sublimated structure of alternating light and dark bands, and on closer examination we find that the dark bands are "bright coal" embedded in a granular-appearing higher-colored material. And these "bright coal" bands in thin section and high magnification again prove to be woody tissue, that is, instead of being coalified trunks and limbs of trees, as were the large strips of bright coal that are visible with the unaided eye, they are small chips and twigs of wood embedded in a ground mass of vegetable débris, bits of macerated tissue, pollen grains, seed coats, resin particles, etc.

Fig. 9 is a photomicrograph of a section at right angles to the bedding plane of the "dull coal" zone. This is a thin section viewed by transmitted light and is magnified 200 diameters. The woody structure of the large fragment in the upper part of the picture

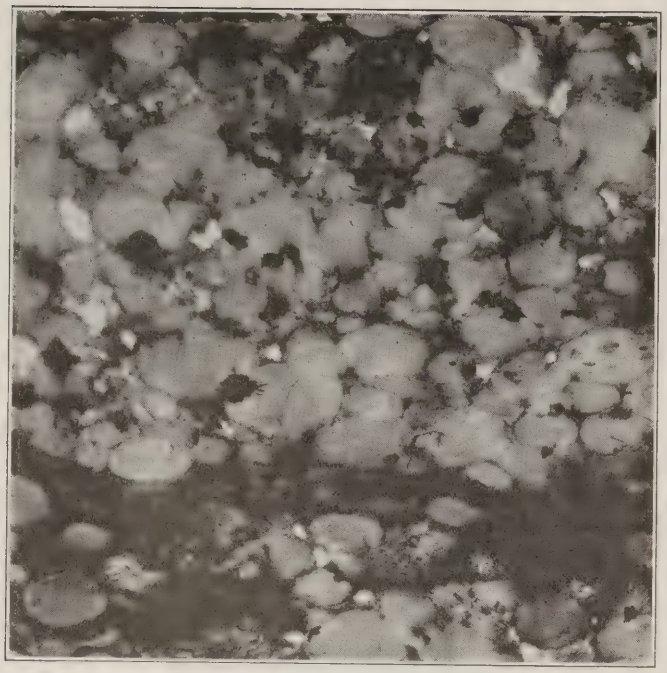

FIG. 22. CROSS-SECTION OF "DULL COAL" FROM THE VANDALIA MINE, TERRE HAUTE, IND., SHOWING A LARGER NUMBER OF RESINOUS PARTICLES

is plainly visible. In fact a large part (and in many bituminous coals the largest part) of the "dull coal" consists of small pieces of woody tissue pressed flat layer upon layer. The surfaces of these chips are readily seen even at low magnification by splitting the coal along the horizontal cleavage plane. Fig. 10 is a photograph of such a horizontal surface. The traces of woody chips are plainly visible.

Origin of the Small Anthraxylon or Woody Components

Dr. Thiessen has named the "bright coal" "anthraxylon," from the Greek *anthrax*, coal, and *xylon*, wood (coal from wood). He explains the presence of such formations in the coal by showing analogous conditions today in a peat swamp containing trees, as shown in Fig. 11. Fig. 12 is a lump of peat from this swamp. It shows a great many thin scaly chips which in the process of coal formation would probably become the thin layers of anthraxylon or "bright coal."

Let us now consider the thin vegetable tissues such as the outermost layers of leaves, green parts, young stems, etc. In many instances these skins, or cuticles, as the botanist calls them, are covered with waxy or resinous matter. They are therefore more resistant to decay and are found in the "dull coal" in the form of very thin layers, as in Fig. 13, which is a section at right angles to the layers. Figs. 14 and 15 also show cuticular tissue readily recognized by the trained botanist.

Between the layers of anthraxylon and cuticular tissues appears at high magnifications a heterogeneous mass of elongated light colored patches, irregular lumps of darker matter, and other débris, as shown in Fig. 16. This material is called attritus. It consists essentially of cellulosic degradation products or humic matter, spore-exines, resinous matter, cuticular matter, and some mineral matter.

Spore-exines are the outer shells or walls of spores of certain plants that contributed to all the coal beds. These spores are found to a greater or less extent in all coal. The attritus of Pittsburgh coal is particularly rich in spores, as shown in Fig. 17. The original spores were spherical in shape. In the coal there remains only the collapsed exine, or shell, which appears in the vertical section as a collapsed ring. In a horizontal section they appear as circular disks, as in Fig. 18. Note the brain-like convolutions of these spores, which is a striking characteristic of the spores of the Pittsburgh coal bed. This particular type of spore has never been found in any other bed.

Figs. 19 and 20 are spores from Shelbyville, Ill., coal and are probably characteristic of this bed, although not enough of the other Illinois coals have yet been examined to be certain that it is limited to this particular coal. Fig. 21 is a large pollen grain from the same coal. Fig. 22 is part of a thin cross-section of anthraxylon coal from the Vandalia Mine, Terre Haute, Ind., showing a large number of oval resinous particles.

The photomicrographs shown in this paper are only a few of many that have been made in the Bureau's laboratory. They represent a vast amount of patient, painstaking work, and have aided greatly in interpreting the results of chemical and geological investigations on the constitution of coal. Much remains to be done. Semi-bituminous coal such as Pocahontas and New River have thus far resisted every effort of the microscopist to produce sections thin enough to permit light to pass through them. Hence we have no direct information on the structure of these coals. The same, of course, applies to anthracite. However, what is impossible today is accomplished tomorrow, and we believe that the story of these coals will be read in the near future just as the structure of the bituminous coal has been revealed today.

Railroad Administrator Orders Change in Demurrage Rates

Of decided bearing to the coal trade is the change in demurrage rates ordered by the Railroad Administration. The statement issued by the Railroad Administration in this connection reads as follows:

Walker D. Hines, Director General of Railroads on June 21 signed Supplement No. 2 to General Order No. 7 referring to demurrage rules, regulations and charges, effective July 20, 1919. The charges at present are $3 per day for each of the first four days, after expiration of free time, $6 per day for each of the next three days, and $10 per day for each succeeding day.

They will be reduced to $2 per day for each of the first four days, after the expiration of the free time, and $5 per day for each day thereafter. The Supplement also provides that the average agreement which at present applies only to cars held for unloading will also be applied to cars held for loading, but the loading and unloading agreement will be separate.

Representatives of the shippers and of the American Railway Association recommended reductions. Mr. Hines pointed out that demurrage charges are not imposed for the purpose of securing revenue but to assist in the punctual unloading and loading of equipment and also that in view of the diminished purchasing power of the dollar and the increasing demand for equipment it was doubtful whether the prompt unloading and loading of equipment could be secured by means of these reduced charges. He referred to the heavy movement of traffic expected within the next few months and announced that if the results were not successful he would feel compelled to increase the demurrage charges.

Some Common Violations of the Mining Laws*

The Chief of the Department of Mines of West Virginia Unburdens Himself of a Few Opinions Regarding Mining Conditions and Safety in Mining, and Enumerates Some of the Reasons for Accidents

RECKLESSNESS and ignorance, according to W. J. Heatherman, who heads the mine inspectors' department of the State of West Virginia, are the chief obstacles to mine safety. The failure to set proper timbers, shooting from the solid, riding on trips, and the lack of adequate facilities for entering and leaving the workings are some more of the causes of mine accidents. Many mine officials, believes Mr. Heatherman, woefully lack a proper conception of their own responsibility and do not attempt to enforce precautionary measures.

TO MAKE the coal mines of West Virginia a safer place in which to work is the main object of the Department of Mines. Recklessness and ignorance are the foes with which we have to contend. They are at the root of every disaster. The mining laws of the state are the safeguards thrown around the men who mine coal. Their enforcement is vested in an inspection force which is continually making inspections of mines, removing hazards and curing defects that appear dangerous to life and limb.

The mine inspector, in reality, is a traffic officer, like the one who stands at the intersection of a busy street and guides the pedestrian on a course of safety. Frequently some reckless individual ignores the warning of the traffic officer and courts disaster by a rash act. The same is true of the warnings of the mine inspector. Familiarity breeds contempt, it is said, and this is most certainly true of the attitude of many miners in the observance of most of the ordinary rules of safety.

The most common violations of the mining laws are the failure of men to set timbers for their own protection, the shooting of coal from the solid, the riding of mine trips and the failure to provide proper methods of ingress and egress to the mines.

The records of the Department of Mines show that 50 per cent. of the accidents in the mines of the state are caused by falls of roof. The majority of these occur between the timber and the face of the coal where the miner has failed to post. It is indeed a common sight to visit a working place and find the miner working from 6 to 16 ft. ahead of the last timbers, while the roof over him is in a dangerous condition.

In reply to an inquiry as to why the miner does not set another prop here and there, you will most frequently receive the same answer—"I will, as soon as I finish loading this car"; or such a query will be met by the assertion that "That's good roof." Pursuing such an inquiry will develop that the miner is without an ax, or if he has one he uses it as though he had never seen that sort of instrument before. The law should require that every miner possess an ax, a good hammer, a slate bar and at least two good wedges, and that he serve as an apprentice or "backhand" for at least six months before he is allowed to work in a place by himself.

Can you imagine a railroad trusting one of its limited trains in the hands of a man who never saw a railroad before? As a matter of fact it is easier to learn to start and stop an engine than it is to be a good judge of roof conditions.

There is not another trade or profession under the sun that does not require an apprenticeship of from one to four years, and often longer. The inexperienced and unskilled miner not only faces unknown dangers, but he endangers the lives of all his fellow workers.

It is essential that every mine should have a well-defined rule as to the location of posts and when the timber should be set. Mine foremen should require strict and uniform observance of this rule.

Frequently, however, mine foremen may be found who do not realize the gravity of their duties. They are content to go from place to place, begging a cigaret here and some carbide there, with an occasional inquiry to the miner as to "When are you going to set that post I told you about yesterday?"

In my opinion, the mine foreman is the most important element in the mining organization. And yet there are some mine foremen who really do not know the way through their own mines. The mine foreman ought to be selected carefully: he is the general in charge; upon him depends the success of the business venture as well as the lives of the men who work for him. He ought to be a clear-headed, intelligent, industrious man possessed of executive ability.

The second offender in the percentage column is mine cars and motors. Next to falls of roof the riding of mine cars and motors by employees in the mines leads to the greatest number of casualties. To lessen the number of accidents from this source no man should be permitted to ride any other than a regularly conducted man-trip. Brakemen should be required to ride on the inside of the empty cars and on the rear of all loaded trips. Couplings should be made only while the trips are standing. Ample clearance should be maintained on the brake side of the car at least, so that a man may pass a moving trip on curves without danger of being caught or rolled against the rib. Another invitation to disaster, which ought to be sufficient cause for suspension, is the practice of standing in the middle of the track and boarding an oncoming trip or train.

The average motorman and brakeman are young fellows, who are often placed in charge of trains without any knowledge of the machinery they handle. They might be called starters and stoppers, or wreckers.

I feel that each motorman should be required to pass

*Paper presented before the West Virginia Coal Mining Institute, Charleston, W. Va., June 4, 1919.

an examination to show that he understands the use and care of brakes, the necessity of good contact, why oil cups are provided, and that he can make just as much speed with his pole trailing as he can "back-poling." I know from experience what means it is necessary to resort to at times (especially on the Monday following the old payday) in order to get all the motors out of the barn. But I believe that such necessity can be overcome to a certain extent by having an occasional meeting with the train crews. You might call it the Knockers' Club, but if you invite them to your office every few weeks and lay before them statistics concerning the number of men they have killed and crippled, the number of cars they have sent to the shop, and what the cost of each locomotive has been, and do it in the proper manner, I believe you will find an appreciative audience and a much-improved set of trainmen. After all, they are only human and a youthful lot, and many of them have not had the advantages of education. These frequent conferences should be advantageous in many ways. No one should be more competent to tell you where to find a piece of bad track or a dangerous roof condition than your train crew. Have your assistant mine foreman present at these meetings and you will be able to discuss and adjust your difficulties, so that when a motor or piece of track is marked for repairs it will be repaired.

The average foreman closes his eyes to boys and men riding huddled between loaded coal cars, and will tell you if you reprove him that he is perfectly willing to go to the next place. Therein lies one great reason for the lack of discipline around the mines today. I would like to suggest that the operators assist in organizing a mine foreman's institute, to be held as often as is necessary to allow each mine foreman in the state to attend and hear qualified men lecture on the duties of a foreman. This would tend to arouse a spirit to overcome the constant and flagrant violations not only of the mining laws, but all laws having for their purpose the elevation of man. The foreman's institute should teach that the same discipline in enforcing the laws should be in effect in every mine in the state.

Solid shooting is one of the most dangerous practices allowed in our mines today. The only remedy I can suggest would be to have the proper section of the mining laws revised so as to require all coal to be undercut, and where it is hand-mined no cuts should be shot down until some official has made an inspection.

It may be contended that solid shooting "bats out of turn," for the reason that so many accidents are traceable to it. I think many slate falls are premature for the reason that the strata are fractured by overcharged holes, and there is little doubt that several of our largest explosions have been the result of blowout shots or were caused by shooting from the solid.

Where solid shooting is permitted the use of black powder should be avoided. In fact I would like to see written on the statute books a law forbidding the use of black powder and fuse inside the mines of West Virginia. Where men are permitted to use permissible explosives and fuse they will invariably resort to the use of short fuse. There are only two ways to eliminate the hazard. One is by legislation, as I have suggested; the other is for the company to refuse to handle fuse. If the miner were made to realize the amount of money he would save by properly placing and tamping his holes, as well as the danger in which he places the lives of his fellow workmen, I really believe he would readily accept the electric firing and submit willingly to the adoption of permissible explosives.

I regret to say that many of our mines pay little attention to their traveling ways. In fact there are dozens of operations at the present time where one must be both an expert swimmer and climber in order to reach the outside, if he leaves the main haulage road. In many instances I have found the main hauls so badly gobbed that one either had to flag the trip or outrun it if he did not care to be crippled.

I venture the assertion that half the foremen in the state do not travel their returns more frequently than every six months. Every foreman should keep such returns in shape for men to traverse at all times, and should insist upon manholes as required by law.

In conclusion, permit me to make the suggestion that foremen pay occasional visits to adjoining mines where the accident rate is lower, or go from county to county to make inspections and see what methods are being employed in other mines to make them safer for life.

THREE VIEWS OF THE TIPPLE OF THE VALIER COAL CO., VALIER, ILLINOIS

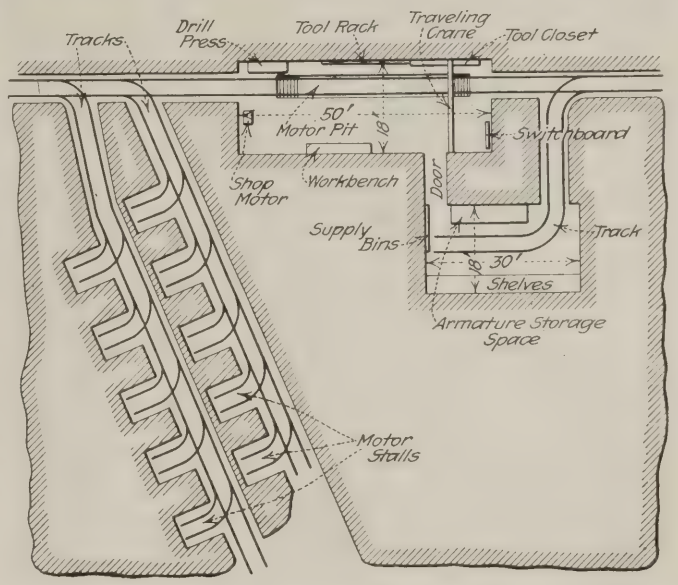
From left to right the views are of the main shaft under construction, the air shaft where men and material are handled, and a second view of the main shaft under construction. The mine will be one of the largest and most modernly equipped in the state. Its capacity will be 7000 tons per eight-hour day. It is electrically equipped throughout. The haulage is by means of storage-battery locomotives. Both shafts are arranged for hoisting, the air shaft being provided in the tipple with a rotary dump, which handles a 4-ton mine car. The main shaft is equipped with a 12-ton double skip hoist, with a modern rotary dump at the bottom. Edison storage-battery cap lamps and other safety appliances will be used.

Underground Motor Repair Shop

By Ralph W. Mayer
California, Pennsylvania

A LARGE company that has immense coal mines does its motor repair work underground. The shop used for this purpose is situated over four miles from the tipple. It is 50 x 18 ft. in size. The roof is shot down to give it a height of 15 ft. and the sides and ends of the room are lined with heavy stone walls. The roof is supported by steel rails, over which is placed sheet steel, the space between the roof and the sheets being filled with concrete.

A track runs through the shop. Underneath the track has been taken up and a motor pit having a depth of 6 ft. has been built. Both ends of the pit are provided with steps made of concrete. The sides and bottom of the pit are constructed of the same material as is also the floor of the shop. Eighteen inches from the pit bottom the side walls have an offset of 4 in. Short lengths of plank can be placed upon these offsets, forming a platform to work upon. The side walls of the shop, near the roof, have an offset on which a steel rail is fastened. A Cleveland electric crane travels upon these rails and will reach any part of the shop floor. It is operated by a small motor. The side walls only partially support the roof, as the steel rail roof beams are set into deep hitches at the side.



One corner of the shop contains a drill press, an emery wheel and other small machinery. The power for driving these tools is furnished by an electric motor, which is placed overhead at the end of the shop, out of the way. The pit is located at one side of the shop. Racks along the wall on this side hold the wrenches and other necessary tools. A closet on the same side near the end of the shop, provided with doors and locks, furnishes a storage place for the smaller and more valuable tools. The switchboard is placed in the opposite corner. The work bench, equipped with a vise and other appliances, is placed at the side of the room opposite the pit. The entrances to the shop are closed with sliding steel doors, hung on rollers. These are of course provided with locks. The motors are re-wheeled in this shop, and other necessary repair work is also done here.

A storage room adjoins the shop, being separated from it by a pillar of solid coal. A passage way through this pillar, which connects the two rooms, is also closed by a steel door. This storeroom is 30 ft. by 18 ft., but only the height of the coal, or about 7 ft. It has a solid rock roof, while the sides are lined with brick walls. A track also traverses this room, which is also closed by a steel door.

One side of the room is provided with racks for the storage of armatures, field coils, etc. Electric heaters placed underneath this rack keep these spares absolutely dry. Both rooms are entirely free from water. Shelving along the opposite side of the storeroom is filled with spare parts for motors, pumps and other machines. The framework supporting the shelves is made from 1½-in. pipe. Clamped fast to the pipe are pieces of L-shaped iron which support the steel sheets used for the bottom of the shelves. The L-shaped irons are also used to separate the contents of the different compartments. Along the ends of the room also are supply bins. The passageway between the two rooms contains a desk where the records of the repair shop and of the storage are kept. Work is done here on all the haulage, pump and fan motors, as well as the repairs on the pumps. All spare parts have to be kept here, as well as supplies for the mechanics, such as tape, sandpaper, lamp globes, etc.

The locomotive stalls are close to the repair shop. All these machines have numbers painted on their sides with white paint, and each stall has a corresponding number painted at its entrance with an arrow pointing into the stall. At the end of every shift each motor must be placed in the stall having the same number as the motor.

The company has 44 haulage motors in this one mine, all of which are placed in their stalls at the end of the shift. They are then overhauled by the mechanics of the repair shop. Two shifts of mechanics are employed for this service. A split point throw switch is placed at the entrance to each stall. Pillars of

LAYOUT OF AN UNDERGROUND REPAIR SHOP

coal separate the stalls, which are long enough and wide enough so that there will be several feet of clear space around the motor when it is in place. The repair shop also cares for the repair work on the 35 pumps employed in the mine.

These are usually repaired where they are installed in some new location, the mechanic taking the packing or repair parts to the pump. Any haulage motor breaking down during the day is brought to the shop and immediately repaired if the injury is not too severe. Any of the stationary motors giving trouble are reported to the shop, and a mechanic sent at once to locate and repair the difficulty.

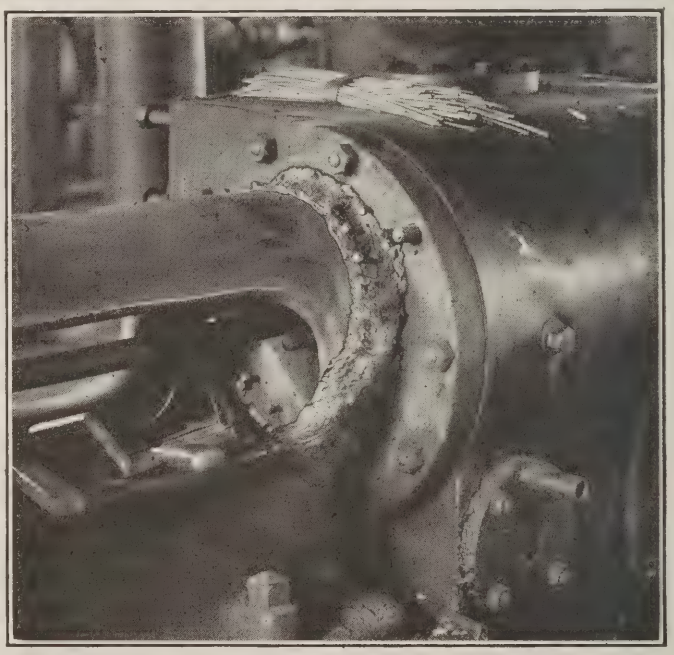
Having the repair shop and mechanics right at the center of gravity of the haulage system, so to speak, saves time. Placing the motors in their stalls at the end of the shift and having them inspected and if necessary overhauled by mechanics forestalls breakdowns, and keeps the machines in good shape thus reducing repair expenses. This constant care also lengthens the life of the locomotives.

The British Government is spending $750,000 in a large experimental plant in which near-coke will be manufactured by subjecting coal to low-temperature distillation.

The Plastic-Arc System of Welding*

ELECTRIC welding fooled the officers and men of the interned German ships. They had smashed the cylinders and other parts of their engines until they believed they were beyond repair. However, the engines were repaired in place, and the vessels did good work in the transportation of American troops. Electric welding has its application in coal mining, but for arc-welding purposes a suitable welding metal is as necessary as a proper electrical outfit.

By J. O. Smith
New York City



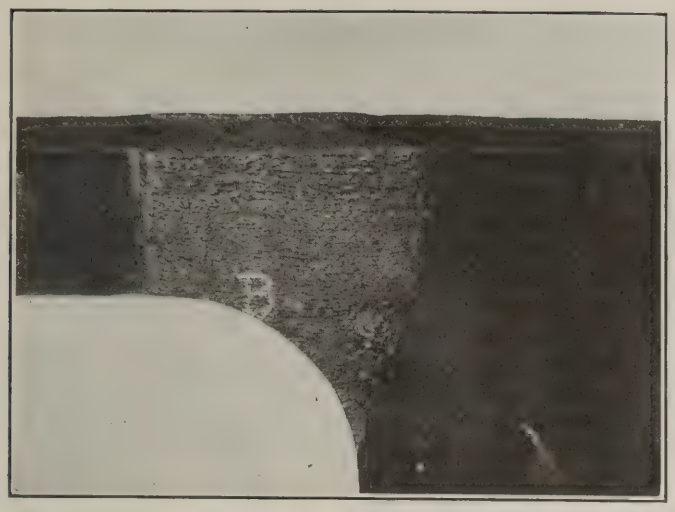
ELECTRICITY as a means for the joining of metals, in repairing cracks or breaks, salvaging defective castings and for metal-cutting purposes, all included under the general head of electric welding, although comparatively simple in theory has been slower in development in the coal-mining field than in any other service in which it has been applied. This slow growth probably arises from two causes—the scarcity of skilled operators and a dearth of reliable apparatus suitable for performing the actual operation.

During the last two years, however, arc welding has made great strides. Undoubtedly one of the means whereby it has attained greater prominence, and the confidence of the engineering world in general, was the successful welding of the damaged parts of the interned German ships at the outbreak of the war in the spring of 1917. The work that was done on the damaged engines of these ships demonstrated to the engineering world in general that electric welding could be depended upon to make permanent repairs, no matter how large or bulky the part to be welded, or what was the character of the metal.

There are four general fundamental types of arc-welding outfits in general use—constant potential, with fixed resistances; variable potential, rising and falling inversely as the current rises and falls; constant current (all of these employ direct current) and the alternating-current type, with reactive control. The constant potential system is the oldest of those employing direct current. It operates on a generator potential of between 35 and 40 volts and uses 18 to 22 volts at the arc for actual welding.

A distinct advantage of low voltage at the arc is that it renders it impossible for the operator to draw out a long arc between the electrode and the work. The deposition of clean, sound metal resulting in a good weld is largely a question of the operator's skill in maintaining a short and even arc, which eliminates oxidization of the molten metal by the air and insures the metal being deposited in the correct place. The voltage across the arc increases as the arc lengthens, and if the voltage is too low to maintain anything but a correct length of arc it follows that the operator has a surer indication (when his arc begins to weaken) that he must shorten the distance between his electrode and the work. With a low-voltage supply the external appearance of a weld is a certain guide to its value, and it can be safely reckoned to be free internally from any dangerous slag or oxide inclusions.

In the variable potential system, the current and voltage balance one another to a certain extent, the current varying principally with the length of the arc and maintaining its greatest stability when the arc is of considerable length. The long arc, however, is not generally advocated, because of diffusion at the surface of the original metal, and because of the tendency of the original metal to become porous and also to oxidize. The constant-current system is used primarily for single-arc outfits, although arcs in series can be used.



WELDING REPAIR ON STEAM ENGINE

The steam engine at the Public Service plant in Jersey City, N. J., broke practically in two. It was welded and put back in service by the plastic-arc system

Because of the alternations of the current, it is practically impossible to draw a long arc in the alternating-current system, and further, because such an arc is much more sensitive to variations in its length than in direct-current systems a higher voltage is necessary to steady it. Coated electrodes are used with the alternating system.

In the Wilson plastic-arc system, which comes, of course, in the constant potential class, the power lost in the line and in the automatic current regulation is of

*Abstract of a paper presented before the first meeting of the Coal Mining Electricians and Mechanics Institute, Charleston, W. Va., May 30, 1919.

COMPLETED WELDING REPAIR ON A BRAKE

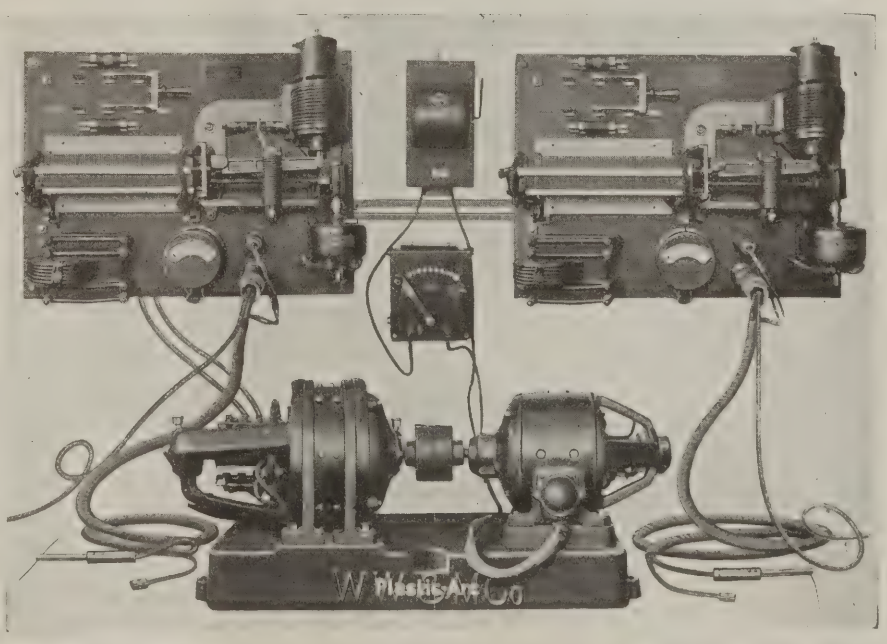
low value compared to the energy actually required for welding. There is consequently a great saving over systems employing higher voltage. The low voltage used (18 to 22 volts at the arc) also insures better penetration of the original metal by the concentrated arc than is true when a longer, diffused arc of higher voltage is employed.

The comprehensive repairs necessary in the case of the damaged engines and other parts of the interned German ships definitely determined that any welding system, to be considered available for such heavy work in cast iron or cast steel, must deliver and maintain a critical degree of heat at the weld, in order to insure proper fusing of the original and the added metal.

This condition is successfully accomplished by means of a standard flat compound 35-volt generator feeding a special constant-current controller. The carbon pile and a solenoid that operate the arc are in series with it, so that the current through the arc is controlled by the automatic variation of the resistance of the carbon pile in response to the pull of the solenoid. The pull of the solenoid is balanced in turn by a spring acting through a leverage system, and the current adjustment is made by changing the leverage. The pilot motor, which is controlled by a switch at the welding-tool handle, regulates the leverage so that the operator can change the current at the arc, if necessary, without leaving his work or extinguishing the arc. This is a desirable feature in ship or general welding repair work.

The subject of the repair of the interned German ships brings up a matter that assumes greater and greater proportions the further consideration of it goes. It must be remembered, first of all, that some of the largest and fastest ocean steamships afloat were included among those deliberately damaged by their crews to prevent their use by the United States as transports, and that these same vessels eventually carried one-quarter of the total American expeditionary force to the battle fields of France, just in time, as we all know, to be where they were badly needed to stop the onrushing Hun. Had the repair of these ships not been effected as promptly as it was, there is no telling how much bearing the belated arrival of our troops on the firing line might have had on the final result. For all we know, the war might still be going on.

Part of the annual report for 1918 of Secretary of the Navy Daniels, which has a distinct bearing on this phase of the matter, is as follows:



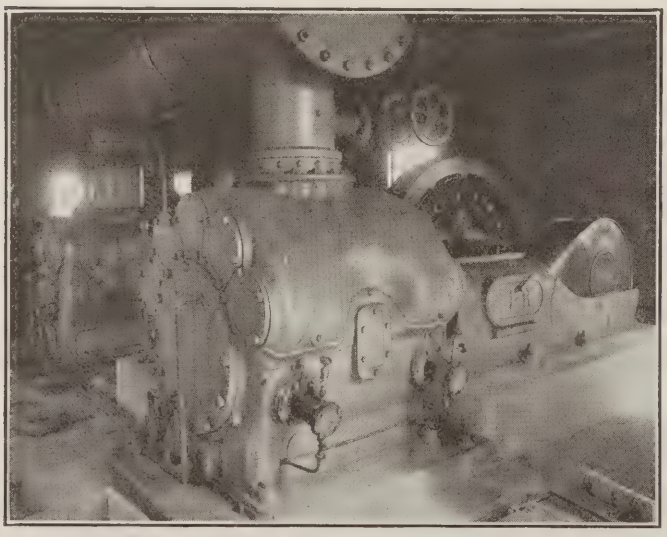
When war was declared with Germany all the German ships lying in our ports, many of them of the highest class of transatlantic passenger steamers, were immediately taken over by our Government. Upon examination it was found that the machinery of all of them had been deliberately damaged by their crews, in many cases seriously, and the character of the injury was such as to denote that the work had been carried out under a central direction and that it had been well planned.

When taken over, these ships, to the number of 103, were put under control of the Shipping Board, which later transferred 34 of them to the Navy for use as troop and freight transports, and subsequently added 20 more to be repaired and returned to the board.

The principal damage was the breaking of cast-iron parts of the main engines, chiefly the cylinders, though in one case rods, connecting-rods and boiler stays were sawed half in two, and in others the boilers were ruined by dry-firing and had to be renewed. There was, in addition, much vandalism of a minor character, but the remedying of this was insignificant in comparison with the gigantic task of repairing the cylinders, some of which were more than 9 ft. in diameter.

It was speedily recognized that the large passenger ships thus taken over would have to be our chief reliance in transporting troops to France, and their quick repair became a matter of great national interest. After a survey by representatives of the Shipping Board, which at the time had custody of them, it was decided to make new cylinders. This decision was in accord with usual practice and also with the rules of the marine underwriters, and but for the number of ships and the large number of cylinders involved would probably have been followed. But the time required was prohibitive, and while the subject was under discussion a few of the ships were transferred to the Navy and sent to the New York Navy Yard for repairs.

As the Navy was not bound either by previous practice or the rules of marine insurance societies, the engineer officer of the yard, Capt. E. P. Jessop, U. S. N., after conference with an electric welding company recommended that the broken cylinders be repaired by welding, and in



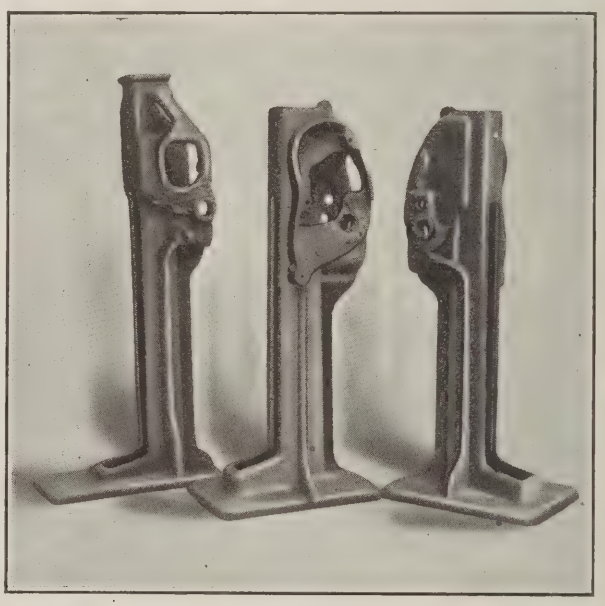
NECESSARY ELECTRICAL OUTFIT FOR WELDING BY PLASTIC-ARC PROCESS

this he was heartily supported by Rear Admiral Burd, the industrial manager of the yard. The matter was referred to the Bureau of Steam Engineering, and Capt. O. W. Koester, assistant to the bureau, was directed to make a thorough examination of all conditions on the ex-German ships. As a result of his investigation, orders were issued to make all repairs where possible by electric welding, and to resort to mechanical patching only where welding was impracticable, and the department supervision of the work was thereafter under the personal direction of Captain Koester.

This decision, so far-reaching in its application and so fraught with danger to the professional reputation of the officers concerned, was made in the face of opposition by engine builders and by marine insurance companies, but with such confidence in the ultimate result as left no room for doubt of its success. Electric welding was well known but its application on such an extensive scale was unprecedented; by its use these damaged cylinders could be saved, the work could be done without removing the cylinders, and all the vessels could be made ready for service probably a year before they could have been if the cylinders were renewed.

Upon completion of repairs, which were carried out uninterruptedly for 24 hours a day, each vessel was sent to sea for a test under full-power conditions for 48 hours, the purpose being to ascertain whether the work of repair had been well done and to determine whether the ships were in condition to be intrusted with the transportation of troops. So well and so successfully were the repairs accomplished that there was not a single instance of a defective weld, nor has one developed during the months of arduous service on which these ships have been engaged.

I have entered upon so full a statement of this case because I think it stands out as one of the greatest engineering achievements of the period. The perpetrators of the sabotage were confident that they had damaged the machinery of these ships beyond repair, which fact is evidenced by a memorandum found on board one of them, in which each case was carefully noted, followed by the significant remark, "Cannot be repaired"; and the speedy rehabilitation of these vessels in the face of such German confidence is a splendid triumph of American ingenuity and an evidence of American engineering accomplishment that is deserving of the highest commendation. The restoration of these magnificent ships to service reflects the greatest credit upon the naval officers concerned and upon the officers and employees of the welding and engineering companies who carried out the work. It is an illustration of the part played in winning the war by men who handled an electric torch or who fashioned and secured mechanical patches to these damaged cylinders. Without these ships we could not have transported our troops to France as rapidly as was done, and the men who made this possible performed a service of as high an order as have the brave boys who were thus enabled to take their place on the fighting line.



CAST-IRON ELECTRICALLY DRIVEN AIR COMPRESSOR REPAIR

This compressor, at the plant of the New Jersey Zinc Co., at Ogdensburg, N. J., was cracked in several places, due to a fire at the plant. It was repaired in place by the plastic-arc welding method

As a sidelight on this work it has been made the subject of careful estimate and determination that the repair of these ships resulted in a saving of 12 months in time, enabled us to transport at least 500,000 troops to France, and effected an economy which is conservatively estimated at upward of $20,000,000.

It will be recalled that for a few days previous to the declaration of war, the newspapers of the country had printed articles about mysterious doings and noises aboard the German ships then interned in our ports. These articles told of sounds of heavy pounding being heard throughout the days and nights on board these ships, and of splashes during the nights as though heavy pieces or parts of machinery were being thrown overboard.

BROKEN JACK STANDARDS RECLAIMED FROM SCRAP PILE BY WELDING

It was not known then, of course, to what extent we had to deal with *Kultur* and its refinements, and we did not realize the lengths of infamy and destruction the Hun would resort to; but after the vessels were taken over, it was discovered that the pounding was the result of driving tapering wedges into holes previously drilled into cylinders and other parts of the interned ships. The result was, of course, that huge pieces of metal were broken out of all the important parts of the ships, and these pieces were thrown overboard.

Some of the German officers of these ships have declared, since the war, to Americans with whom they came in contact, that when they damaged these ships they thought they had made them impossible of repair. The fact that 9-ft. cast-iron cylinders could be repaired by welding seemed beyond their understanding. They stated that although the Germans had experimented extensively with all sorts of welding, they could not weld cast iron of such bulk.

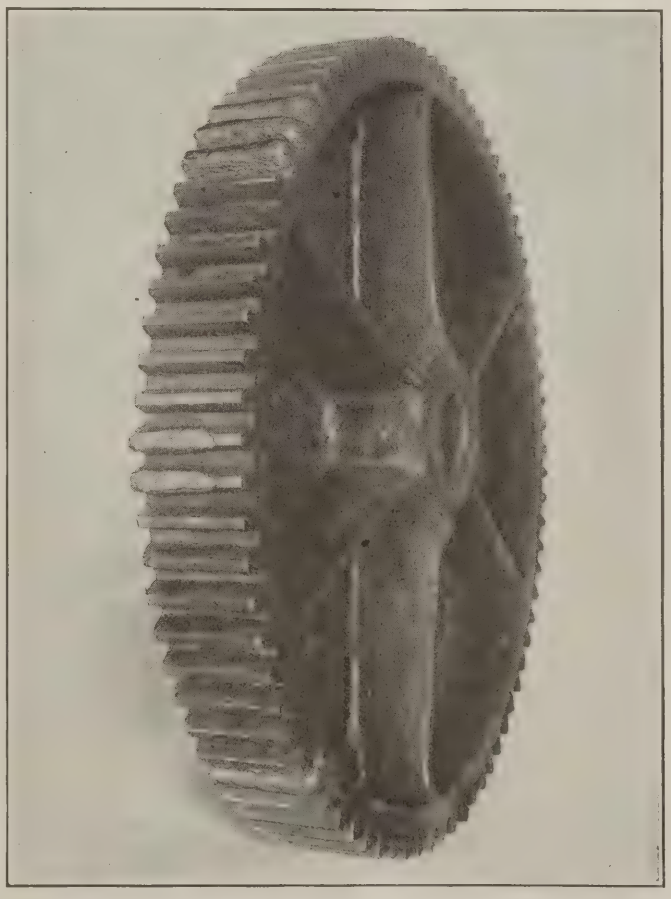
On the cylinders of the 20 vessels of German origin, exclusive of the turbine-driven "Leviathan," formerly the "Vaterland," there were 118 major breaks which would have entailed the renewal of some 70 cylinders if

REBUILDING THE PINION END OF AN ARMATURE

ordinary practice had been followed, as was the recommendation of the surveying engineers in their original report. However, a group of five electric-welding experts inspected the damage and reported that all the cylinders could be saved by welding. A fact of great importance to the marine engineering world is that all the cylinders were thus saved, the ships were quickly made serviceable and another calculation of our enemy was thereby sadly disarranged.

To any one familiar with conditions at that time in the machine shops and foundries in the vicinity of New York, also in the drafting rooms, the problem of producing 70 cylinders of the size required by these vessels would have seemed almost impossible, and it is fairly well established that some vessels would have had to wait nearly two years for this equipment.

It must be remembered that few drawings of these engines were available, and those in many cases were not discovered until months after the repairs had started. Therefore, it would have been necessary to make drawings from actual cylinders, and competent marine engine draftsmen who were not already flooded with work did not exist at that time.



The break in the starboard high-pressure cylinder of the North German Lloyd steamer "George Washington" was typical of the damage done by the Germans. This break was effected by boring a row of holes in the cylinder wall, about an inch apart, and knocking a piece of the wall out with a ram.

To prepare this for welding it was necessary to chisel off the surface roughly, build a pattern of the break, cast a steel piece from the pattern, stud up the surface of the cast iron of the cylinder with a staggered row of steel studs $\frac{5}{8}$ in. in diameter projecting $\frac{1}{2}$ in. from the cylinder, bevel the edge of the cast piece, place the piece in position, and make the weld. A pad of metal was sometimes laid over the rows of studs previously mentioned. Tests have shown conclusively, however, that such welds can be properly made without this pad; that is, if the approximate strength of the original metal is all that is desired. In such a case the studding of the metal is unnecessary. In these particular cases the work was of vital importance, because of the uses to which the vessels were to be put when in service. Furthermore, it was appreciated that this exhibition of a new application of the art of welding required that the demonstration be satisfying, not only to the mind of the engineer, but to the eye, and ear. And when any engineer looked at the band of metal formed by the pad and sounded it with a hammer, he could not fail to be satisfied that the necessary strength was definitely there.

Capt. E. P. Jessop, of the Navy, personally tested many welds in which cast iron was joined to cast steel for tensile strength and noted in but one case a failure to obtain practically the original strength. This one case showed the effect of an inexperienced operator burning the metal. It was easily detected as an inferior weld without the test being applied.

The electric-welding operation consists in connecting the positive leg of the circuit to the part to be repaired, and the negative leg to the holder in the hand of the operator, placing the welding wire in the holder and bringing it sufficiently close to the casting to strike an arc. The welding wire then melts to a plastic state and fuses to the casting, which is also in similar state from the heat of the arc. The metal is laid on in layers in such a manner as to take care of the contraction in cooling. Each successive layer is cleaned with a wire brush before the next layer is applied. In the keeping of the successive layers clean and in laying on the metal so as to take care of contraction the operator's ability is exercised quite as fully as in the handling of the apparatus.

The cylinders of the German engines were not removed, but were repaired in place. Thus the work of fitting was reduced to a negligible quantity, and the refitting of lagging was not interfered with by projections, other than the $\frac{5}{8}$-in. pad, which was laid over the studs for extra strength. It may well be noted that such repairs can be undertaken at any place where a vessel may be lying, either at her loading dock or in the stream, since welding apparatus may be carried on

RENEWING TEETH IN A DAMAGED GEAR WHEEL

barges which can be placed alongside and a wire run to the work.

In the early days of arc welding attention was directed solely to developing the machines employed in the operation and little thought expended on the welding metal itself, or how it should be used to attain the best results. The result was that a large percentage of the attempted welds were failures, principally because of the change in characteristics of the welding metal from the effect of the heat in the arc.

This particular phase of welding has been made the subject of special study by laboratory engineers, with the idea of developing a welding metal that would hold its proper characteristics through the intense heat of the arc. It was determined after long experiment that no one welding metal could be developed that would insure lasting holding qualities in work on a variety of metals.

The result was that a number of special welding metals were developed and these were experimented with, analyzed and further developed, until the special welding metals, known as Plastic-Arc certified welding metals, were finally evolved. These special welding metals, of which there are eight grades, are made up in the form of welding electrodes.

In order to insure proper tensile strength and ductility it is necessary that the welding metal possess the following qualities: (1) The wire must flow evenly with good penetration. (2) The metal added must compare favorably in its composition with the parent metal.

In welding with an ordinary soft iron electrode on a metal part that contains about 20 per cent. (so called) of carbon and 45 per cent. of manganese, the deposited metal is practically pure iron and does not penetrate the weld.

The parent metal is plastic for about $\frac{3}{16}$ in. below the surface and the electrode is added while it, too, is in a plastic state. When a sufficient amount of this incorrect welding metal has been deposited at a certain point, the operator moves the arc along and the metal quickly hardens, leaving a sharp line between the parent and the added metal. The result is a weld devoid of holding qualities or the tensile strength of the parent metal, and failure is certain to occur the first time undue stress is imposed on the welded part.

In order to insure a tensile strength as great as or greater than that of the parent metal, it is absolutely necessary that the welding metal be of such composition as to retain the characteristics of the parent metal after the welding metal has been passed through the intense heat of the arc.

In welding parent metal of about 18 per cent. carbon and 45 per cent. manganese, by the Wilson system, No. 6 welding wire is used. This contains 22 per cent. of carbon and 75 per cent. of manganese, together with a small amount of copper. Part of the manganese, some of the carbon and practically all of the copper are burned away in the arc, leaving the added metal with about 19 per cent. of carbon, 50 per cent. manganese and no copper, which is approximately the same composition as the parent metal.

THE COAL sample of higher moisture content will usually occupy more space for the same number of pounds of (dry) coal than will a sample of lower moisture content. However, the Bureau of Mines states that the increase in volume for the wet coal is not so great proportionately as is the increase in weight per cubic foot.

Tenth Annual Meeting of the Mine Inspectors' Institute

THE tentative program of the tenth annual meeting of the Mine Inspectors' Institute of U. S. A., which is to be held at Indianapolis, Ind., July 8, 9 and 10, 1919, promises to be most interesting and profitable to those who will attend. The headquarters of the Institute will be located at the Claypool Hotel, and meetings will be held at the Legislative Chamber, State Capitol Building, and the hotel proper. The ladies attending have not been forgotten, for they will be given the privileges of the parlors of the Claypool Hotel, and their entertainment will be in charge of a local committee.

As announced, the program is as follows:

TUESDAY, JULY 8, 1919

10:00 A.M., State Capitol—Address by Hon. James P. Goodrich, Governor of Indiana; Hon. Philip Penna, Indian Coal Operators Association, and Hon. William Green, United Mine Workers of America.

Response by members of the Institute.

Business Session—Acceptance of new members, etc.

2:00 P.M., Palm Room, Claypool Hotel—Address by the President, Thomas Graham.

Discussion.

Indiana State Mine Inspection Service, Its Aims and Hopes, by Cairy Littlejohn, Chief Deputy Mine Inspector of Indiana.

Discussion.

Address by Prof. C. J. Norwood, Chief Inspector of Mines for Kentucky.

Question Box and Discussions.

8:00 P.M., Smoker—

Round table conference.

WEDNESDAY, JULY 9, 1919

10:00 A.M.—Palm Room, Claypool Hotel—Compensation Insurance as an Aid to the State Mine Inspector, by J. G. Vaughan, District Mine Inspector of West Virginia.

Coöperation Between State and Insurance Inspectors. by H. M. Wilson, The Associated Companies.

Discussion.

Question Box and Discussion.

2:00 P.M.—A Method of Humidifying Coal Mines to Prevent Coal-Dust Explosions, by J. W. Paul, Mining Engineer, U. S. Bureau of Mines.

Discussion.

History of the Mine Inspectors' Institute of the U. S. A., by Prof. J. T. Beard, Senior Associate Editor, *Coal Age*.

5:00 P.M.—Automobile ride through Indianapolis, leaving from Claypool Hotel.

8:00 P.M.—Business meeting.

THURSDAY, JULY 10, 1919

Visit some Indiana coal mine, place of visit to be announced on July 9.

CARBON IGNITES at about 900 to 1000 deg. F. Therefore, in burning pulverized coke or anthracite in furnaces it is necessary to use special expedients to raise the temperature of the burning fuel above the ignition point. Low-volatile fuels have been burned satisfactorily by this method.

The Importance of Rail Bonding

By E. Steck
Hillsboro, Illinois

SYNOPSIS — *Locomotives often fail through no fault of design and no imperfection in manufacture, but through improper or inadequate electrical supply lines. The chief difficulty appears to be poor track bonding, which cuts down the voltage delivered to the mine motors. The welded terminal type of track bond appears to give better all around results than other common varieties.*

MANY coal operators and superintendents do not realize the importance of proper track bonding. Excessive numbers of and high maintenance cost on locomotives and cutting machines are often traceable to poor bonding. The full importance of this matter is not apparent until this subject is investigated in detail.

If the theory once expounded to me by an electrician in charge of a large mine were true, bonding would not be necessary. His view was that the trolley was the positive side, which carried the current from the positive brushes of the generator out along the line and into the locomotives and cutting machines. After passing these machines it made no difference what happened to the current, and no return was necessary. If by any chance the polarity of the generators was reversed, it would be impossible to operate the locomotives and coal cutters, as the current would have to flow along the rail, which, not being bonded, would make it impossible to reach the machines.

Of course, this theory is not correct. It is just as important to have good bonding if the trolley is the positive side as it is if the trolley is the negative side. In fact, it is generally highly important to bond properly since the voltage drop may thereby be made to be less over the rails than over the trolley. The voltage of any point in the mine circuit is readily calculable, since it depends upon the amount of current, size of trolley and feeder, rail resistance and the voltage of the generator.

$$\textit{Voltage drop} = \frac{10.5 \times \textit{amperes} \times \textit{distance}}{\textit{Circ.mil of conductor}}$$

For example: The generators on top develop 275 volts direct current, and we will assume that there is a 15-volt drop in the cables connecting the trolley and rails to the source of energy. The voltage on the bottom will then be 260. If the voltage at a parting 3000 ft. from the bottom is desired, when 800 amp. is being used on the entry, and there are 35-lb. 30-ft. rails with bonds showing an average of 4 ft. of rail resistance, and a 4/0 trolley with a 500,000-circ.mil feeder, the calculation is as follows:

$$\textit{Drop in trolley} = \frac{10.5 \times 800 \times 3000}{211{,}600 + 500{,}000} = 35 \textit{ volts.}$$

$$\textit{Drop in two rails} = \frac{10.5 \times 800 \times 3400}{371{,}360 \times 2} = 38 \textit{ volts.}$$

The resistance of the rails in the foregoing is assumed as 12 times that of copper, or the cross-section of 35-lb. rail equals 371,360 circ.mil of copper. A 4/0 trolley equals 211,600 circ.mil. In this case the bond has the effect of making a 30-ft. rail equal to 34 ft. on the basis of resistance; therefore, 3000 ft. of rail would be equal to 3400 ft. when bonded. In other words, the 35-lb. rail well bonded is as effective as a 4/0 trolley plus a 500,000-circ.mil feeder. The voltage at the parting will be 260 — 35 — 38 = 187 volts.

Now take the same condition where the bonding is extremely poor; no cross-bonding; switches not bonded; sections of track without bonds, and good bonding at only infrequent intervals. Under such conditions it is not out of the ordinary to find the average—that is, the total rail joint resistance divided by the number of joints—equal to 60 ft. of rail resistance. In this case the overhead drop will be the same, but the rail drop will be

$$\frac{10.5 \times 800 \times [3000 + (100 \times 60)]}{371{,}360 \times 2} = 100 \textit{ volts.}$$

The voltage at the parting will be 260 — (35 + 100) = 125 volts. The effectiveness is reduced to a little more than that of a 4/0 wire. The result is not only a frequent burning out of locomotive and machine armatures, but the slowing down of all electrically operated machinery. The locomotives will not make as many trips as they should, and the machines will not cut enough coal. It can readily be seen that this poor bonding reduces the output of the mine, and that when the bonding is done efficiently the locomotives will haul more coal and the machines will cut more places. Either the tonnage will be increased with the same amount of equipment or, if it is impractical to increase the tonnage, some locomotives and machines can be dispensed with.

We can easily see that a mine with good bonding saves in the number of machines and locomotives required for a given output. The reduction of the number of machines and locomotives reduces the capacity of boilers, engines and generators, decreases the amount of boiler coal necessary and, in fact, lessens the demand upon all power-plant equipment. There will be a saving in the number of motormen and tripriders that frequently amounts to considerable. There will also be an increase in voltage as the amount of current will be decreased, and from the formula it is noted that the voltage drop is directly proportional to the amount of current required. The cost of bonding, including labor and material, when done well is small in comparison with the benefits derived.

The bond resistance depends on the length of the bonds and the type. A 12-lb. high-carbon rail has practically the same resistance per foot as a 2/0 copper wire; a 20-lb. rail is equal to a 4/0, and a 40-lb. rail is equal in resistance to two 4/0 wires. Main haulageways should have both rails bonded with 4/0 wire where haulage motors, gathering motors and cutting machines are in use. This is especially necessary in old mines where the partings are far back from the bottom. In cross entries it is generally found efficient to bond one rail with 2/0 bonds; however, if some of these cross entries are to be used later as main haulageways, they should be bonded with 4/0 bonds on one rail, and later the other rail may be similarly bonded. It is not

possible to give an empirical formula for bonding, but after the length of bonds has been decided upon their size should be such that when the mine is fully developed the drop will not be excessive.

Often a piece of solid wire is laid along the flange of the rail and clamped to it by spikes driven into the ties, so that the head of each spike presses the wire to the rail. Tests made on 20-lb. rail with 2/0 wire show about 6 ft. of rail resistance when the wire and rail are both clean and the bond has just been installed. A test two months later showed 25 ft., and in six months this bond was found absolutely useless. The apparent explanation is that the locomotives loosen the wire, and the rust on the rail and the oxidization of the copper gradually increase the contact resistance.

Channel pin bonds are a development of clamp bonds with all their troubles, only these take longer to develop. Compressed terminal bonds are and remain effective when properly installed, but it is nearly impossible to have them put in as they should be. In many instances the head of the terminal is too short, making it impossible to do a good job. More often the bond hole is not the correct size for the bond, the hole is not cleaned thoroughly, oil, dirt and dampness being present, and the bond compressor is not used properly, or a hammer is employed in place of it.

With poor workmanship the bond resistance quickly increases and the bond becomes ineffective. Tests made at the time some 4/0 compressed terminal bonds were installed on a 25-lb. rail showed an average resistance equal to 4 ft. of rail. In less than a year this had increased to 15 ft. because of poor workmanship.

How the Hole Should Be Reamed

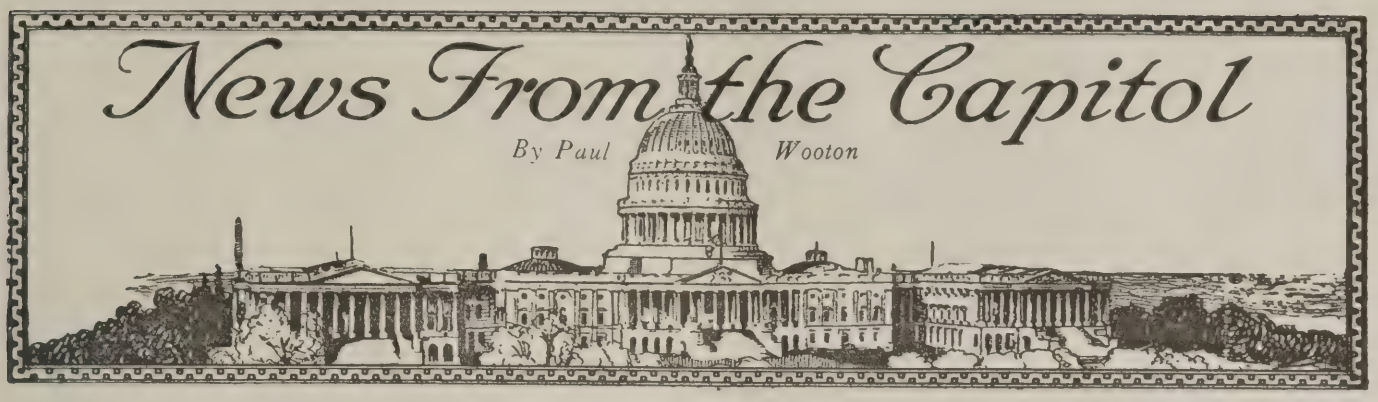
In order to obtain permanently satisfactory results with this type of bond the hole should be reamed with a taper reamer to such an amount that the bond must be lightly tapped to cause it to enter the hole. Both sides of the web of the rail should be surfaced; all dirt, oil and moisture should be thoroughly cleaned off before the bond is inserted, and a bond compressor should be employed. The head of the bond should be of sufficient length so that a button is formed after it is compressed.

Because of the trouble encountered in getting these bonds installed properly, electrically welded bonds are coming into use. The cost of these bonds is practically the same as those of the compressed terminal type, but the cost of installation is decidedly less. Experiments further show that a bond of this type is permanent.

These bonds may be procured with either iron or copper terminals. While the copper has slightly less resistance than the iron terminal, it is more difficult to weld to the rail. Bonds are made for welding to the ball, web or flange of the rail. A short U-shaped bond is used for attachment to the ball. This has the advantage of being cheap and easily inspected, but it car only be used on heavy rails with tight fishplates and where the ties under the rail joints are in good condition. Otherwise such bonds will be cut off.

The same bond can be used underneath the flange, but one serious objection is that it cannot here be inspected readily; also on old track generally the ties must be changed. This makes the cost prohibitive. The most satisfactory method for the average track is to use the straight bond, 10 in. longer than the fishplate, and weld it to the upper side of the flange on the inside of the rail so that it passes just underneath the bolts. This method gives maximum protection in case either cars or locomotive leave the track, and it can here be easily inspected.

The objection to using this type of bond and welding to the rail web is the liability of burning the web and damaging the rail. With a gang of three men, one to do the welding and the other two to prepare for the weld, 15 to 20 bonds may be put in place per day when all hands are absolutely new to this work. With about two months' experience they can easily put in 60 per day. This is on an eight-hour basis and must take into consideration the fact that work is often interrupted to permit the passing of locomotives. The average for putting in concealed compressed terminal bonds under like conditions is about 15 per day for two men. On a test using 35-lb. rail and 28-in. 4/0 bonds of the welded type, the installation gang showed an average of 100 bonds per day. A test made a few months later showed no change in resistance.



Importance of Bonding Switches

Even when bonds are properly installed it is important that the bonding progress with the track extension and that relayed track be bonded at once. In many instances considerable trouble is taken in bonding a straight track and no attention paid to switches. Special precautions should be exercised in bonding switches, as neglect to do so, especially where there are no cross bonds, is to make the work done on the straight track useless.

The advantage of cross bonding is that should a rail joint have especially high resistance because of a defective bond, the current will take the other rail on the cross bond just before this fault, and again return on the next following cross bond. Consequently, cross bonds should be installed about every 200 ft. They should be about 10 in. longer than the gage of the track and should be buried in the ground close to a tie in order to protect them from injury.

Return feeders frequently are placed along the track and only tied to it at the end of the feeder. The effectiveness of the feeder will be greatly increased if it is tied into the track about every 200 ft. This materially decreases the length of the electrical circuit as the locomotives come into the bottom; or, in other words, it increases the voltage at the locomotive. Care should be taken to solder the feeder and either weld the other end to the track or bond to it by means of compressed terminal bonds; cross bonds cut in half are convenient for this service.

In proving a coal property preliminary to development, often a number of drill holes are put down which serve their usefulness when the desired depth has been reached and a record obtained of the material drilled. Later when mining has opened up territory including these old drill holes, it often happens that they increase the amount of water to be pumped. The old drill holes may have gone through crevices, fissures or seams of watery strata, and it is desirable to stop the flow into the mines. A number of methods have been used to plug such drill holes, operating from the surface. However, a simple method of plugging the hole from the underground workings is as follows: Fill small bags with concrete and push them up into the hole one at a time, the diameter of the hole determining the size of the bag used, as ultimately they must be wedged tightly into the drill hole. When no more concrete can be forced into position the bottom of the hole is plugged with a soft pine stopper, which can be supported temporarily in position until the concrete sets.

Navy Rejects Bids for Steam Coal

The Navy has rejected all bids submitted for steaming coal for the coming fiscal year and is continuing its requisition of coal on a pro rata basis at a price of $3.08 per gross ton. Some question has been raised as to the authority of the Navy to secure coal in this way after the signing of the peace treaty. Some operators are of the opinion that the Navy made a mistake in not accepting the bid, since the operators, under the requisition plan, may sue if they are not satisfied with the price, and it is believed that the Navy will pay a much larger amount for its coal than would have been the case otherwise. In connection with the refusal of the bids, Secretary Daniels issued the following statement:

Failing to secure tenders of enough coal to fuel the troop ships bringing the Army back from abroad, the Navy has found it necessary to provide an adequate supply of satisfactory coal, primarily for use on vessels engaged in the return of troops and other purposes afloat, to continue the issuance of Navy orders, as is being done in the case of current deliveries.

Under a recent issue of proposals soliciting competition for the furnishing of steaming coal after July 1, definite offers were received for only about one-half of the quantity requested, some of the largest operators offering only a meager supply and some having failed to submit a bid.

At Hampton Roads and New York, two of the principal points of supply, the tonnage as offered was less than one-half and one-third respectively of the estimated requirements.

The coal situation, as reflected in the Navy's recent bids, is viewed as rather difficult of explanation in that recent announcements from persons active in the interest of coal supply have indicated that the reluctance of consumers to buy coal was resulting in more or less concern to the operators, as an increase in demand was needed to provide employment for the miners and the desired increase in production.

The Navy orders just issued will cover the period for six months from July 1, and for the most part provide for prices which are in keeping with the lowest bids received for high-grade coal under the schedules recently published.

Hearing Ordered on Coal Rates to Northwestern Ports

The Interstate Commerce Commission has issued the following statement in the matter of rates on coal to northwestern points:

Whereas, the Director General of Railroads, in exercise of powers conferred upon the President by Section 10 of said Federal control act, increased the rates on coal from mines in Ohio and West Virginia via the lakes to points in the States of Minnesota, North Dakota, South Dakota and the northern portion of Wisconsin by 52c. per ton from such mines to the lakes and by various additional amounts from the western lake ports to the points of destination, while the rates on coal from mines in Illinois and Indiana to the same destination territory were increased 55c. per ton, and

Whereas, the Director General of Railroads has received numerous complaints, particularly from dock operators on the lakes alleging that the increases in the rates from Ohio and West Virginia mines disturbs the relationship theretofore existing with the Indiana and Illinois mines and that this change in rate relationship will seriously restrict the shipment of coal via the lakes, and under Section 8 of the Federal control act has requested the advice, assistance and coöperation of this Commission in the premises:

It is ordered, that the Commission enter upon an investigation into and concerning the relationship between the rates on coal to Minnesota, North Dakota, South Dakota and the northern portion of Wisconsin from mines in Ohio and West Virginia, via the lakes, and the rates on coal to the same destination territory from mines in Illinois and Indiana, all-rail, with a view to advising the Director General whether the relationship heretofore existing between the rates from the Indiana and Illinois mines and the rates from the Ohio and West Virginia mines should now be restored; and if so, in what manner the restoration should be accomplished.

It is further ordered, that this proceeding be, and it is hereby, assigned for hearing on June 25, 1919, ten o'clock a.m., at the office of the Interstate Commerce Commission, Washington, D. C., before Commissioner Clark.

Bureau of Mines Specialists Complete Investigation of Lignite

O. P. Hood, who has charge of the lignite investigations being made by the Bureau of Mines, has returned from an inspection trip through the North Dakota lignite fields greatly impressed with the immensity of the beds of brown lignite in that state. War conditions have stimulated the use of North Dakota lignite until it now is being used at the rate of 1,000,000 tons annually, Dr. Hood finds. He also is impressed with the fact that the average citizen in North Dakota is taking a serious interest in lignite and is willing to do all that lies in his power to make use of it for his every day personal needs.

The great problem which confronts the development of lignite in North Dakota is the finding of a market for the gas which is the principal byproduct of lignite preparation.

Dr. Hood and Bureau of Mines specialists now have completed their studies of the two great lignite fields of the country and soon will make a recommendation as to which is better suited for the establishment of the Government's experimental plant.

EDITORIALS

Mine Inspectors—Attention!

JULY 8 is to be the Grand Rally Day of the mine inspection forces of America. After an interim of three years, following their last gathering at Joplin, Mo., in 1916, the Mine Inspectors' Institute will hold its decennial meeting, this year, at Indianapolis, where the first conference of inspectors was held and the Institute organized, in 1908.

It had been expected to hold this decennial meeting at the regular time, July, 1917, but loyal to the country's call for increased output of coal, the executive board voted to postpone further meetings of the Institute to a time when inspectors could be better spared from their duties at the mines.

That time has now arrived and, although there is much labor unrest among mine workers, which demands the intelligent advice and coöperation of the inspectors in all mining districts, no better preparation for these duties is afforded than the coming together of the inspectors from all parts of this country and Canada to discuss such questions of mutual interest and benefit.

Let every mining department or bureau, every inspector and assistant inspector, in the United States and Canada bring this matter to the attention of their governors or other authorities at once and obtain their authorization for attending the Indianapolis meeting, July 8-11, 1919.

Each state and province should see that a good delegation of its inspectors attend the meetings and become members of the Institute. The expenses of inspectors in attendance should be met by their respective states or provinces, as the benefit derived from such gatherings is vast and important.

Attendance at the meetings is always open to all state, district or county mine inspectors, assistant inspectors and Federal commissioned officials engaged in the work of coal and metal mine inspection and investigation, in the United States and Canada. All are invited to become members of the Institute. The membership includes both coal and metal miners. Many ex-inspectors still retain their membership under special provision of the constitution.

Arrangements will always be made for the entertainment of the wives and lady friends of members in attendance at the meeting and it is hoped a large number of ladies will be present this year.

Let every inspector, then, get busy and *boost, boost* and *boost again,* for Indianapolis, in July. It is the old stamping ground where the Institute first saw the light. Rally to the high standard of efficiency in mine inspection.

South and Central America, while largely fuelless, produce bananas, coffee, mahogany, rubber, hides, platinum, nitrates and tin, materials for which we have much need. The coal trade, therefore, with South and Central America is as logical as is our trade with Canada. "See it grow!"

A "Mute and Inglorious" Profession

PERHAPS the engineering profession prides itself, in the words of Grey's "Elegy," on being mute and inglorious. Certainly our engineers are not good speakers. For the most part they do not impress the public in an interview, and they certainly do not distinguish themselves before an audience.

Muteness and ingloriousness quite generally go together. No wonder the lawyers pull down all the big jobs, the managerships, vice-presidencies and presidencies of our institutions. Those learned in the law can stand on their feet unabashed. They can argue their point of view, whereas the engineer—civil, mining, mechanical or electrical—surveys his shoes rather than the world in general and diligently digs into the depths of his pockets for stray coins the feel of which will ease the agony of his mind.

The engineers are looking up and looking over, and the lawyers who have talked expansively about nothing in general and about all things but the body of the fact in particular will have to give way. The big engineers' societies are now planning to give the professional man his proper place.

The years behind affect us more than we know. The engineering profession is one of the most recent of all. The recognized order of precedence has been the army, the church, the law, medicine and engineering. Fermentation in the politic mass is making changes in this long-established order, and the engineer is coming bubbling to the surface.

But all this change will not come about if reticence and silence, obsequiousness and indecision, are to be marks of the engineer in the conduct of his professional life. He has the knowledge which justifies confidence, and he should not leave to those who lack the wherewithal for management full possession of the field.

Some day our colleges will put out engineers who can write and who can speak, who can awaken in others the confidence that the possession of a collegiate education should inspire. The college will not only sharpen the nail but provide the hammer by which it can be driven home. *Coal Age* intends to give space to those who are trying in all engineering fields to put big engineers in the place where they rightly belong.

South America must not be rated by what it is but by what it will be. We must remember that in some respects it is like Seward's Alaska, a country of unknown and untold possibilities.

Further Steam-Shovel Possibilities

THE opportunity to mine coal with the steam shovel is not limited to the regions where the coal in general is under light cover. In the anthracite region the cover is heavy, yet here steam shoveling for coal first had its origin. The work is done only at the crops, and, as the seams are thick, the cover removed is often

of great depth. In fact the material to be transferred is so large in quantity that locomotives and dump cars have to be installed to remove it.

In the bituminous regions of Pennsylvania are miles and miles of coal crops, many exhibiting themselves in the poorest ground, which is often entirely untilled. As the coal enters the hill on a level it is possible to secure a large amount of mineral without much excavation. As nearby there is plenty of room for spoil, there need be no need for double shoveling. The shovel will drop the coal cover over the valueless wash crop and down the slope of the hill.

Many of the earlier mines left all the crop coal underground. The roof was bad. The coal was apt to be discolored, while nearby there was an abundance of bright, hard coal with a good roof. For this reason the crop coal was left. But in many of these regions croppy coal is now being worked, and it would appear that much real Moshannon coal (Lower Freeport or "D" bed) for instance, could in that way be obtained. It would doubtless be a little rusty in places, but in all probability it would be somewhat lower in sulphur than the bed under heavier cover. There are many other sections, some of them mining coal just as good as the Moshannon and almost as badly depleted, where similar work might be done.

The benefits to be derived along the crop are not limited by the extent of the output uncovered by the shovel. In many cases pillars have been left in the workings as they approached the crop and these, being laid bare and being approachable owing to the work of the shovel, can be operated without much expense by underground methods. In fact it will probably be found that where there are revealed a hundred approaches to a mine through solid coal many old and imperfectly operated areas will be again made centers of activity.

It is much simpler to take out a pillar or pillars and thus enter an old mine than it is to clean up the falls in an abandoned heading. Given a free approach to a lot of pillars leading to the surface, there is always a chance of excavating a large area of coal. Without this means of approach one might not be able to profitably recover the coal lost in the mine.

In the anthracite region the old practice in stripping needs a new birth. The dinkey shovels, locomotives and dump cars need replacing with more modern and larger equipment. There are some signs that a change in viewpoint is coming and that excavations so large as to bring up recollections of the Panama Canal will cease to be conducted with such inadequate equipment as these old strip-pits exhibit.

Mules and horses are rapidly finding that their bad manners and low energy output are ousting them from the mines. But they seem to be holding on better on that part of the colliery work which is performed on the surface—why, it is hard to explain. The motor truck is as logical as the mine locomotive, but so far no one has come forward to present its case to the coal operator.

French Miners Strike for Short Hours

WHEN there is a shortage of coal, of provisions, of everything that makes home happy and endurable, the French workingman strikes for a shorter day. His British brother is no better; in fact he is worse, for he did it first and was even more peremptory.

The workingmen of Europe are tangling themselves in a net of their own weaving. They have had a long period of fighting. As far as the national well-being is concerned they would have done better if they had taken a four-year holiday. Perhaps even a ten-year vacation would be better than four years of war. The war was far more exacting than any work, and it was for causes infinitely more worthy than those which impel us to our daily labor; but these considerations are beside the mark, and it is fair to say that the evil effects of the war may be not inaptly compared to the outcome of a holiday of from four to ten years.

After such a vacation we would expect the nations of Europe to buckle to their task. "Here is devastation," we might anticipate them saying: "here are delayed purchases; here is lack of needed material; let us work diligently to obliterate the effects of the dislocation of effort." Instead the workingmen are going back with a resolution to do less than ever, and the bourgeoisie are disposed to lengthen their week ends till they meet in the middle of the week. What can become of such a mental attitude!

One would think that among the beneficent discoveries of the war must have been one for performing work without toil, and really, the government boasts would lead us to believe it was so. But we have no record of any such discovery. The world is little bettered by war inventions and apparently is on its way to be beggered by the war psychology and the dreams that the war had painted. The rich now bleat about shorter hours and better living for the workingman. It is well perhaps that thoughts like these replace that old feeling of the bourgeoisie that the workingman should never vulgarize the pleasures of the middle class by his participation in them. But all the goodwill toward the workman will never result in the amelioration of his lot unless both employer and employee are willing to do their uttermost to produce and again produce.

If the mine worker in France or Great Britain worked eight hours before the war, he should do so now. If there is to be any change, he should work even longer hours, till the need of the European allies for coal is fully satisfied. The great holiday of destruction, death and pain is over, and the time for laborious peace efforts has arrived. The European people will prove their mettle if they keep their "home fires burning" by steady toil.

In the United States there is more excuse for the shorter day, but we do not believe that seriously the workingman will want it when he realizes that it will be accompanied by small output and therefore by less remuneration. Our vacation of blood was shorter. It was only accompanied by waste and not by destruction. Our future and even our present is reasonably assured, but it will be a three-quarter future only if we are going to reduce our hours by one-quarter. If, on the other hand, we seek the "simple life" and resolve to cast off the excrescences of civilization, we can have our leisured ease; but if we would hold the prosperity that we have, let us arrange to spend as much time on its securing as we have in the past.

The American Federation of Labor, at its Atlantic City session, would have the teachers' opinions unhampered by boards of education. Then, with questionable consistency, it advocates that its own "unbiased" view of "industrial history" be taught in the schools.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

No better evidence of the new alignment toward labor can be found than the report issued by the United States Chamber of Commerce in relation to its labor referendum. The report is dated June 22. The members of the Chamber of Commerce approved by a majority of more than two votes to one all the articles but No. 13, which was a proposal to establish a national employment system. The report chronicles the decision of the members that "the public interest requires adjustment of industrial relations by peaceful methods."

The members likewise recognize "the right of workers to organize," "that industrial harmony and prosperity will be most effectually promoted by adequate representation of the parties interested" and that "industrial-relations agreements should be faithfully observed."

The other declarations are that wages should be "reduced only when the possibility of reduction of costs in other directions has been exhausted," "that every man is entitled to an opportunity to earn a living wage" and that "wages shall be adjusted with due regard to their purchasing power." Fixing of a basic day as a "device for increasing compensation" is declared by the members to be a "subterfuge that should be condemned."

British Board Would Have Nation Own Mines

No one, for a moment, expected that the majority report of the Royal Coal Commission in Great Britain, appointed under the Coal Industry Commission Act, would fail to recommend nationalization of that industry in Great Britain. There will be a natural tendency toward a similar attempt here, though it does not necessarily follow that nationalization will be imposed on the industry. The continent of Europe and Australia had previously owned railroads for years, yet Great Britain resisted, as also did we, that costly experience—in fact, both nations took counsel from the unfortunate foreign examples and determined not to follow them.

However, though Great Britain has resisted many tendencies toward national ownership, through its coal commission it now seems to be committed to mine nationalization. It is true there are four reports filed by the commission, representing as many points of view, but the most numerously signed report, dignified with the signature of the chairman, Justice Sir John Sankey (a former judge on the Kings Bench and prior to that a barrister who had a large practice in mining cases) is whole heartedly for the taking over of the industry by the nation. That report recommends immediate legislation for the acquisition of the mines, royalties for the state and compensation for mine owners. The provisions of the report call for the administration of the collieries during a period of three years by local, district and national mining councils. At the close of that time legislation will have been framed for the acquiring of the mines and the owners will have been justly compensated.

Miners Object To Compensation of Land Owners

The miners' representatives in general agree that the report signed by Justice Sankey is satisfactory, but they object to a clause that would require the mine workers to sign a contract to cease work until any question that may be in dispute has been before the appropriate councils. The three representatives of the miners, Robert Smillie, president of the Miners' Federation of Great Britain; Frank Hodges, secretary of the same organization, and Herbert Smith, president of the Yorkshire Miners Union and vice president of the larger federation, declare in their report that no compensation should be given, apart from certain allowances made where small royalty owners are deprived of their livelihood.

The mine owners in their report argue that any form of nationalization would be detrimental to the development of the industry and the economical life of the country. The document declares that no action which so vitally affects the business of the whole nation should be taken without referring the question to the whole community. The report favors, however, the formation of a department of mines to be assisted by a system of councils such as the majority report sets forth. In order that the difficulties arising from royalties may be met, the operators' report proposes that the state acquire ownership of the coal subject to the continuance of existing leases for at least 60 years.

Sir Arthur Duckham, the Director General of Aircraft Production, makes the fourth report, recommending state acquisition of the entire mineral rights and the establishment of a Ministry of Mines with representation of labor on the directorate.

Mine Workers Urge a Reasonable Contract

On June 15 a secret session of past and present chiefs of the United Mine Workers of America was held at Atlantic City, N. J., at which were present John Mitchell and John P. White, former presidents of the organization; William J. Ryan, former international secretary-treasurer, now representing the National Fuel Administration at Kansas City, Mo.; J. L. Lewis, vice president of the United Mine Workers; John Moore, president of the Ohio district; Philip Murray, president of the Pittsburgh district; William Green, national secretary of the United Mine Workers, and a number of others. Little was learned of the business transacted. John L. Lewis said, according to newspaper reports, that "an orderly, sensible policy applied in a practical manner is what we have decided upon."

"I am not in favor of anything at this time that would disrupt reconstruction of industrial matters," said John Mitchell after the conference. "But the employers must remember at this stage of the situation that labor has some rights that should not be forgotten, but be recognized more than in the past."

On June 23, the American Federation of Labor, which met at Atlantic City, declared itself in favor of a universal 44-hour week in industry and pledged support to unions that were planning for a 6-hour day. It also called for double time as a penalizing measure.

Green Still Advocates the Shorter Day

Delegate William Green of the United Mine Workers said that the organization he represented intended to press for a workday of less than 8 hours in order to keep all the unemployed in the industry busy. He said that, with an 8-hour day and 100,000 men less than the industry had under the longer day, the coal mines had produced the greatest output in the history of the industry.

It may be said in this connection, in opposition to what Mr. Green has stated, that the shortage of coal now assures work to every one, and the shorter day should go over to a later time, if it is ever to be put in operation. The shorter day will never guarantee steady work unless there is a restriction in the number of new mines or additional workers. The agreement for a shorter day will be a signal for a large expansion in the industry such as will make it necessary either to work irregularly or to work still shorter hours. If the shorter day is introduced and the public runs short of coal it will know where to place the blame.

In the anthracite region a few troubles have recently occurred. The Hudson Coal Co. disaster stirred up the men, and, for a short while, there was a feeling that the company would try to find a means by which it might avoid

the payment of compensation losses. However, the minds of the men were soon disabused, for the chief counsel of the coal company, H. J. Torrey, of Scranton, lost no time in declaring to H. A. Mackey, of Philadelphia, chairman of the Workmen's Compensation Board, that the casualties were compensable. As fast as each case came up, the company disposed of it in a liberal spirit, as the statement by Mr. Mackey on June 14 clearly shows:

"Reports received from officials assigned to Wilkes-Barre to arrange for immediate compensation for the surviving injured workmen and the families of the deceased victims of the mine disaster in the Baltimore tunnel shows that with a few minor exceptions every claim has been settled within the last week. There were 92 deaths in the catastrophe, and 43 men were injured. The survivors of those killed include 40 widows, 106 children and 10 dependent parents. The agreements for compensation will average $4028.65 per claimant. The cases not settled include a dozen in which the dependents are residents of countries which are at war with the United States. These claims will be placed for the present with the federal custodian of alien property. The immediate settlement of claims, under the provision of the compensation act, has been due chiefly to the broad spirt of the Hudson Coal Co. and the remarkable efficiency of its compensation department. The company did not quibble, but leaned to the other extreme in its efforts to rush compensation along.

"The company established offices upon its own ground for the use of board officials while they were arranging the compensation agreements and even utilized automobiles to bring the dependents to these headquarters. In less than a week's time the entire problem of securing compensation for the victims has been solved, and another valuable demonstration has been made of the prompt action secured under the compensation act as contrasted with the delays and losses that occurred under the old laws."

However, the agitation did not end when full compensation was made. At the mines of the Hudson Coal Co. there has been, for some time, a claim for back pay aggregating $50,000. It has relation to the presence of slate in the coal which slate has to be removed. The miners have claimed consideration for this impurity under the scale as officially interpreted by the conciliation board. The men threatened not to go to work on Monday, June 23, if the questions at issue were not settled satisfactorily by Sunday. Claims for about $14,000 remained unsettled on that day, and the miners agreed to give further time for their consideration.

If the plan of the mine workers had been carried out 28 collieries would have been closed down between Forest City and Plymouth, and 11,000 men would have been laid idle. The difficulties appear to have reference solely to the conditions in the Clinton and Crystal Collieries. The settlement is a matter for congratulation, as the Hudson Coal Co. has shown itself, at least in recent years, quite anxious to advance the interests of its employees and its steady goodwill should by this time have begun to show results. Unfortunately it has, in places, a number of men who are never happy unless they can find excuse for trouble.

Another anthracite strike is that at the mines of the West End Coal Co., where on June 12 1500 mine workers were idle trying to settle by a strike what their agreement declares must go to the conciliation board. The agreement fails of its purpose if it does not end strikes.

Speaking at Wilkes-Barre, at a meeting in memory of the men who died in the Baltimore tunnel disaster, William Green, the secretary-treasurer of the United Mine Workers, denied that the mine workers would strike in sympathy with Thomas Mooney, though they greatly desire to see him freed. The plan of the Industrial Workers of the World was for all workers to strike five days at the beginning of each month, the abstention from work to continue till Thomas Mooney was liberated. The first strike was to commence July 1.

Mr. Green advocated in his speech to the mine workers that 66⅔ per cent. should be the amount of compensation provided and that no worker should be required to wait two weeks before drawing compensation for injuries received at his work.

In western Pennsylvania two strikes have been settled. It will be remembered that there was a suspension at the McFetridge Coal Co.'s mine, at Creighton, involving about 200 men. They quit on June 2 owing to a disagreement with the company. The mine, which has run nonunion for more than 20 years, is now to be a union mine, arrangements having been made to incorporate it into District No. 5, in which it naturally belongs, being in Allegheny County. It was announced June 12 at the headquarters of the United Mine Workers in Pittsburgh that the Bessemer field in which the McFetridge Coal Co. operates is now entirely unionized with the exception of one concern and even there negotiations are pending.

A report under date of June 11 states that Vesta No. 5 of the Jones and Laughlin company, located at Fredricktown, has returned to work after a strike of 8 weeks regarding the allocation of a house to a man who had left the service of the company and moved temporarily elsewhere. The strike caused a movement in sympathy at Vesta No. 4, located at California, Penn., and strange to say this mine was still striking after Vesta No. 5 had composed its troubles.

In West Virginia there are no strikes in the coal mines, as far as the news reveals, but there has been a strike of the employees of the motive-power department of the Norfolk & Western Ry. about the discharge of six men at Wilcoe. This has prevented the operation of many mines.

However, at the call of the first shift on Monday morning, June 16, after a strike of over one week, the striking employees returned to work in consequence of an agreement made between representatives of the American Federation of Labor and officials of the Norfolk and Western Ry. During the life of the strike, which began June 4, time freight was moved only after the greatest delay. The movement of west-bound freight was much curtailed and east-bound business was almost at a standstill. In the block mines of Indiana there has been a strike. Two hundred coal miners employed at the Franklin-Tandy-Low mine, west of Brazil, struck June 16 when the company ceased giving a bonus of 6c. a ton. The miners, who have been receiving 90c. a ton, say the extra 6c. was paid for leaving a strip of coal on the roof of the mine to support the roof and keep it from falling. The company, in rebuttal, says that the extra money was a war bonus. The matter has been taken up by officials of District No. 11.

JOHN MOORE, president of the Ohio miners, delivered himself as follows in a recent statement to the press: "In eastern Ohio, practically adjacent to the Pittsburgh district, a few months ago there was idleness in Belmont, Jefferson, Guernsey, Tuscarawas and Monroe counties. Our men were getting impatient and I might say to the revolutionary stage. Today they are all working and the coal operators are clamoring for more men. From the records kept in our office about 14 per cent of the foreign-born miners in southern Ohio have asked passports to go home with the little wad they have made during war times when things were flush. This means a decrease in man-power. It means also a shortage of the supply of coal during the fall and winter months. This is no time to throw a monkey-wrench into the industrial machinery of the country which is being gradually greased. Let everybody get on the job to have things going good and proper."

Don't Carry Powder on a Man Trip

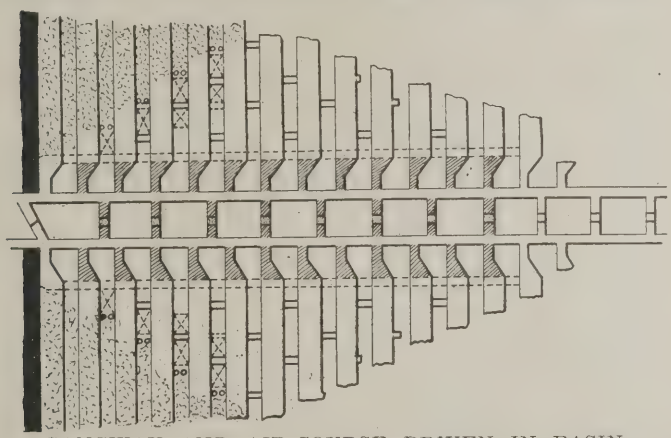
ON June 5 an explosion in the Baltimore Tunnel, at Wilkes-Barre, Penn., resulted in the death of 92 men, the widowhood of 43 wives, the making of 106 orphans, and the bereavement of 10 dependent parents. Among those who paid the price for negligence and carelessness was the father of the family shown in the photograph. The more we study the picture, the more we realize that the living are more in need of our tears than the dead.

THE father of this family may not have been a careless man—the look of his family suggests that he was a more than usually good citizen—but because there were careless men with him, and because there were men who did not observe the union rules and agreements as to carrying powder with them on the man trip, he died a terrible death, leaving a widow and seven children.

What Precautions Are You Taking to Protect Yourself and Family and the Families of Those Who Ride the Cars With You?

DISCUSSION BY READERS

EDITED BY JAMES T. BEARD



Drawing Pillars on Steep Pitches

Letter No. 1—I have been much interested in reading the inquiry signed "Luzerne," *Coal Age*, May 15, p. 924, because I had a similar experience some time since in taking out the coal in the "Pittston" or "Cooper vein," in this county. If I mistake not, the inquirer whose case is here presented, is operating in the same vein and, if so, the suggestions I have to offer may be of some assistance to him.

First, then, let me say that my friend's trouble may arise from too small a thickness of pillar left between the gangway and the airway, both being driven in the basin, from which the coal pitches on each side from 35 to 45 deg. My experience is that, as a rule, no squeeze will start in the chambers owing to the coal lying on this pitch.

In my case, it was necessary to temporarily abandon the airway in the basin and to start a counter, about 40 ft. above the airway on the pitch. This counter was driven parallel to the airway and, as it crossed each chamber, the mouth of the chamber below was filled solid with rock, from the airway up to the counter.

In the accompanying sketch are shown the gangway and airway driven in the basin and the chambers

GANGWAY AND AIR-COURSE DRIVEN IN BASIN

driven to the pitch on each side of these entries. The counter is indicated by the dotted line and the rock filling the mouth of each chamber is shown by the hatched portion between the counter and the airway. Moreover, as shown in the sketch, each crosscut between the gangway and airway was filled solid with rock, in the same manner as the chambers.

The coal was 14 ft. thick and overlaid with a solid sandrock roof. In each chamber, a line of props was set 8 ft. from the rib, the timbers being 20 ft. apart. Old wooden rails were then spiked to the bottom of each prop. Also, two or three props were stood just behind the pillar being drawn, and old rails or lagging were nailed to the back of these to protect the workmen against loose material falling down the pitch.

This arrangement had the effect to protect the slide or chute at the side of each pillar. When a cave occurred, the loose material was deflected so that it did not obstruct the chute and interfere with the loading of the coal, which ran down to the battery erected near the mouth of each chamber.

In the drawing of the pillars, narrow cross-headings were driven through each pillar at distances of 14 ft. apart, thereby dividing the pillar into separate stumps, which were blown out in one operation by drilling several holes to the center of the stump and charging and firing these holes by an electric battery.

As each two pillars on opposite sides of the main roads were finished, the chamber stump and gangway pillars were taken out. By that time, the rock filling previously mentioned had become so solid that the roof did not cave when taking out these pillars. To this day, one is able to walk through these places where the pillars used to be. It is, of course, not 14 ft. in height, but the headroom is sufficient to take an empty car along the road.

RICHARD BOWEN.

West Pittston, Penn.

Safety in Mine Timbering

Letter No. 2—While there are many good points brought out in the letter of Jesse Hamilton, *Coal Age*, May 15, p. 919, and in the previous article to which he has referred, written by Joseph R. Thomas, Feb. 20, p. 349, I feed that they have failed to mention a method of supporting the roof on haulage roads that, to my notion, is far superior than any form of timbering that can be adopted.

It surprises me that Mr. Hamilton, who formerly had a great deal to do with this method, which was then in use on the main haulage road in a certain mine here and which has since proved to be the best and most practicable means that I have ever seen adopted for that purpose, should have omitted to refer to the method in his letter.

USE OF IRON RAILS TO SUPPORT ROOF

In that mine, it was the practice to use the discarded rails as roof supports set 4 ft. apart and hitched into the rib on either side of the haulage road. The work was well done and certainly looked practical. The use of rails, instead of timber crossbars gave a good, clear headroom on the road.

In speaking of the number of accidents due to falls of roof, it is noticeable that there are far more of such accidents occurring at the working face than on the roadways in the mine. This may be due to several causes. For instance, the men remain a much longer time in their working places than they spend in traveling the roads. Also, a bad piece of top on the road is observed by the many men passing in and out of the mine, while a bad roof in a working place is seen only by the few men who go into that place. But safety on the haulage roads is as important as at the working face.

In the use of iron rails in the manner I have mentioned, the risk of timbers being knocked out by cars

jumping the track is avoided, and this alone is a strong argument in favor of such a method of supporting the roof over a roadway. I have seen accidents happen when a car knocked out a few temporary timbers set for the support of a bad piece of top. In one instance, the timbers were set by the instructions of the foreman, who was responsible for the results that followed.

In mine timbering, "Safety First" should be the watchword. Any person, whatever his position, should report any dangers that he may observe, and the foreman, or one of his assistants, should take prompt measures to remove the danger. Owing to the larger number of accidents occurring at the working face, more attention should be paid to visiting and inspecting the places where the men are at work, than in patroling the haulage roads and travelingways in a mine.

Duty of Miners to Insure Their Own Safety

Every miner's first duty, on entering his place in the morning and before proceeding to work, is to examine his roof carefully and reset any timbers that may have been discharged by a blast the night before. The safety of each miner depends on his taking this precaution. At a mine I visited not long ago, I saw a good sign on the headframe that read as follows: "Sound your roof. Set your posts. Load your coal. Safety first."

Safety in the rooms requires the prompt delivery of timber at the working face. When a miner finds that his timber has not been delivered, as ordered, it is well for him to stay out of his place until he can get the timber he needs. The loss of a dollar or so is as nothing compared with the danger of being hurt or killed by falling roof. I believe in systematic timbering, and a good rule to adopt at the working face is to set all timbers not more than 4 ft. apart or closer, if necessary. Even then, the safety of each miner depends on his keeping a careful watch of the roof in his place throughout the day.

It is well for a miner to remember that no good superintendent or foreman will excuse the driver who neglects to deliver timber promptly where it is needed in the mine. Most coal-producing states have certain provisions, in their mining laws, regulating the supply and the setting of timbers in mines, and these laws should be strictly obeyed. INSPECTOR.

———, Ind.

Longwall Work in Low Seams

Letter No. 2—In reference to the modified longwall system proposed by Charles Martin, *Coal Age*, Mar. 20, p. 520, I beg to submit the following outline bearing on the probable success of the method he has suggested:

In applying the longwall system to work a low seam of coal varying, say from 20 to 24 in., it is practically impossible to mine such coal at a profit, unless it is first undercut by a small longwall machine and loaded out either by means of a scoop or by the Thompson conveyor mentioned by Mr. Bain in his letter, *Coal Age* May 22, p. 965. I am not familiar with that conveyor but, from Mr. Bain's description, I should think that it would work satisfactorily, although it seems to me that the coal would have to be shoveled into the pans and then, of course, transported by means of rope haulage to the car on the main haulage road.

The scoop system, however, appears to be a great improvement on the Thompson conveyor, in that practically no shoveling need be done. It is astonishing how little coal this scoop will push to one side when it is drawn up from the haulage road to the end of the cut. In coming down again, the scoop fills itself and carries the coal to the chute where it is dumped directly into the car. It is also surprising to note with what ease this scoop will operate on a fairly uneven bottom; but, of course, the smoother the bottom the better the operation. The scoop is operated by a main and tail rope winding on a double drum, which is operated either by an electric or an air hoist. A complete description of this operation has been given in a recent issue of *Coal Age*.

In sections where there is locomotive transportation, direct current is available for the operation of the scoop hoist and also for the longwall undercutter. However, a longwall undercutter operated by an alternating-current motor has been perfected and gives excellent results, so that where direct current is not available, the hoist and undercutter can be operated by alternating current.

It is possible, of course, to drill the coal face by means of jackhammers and blow the coal off the solid, but this produces a lot of fine coal and makes an uneven face that cannot well be cleaned up by the scoop. In this system of longwall mining it is best to keep the face straight and at right angles to the main haulage road.

Length and Arrangement of a Longwall Face

I do not regard with favor Mr. Martin's oblique face, as it seems to me that it would cause difficulty in the operation of the mining machines. However, not having seen the operation of this oblique longwall face, I would not care to say that it does not have the advantages claimed.

It is my experience that a face of 300 ft., in bituminous mining, and 200 to 250 ft., in anthracite mining, is the best economic limit. To control a fracture it is necessary to have a man on the job who thoroughly understands the longwall system and will timber systematically, and make his rockpacks correctly.

Where the scraper system is used (and this applies as well to the Thompson conveyor) there is no trouble in moving the mining machine anywhere along the face, as the ropes can be detached from the scoop and attached to the machine, which is then moved by means of the hoist. In this way, it is possible to operate a longwall system on the fairly heavy pitches found in some of the anthracite mines.

There are many conditions that affect the operation of longwall work and which are not mentioned in Mr. Martin's article. For example, he does not say whether the section is dry or wet, or state the thickness of cover, presence of gas, character of the coal, kind of roof immediately overlying the coal and the presence of dirt or rock seams in the coal. Some of these would absolutely prohibit longwall work in this thin seam.

In answer to Mr. Martin, I can only make the general notes given above, but will say that where the coal is thin and conditions are favorable for any type of longwall mining, the combination of undercutting and scoop loading will produce coal as cheaply as any other method that I know.

In very many of the thin seams of the anthracite field, there is about a foot of rock above the coal and that comes down or is easily broken down after the coal is taken out. This makes an extremely favorable condi-

tion for building rockpacks. Moreover, the rock has a cubic fracture, which makes the building of uniform packs very easy.

All timber and cogs should be drawn so that the roof will come down and exert a uniform pressure on the coal face. Where the loading is done by scoop the cutting should, of course, be done on the nightshift, so that there will be no delay on the day shift when the coal is loaded out. It is unnecessary to add that the work should progress uniformly, as the success of all longwall work depends on this one fact.

Scranton, Penn. SUPERINTENDENT.

Available Oxygen

Letter No. 1—Reading the interesting reply to the question of a student who asked for the reason why a safety lamp will burn in the air but is extinguished in carbon dioxide, *Coal Age*, May 8, p. 880, tempts me to offer a few comments on the nature of blackdamp, which has been so fully investigated by the eminent chemist, Dr. J. S. Haldane, as well as by our own chemists of the Federal Bureau of Mines. In Miner's Circular No. 14, p. 13, it is stated that "average blackdamp contains 10 to 15 per cent. carbon dioxide and 85 to 90 per cent. nitrogen; the proportion of carbon dioxide is seldom more than 20 per cent. or less than 5 per cent."

The analyses made of mine air, of which the Bureau of Mines have made a large number, reveal the truth of the fact as claimed by Doctor Haldane that the dimming and final extinction of the lamp in blackdamp, in the mine, is chiefly the result of the depletion of the oxygen of the mine air, or in other words, the lack of available oxygen in the blackdamp, rather than to the presence of carbon dioxide. As stated in the reply to the inquiry on page 880, the burning of the lamp depends on the amount of available oxygen present, and where this is insufficient to support the combustion of the carbonaceous matter, the flame is extinguished.

Toxic Effect of Carbon Dioxide

While the experiments of the Bureau of Mines have established the fact quite conclusively that the extinction of the lamp in a mine atmosphere is not ordinarily due to the presence of carbon dioxide in the air but rather to the lack of oxygen necessary to support the combustion of the lamp, it is nevertheless believed that the presence of the carbon dioxide in such an atmosphere is the probable cause of the discomfort and distress felt by men compelled to breathe the air.

The experiments of Professor Clowes, in England, as well as those of the Federal Bureau of Mines, have shown that a mine atmosphere in which the oxygen has been depleted to about 17 per cent., by the addition of carbon dioxide generated in the mine, extinguishes the flame of a lamp burning sperm, cottonseed or lard oil *(Mine Gases and Explosions—Beard, p. 140)*.

The gradual depletion of the oxygen of pure air from 20.9 per cent. is accompanied with an increasing dimness of the lamp, until its final extinction at about 17 per cent. The acetylene or carbide lamp, however, continues to burn, according to the statement of the Bureau of Mines, until the depletion of the oxygen has reached 13 or 12 per cent. It is for this reason that objection has been made, at different times, to the use of the carbide lamp, which thus continues to burn in an atmosphere fatal to life. However, it seems to me that the labored breathing of a man in an atmosphere that is increasingly dangerous should be sufficient warning for him to withdraw to better air.

Again quoting from Miner's Circular No. 14, pp. 14, 15, in reference to the effect of breathing mine air low in oxygen, the following statement appears:

"Many authors have stated that mine air containing less oxygen and more carbon dioxide than ordinary outside air is in itself without effect on man. As regards oxygen, this is proved by the fact that in one pound of the air at a place 5000 ft. above sea level, like Denver, there is the same weight of oxygen as in one pound of air at sea level containing by volume 17.5 per cent. oxygen.[1]" This is followed by a quotation from Haldane that appeared to support the contention of such authors; but the Bureau of Mines draws attention to the fact that the statement of Doctor Haldane refers only to fresh air and has no reference to air containing carbon dioxide.

I thought these references would be of interest in connection with the question of available oxygen in the atmosphere. CHEMIST.

Scranton, Penn.

Certification and Safety

Letter No. 7—The question of the certification of mine officials, in its relation to the safety of mines and the men employed therein, I consider a very important and vital one not only to mine workers but to the coal operators who employ them and to mining men in general.

The matter of certification, indeed, involves not only the safety of the mine but the economy of its operation. In a brief manner, allow me to outline different types of men who, as candidates for mine foremanship, possess quite different degrees of ability in respect to safety and efficiency in the operation of a mine.

First, there is the man who is versed in mathematics, geology, ventilation, etc.; in other words, he has a good knowledge of the theory of mining. I will assume, however, this man has little practical experience that would enable him to produce a good tonnage of coal at a moderate cost of operation. His ability to handle men in a productive capacity is naturally quite limited; and, owing to his lack of mining experience, he is unable to put into practice his knowledge of the theory of ventilation, hauling, timbering, pumping and draining, methods of working and other things that the successful mine foreman must understand in a practical way.

Every cause has its effect and the capabilities of a mine foreman are the causes that must produce their effects on the daily production of a mine and the monthly cost-sheet, on which most largely depends the dividends that the owner of the mine or the stockholders have a right to expect.

Second, there is the practical mining man who has had a long experience in producing coal and handling men. Here, again, I will assume that this man lacks the knowledge of the theory of mining, which is his great

[1]This statement is wrong. The meaning intended to be conveyed is that, volume for volume, pure fresh air at Denver, containing 20.9 per cent. oxygen, holds the same weight of oxygen as air at sea level, in which the oxygen has been depleted to 17.5 per cent. In other words, breathing into the lungs the same volume of Denver fresh air (20.9% O.) and air at sea level lower in oxygen (17.5% O.) supplies to the lungs the same weight of oxygen each breath taken. However, breathing the rarefied air of Denver results in more rapid but not as deep inhalations as at sea level.

setback and the one cause that produces a most notable effect both on the regular daily production of the mine and the monthly cost-sheet. It is frequently necessary for this man to explain to the management why a day's tonnage has fallen short of the average, or why the cost-sheet for any month is unusually large.

Typewritten reports coming from the office inform our practical friend of the high cost of production; but these are matters that he cannot follow out in detail. The reports show that there are leaks somewhere but do not tell him where to find them, and he is at a loss to figure it out for himself. The superintendent to whom he goes in his dilemma is helpless to assist him, owing to a lack of practical experience. The results obtained by this foreman can be readily imagined.

Third, there is a candidate for foremanship who has both the technical knowledge and the practical experience required to make a successful man to place in charge of a mine. This man's failure, however, consists in his temperament. He is quick and impulsive and makes many mistakes on that account. For the same reason, he does not succeed well in the handling of his men. These are some of the causes that have their effect in lowering the tonnage and increasing the cost of production of coal.

Type of Foreman Mine Operators Desire

Fourth and finally, there is the really successful candidate for the position of mine foreman who possesses not only a full knowledge of the theory of mining, backed by a long practical experience in the operation of mines and the handling of men, but he has an even temper, good judgment and a manner that invites cooperation and gains the confidence of his men. They learn to trust him for a fair deal. He is a good judge of human nature and his knowledge of work enables him to tell what each man can do to the best advantage. The result of these characteristics in a foreman are far-reaching in securing a good daily tonnage and reducing the cost of production in the mine. He is the type of man that operators, generally, are seeking today.

Now, having before me these several types of men applying for mine foremanship, it is my conviction that coal mining is made safer and a higher efficiency will be attained by requiring the examination and certification of all candidates for the position of mine foreman, assistant foreman and fireboss. Indeed I would not stop here, but would advocate the examination of candidates for the position of mine superintendent and would suggest that a higher percentage of efficiency should be required for that position than for any of the others previously mentioned. Considering the matter from its face value, there appears to be no reason why a candidate for the superintendency of a mine should not be required to pass an examination that would determine his competency to hold that position.

A mine superintendent should naturally possess a full knowledge of all mining work, to enable him to counsel, advise and instruct the under-officials in his charge. Every year the work of coal mining is developing a greater need of technical knowledge in all mine officials, in order to produce a larger tonnage at a reduced cost of operation. We are, as it were, in a reconstructive era following the war. Let us look at our industrial problem from that viewpoint.

Allow me to say in closing that examining boards should be comprised of men of integrity and ability, who are fully acquainted with the theory and practice of coal mining and able, themselves, to answer the questions they submit to candidates. Not only that, but examiners must be able to judge, in a competent way, the answers submitted by men taking the examination.

JOHN E. AMBROSE.

Fairmont, W. Va.

Firebosses as State Officials

Letter No. 5—After reading the several letters written on this subject, I feel with Edward H. Coxe, that the employment of firebosses by the state would not work well. In his letter, *Coal Age*, May 8, p. 876, Mr. Coxe expresses the idea that state mine inspectors are employed to see that the mines are kept in a safe and healthy condition, and I would add that the mine foreman and his assistants are charged with the duties of looking after the safety and welfare of all the men employed underground.

The mining law of Pennsylvania and those of other states specify the duties of the foreman and his assistants, as well as those of the fireboss, who must examine the mine and report any dangers that he may find. It is my idea that the work of the fireboss is such that he should be subject to the mine foreman, who is in direct charge of the mines and responsible for its safe condition. These officials should work in harmony. If there is any reason why the fireboss should be employed by the state, there is all the more reason that the state should also employ the mine foreman and his assistants.

It has been suggested that state mine inspectors have too much to look after to make the necessary frequent visits to a mine to insure its safety. If that is the case, let me say that the state should employ more inspectors and give to each inspector a smaller district, or else deputy mine inspectors should be appointed to assist the district inspectors.

Disadvantage of Employing State Firebosses

In my opinion, the fireboss is the most useful person employed in a mine. His work is of such a nature that he is fully acquainted with every place in his district and knows each man that works there. For that reason, he can always supply much needed information to the foreman and, in many other ways, help to make a good day's run. How different would this be if firebosses were employed by the state?

Suppose, for instance, that a state fireboss, on duty in a remote section of a mine, finds that a wreck has just occurred on the haulage road and no coal can be hauled from that section until the track is cleared. Now, if this fireboss was employed by the company he would naturally feel an interest in the work of clearing away the wreck and getting out the coal. The foreman being away in another portion of the mine, he would throw off his coat and assist to clear the track. But on the other hand, a state-employed fireboss would naturally feel that the wreck was none of his affair and lend no assistance to get things again in shape. In other words, he would "pass by on the other side," with a lofty and disinterested air.

Other instances could be mentioned in which a fireboss employed by the state would prove a hindrance to the work of getting out the coal, instead of a help. Neither would the safety of the mine be made any more certain by state employment than where a con-

scientious fireboss is employed by the company operating the mine.

If it is true, as has been stated, that a mine foreman is disposed to underestimate the work of the fireboss and, as we say attempt to "put something over on him," the matter should be reported promptly to the superintendent, who ought to be broad-minded enough to straighten out the difficulty promptly, and do justice to a fireboss who performs his duties faithfully.

Where a fireboss receives just treatment, I do not think he would desire to be employed by the state. Moreover, every mine foreman should have qualified for his position, by serving a certain length of time as a fireboss and such a foreman will not generally be disposed to ill treat his firebosses, realizing as he will from his own experience the difficulties of that position.

McIntyre, Penn. THOMAS HOGARTH.

Letter No. 6—I want to endorse what Edward H. Coxe has said in his letter, *Coal Age*, May 8, p. 876. In his argument against the employment of firebosses by the state, it seems to me that Mr. Coxe has covered the ground so completely that there is little room for further comment on that side of the question. However, a few thoughts have come to me that I wish to present.

In the first place, whenever a mine is generating firedamp it is of the utmost importance to employ a thoroughly competent and reliable fireboss whose judgment in regard to conditions that are safe or unsafe will always be respected by both the mine officials and the men who work in the mine. Such a man will perform his duty equally well regardless of whether he is is employed by a company or the state.

DANGEROUS SITUATION CAUSED BY AN INCOMPETENT FIREBOSS EMPLOYED BY THE STATE

When a fireboss employed by the state proves to be incompetent or negligent in the performance of his duties, and the lives of men working in the mine are endangered by reason of that fact, neither the superintendent nor the foreman would have any authority to remove him from the mine. An application for the removal of a state fireboss would have to be made to the state appointing power, and that would require time. Before any action could be secured or relief obtained, a serious accident might result from that official's incompetence or negligence and the state would be responsible for the consequences.

Again, although this should not be, it must be admitted that there is always more or less of politics influencing state appointments, and I take it that the state employment of firebosses would not be immune in this respect. Nine times out of ten, the applicant with the "strongest pull" would secure the appointment, regardless of his relative competency and efficiency. No one will deny that this would seriously lower the standard of firebosses in our mines.

In discussing the efficiency of firebosses, a short time ago, Fred Turner stated that he knew of "firebosses who would do anything they are told, without regard to whether their acts are lawful or dangerous to the men working in the mine." In my opinion, such a fireboss would prove no safer in the employment of the state than if employed by a company, and his certificate should be revoked at once and the man sent back to the pick. Mention has been made of the awkwardness of a fireboss who is compelled to work under an inefficient foreman; but it appears to me that it would be a far more awkward situation for a company to be compelled to operate its mines under dangerous conditions, with an inefficient fireboss employed by the state and over whom they have no control.

In this state the mining law declares that the mine foreman and the gasboss, in the discharge of their duties, act as the representatives or agents of the operators or owners of the mine in which they are employed. The duties and responsibilities of both of these officials are the same as far as the safety of the employees is concerned. Although employed by the company, both of these officials act under the state law and are held responsible by it for negligence on their part. Now, it appears to me that if firebosses are to be made more efficient in the employment of the state, the same rule would apply to mine foremen and superintendents. It is my belief, however, that no greater efficiency will be secured and our mines would not be made safer by the state employment of mine officials; but there would result, instead, much confusion and delay in the important work of firebossing. JOHN ROSE.

Dayton, Tenn. Former District Mine Inspector.

Exhaust from Steam Pump

Letter No. 10—Referring to the letter of R. J. Pickett, *Coal Age*, May 22, p. 964, and the editorial note that follows the letter, I would like to ask the reason for assuming that Mr. Pickett's plan has for "its chief object the cooling of the water in the sump." The scheme is not clear to me although a sketch showing the exact arrangement would have made it a little easier to understand.

Mr. Pickett clearly states that exhausting the steam into the sump made the water very hot. What I fail to understand is that if it was possible to pump the hot water out of the sump, why should he attempt to devise a plan for cooling the water in the sump?

Now, according to the best information I have, a pump will not lift hot water, because of the vapor formed in the suction pipe destroying the vacuum required to raise the water to the pump. In the present case, the sump is said to be just below the pump and the lift was not therefore great.

It occurs to me that if this pump could be placed below the level of the water in the sump, so that the water would gravitate to the pump, such an arrangement would overcome the difficulty of handling the hot water and avoid the necessity of providing a means to cool the water in the sump. GEORGE J. KEARNEY.

Kincaid, Ill.

[It is true that a pump will not work with the same efficiency when the water in the sump becomes heated by the exhaust steam turned into the sump. However, this correspondent misjudges the case by suggesting that it is possible to continue pumping the water, which is growing hotter all the time. The plan devised by Mr. Pickett has for its purpose the cooling of the sump water, from time to time, by allowing water from the main to flow back into the sump. By this means, the temperature of the sump water is kept low enough not to seriously interfere with the pumping, the suction lift being very small.

This letter will close the discussion of "Exhaust from Steam Pump."—EDITOR.]

INQUIRIES OF GENERAL INTEREST

ANSWERED BY JAMES T. BEARD

World's Production Record

In the issue of *Coal Age*, May 1, p. 799, there appeared an article showing the effect of equipping a mine with self-dumping cages to increase its capacity, and mention is there made of a record hoist. This has since been referred to as a .'world record" by a correspondent, June 5, p. 1053.

In the first article, it is stated that the Orient mine, of the Chicago, Wilmington & Franklin Co., Mar. 6, 1919, hoisted 6777 tons of coal from a depth of 600 ft., which I agree must be a new world's record for a shaft mine hoisting one car of coal at a time.

It would be interesting to know two items regarding this hoist that are not mentioned in the article; namely, the number of hoists that were required to produce this tonnage and the number of hours in which the work of hoisting was performed. If *Coal Age* can supply this information, it will prove interesting to very many of its readers. G. E. HUTTLE.

Scottdale, Penn.

In response to our letter of inquiry, T. F. Holmes, general superintendent of the Chicago, Wilmington & Franklin Coal Co., at Orient, Ill., writes as follows:

"Regarding the record hoist made at the Orient mine in Franklin County and in compliance with your request, I am pleased to give you the desired data as taken from our reports: The Orient mine is 520 ft. deep. To this depth must be added 80 ft., the height of the dump circles above the surface of the ground at the lower landing, which makes the total height of hoist 600 ft.

"On Mar. 5, 1919, this mine produced 6422 tons of coal, making 1401 dumps in an 8-hour shift, notwithstanding there was a loss of 25 min. in the last hour, owing to valve-stem trouble on the hoisting engine. This accident prevented a record run being made on that day.

"On the following day, Mar. 6, the mine produced 6776.75 tons of coal, making 1502 dumps in an 8-hour shift in which only 8 min. were lost, 4 min. on re-dumps and shaker delays and 4 min. waiting on coal on the bottom.

"The average steam pressure on each of these days was 120 lb. gage. It may be of interest to add the following, which is the record of the number of hoists made in each consecutive hour throughout the day:

1st hour	195 hoists	5th hour	192 hoists
2d hour	190 hoists	6th hour	170 hoists
3d hour	188 hoists	7th hour	185 hoists
4th hour	192 hoists	8th hour	190 hoists

This is certainly a good record, even for a self dumping equipment in the shaft, and *Coal Age* will be pleased to learn of any record that will equal or surpass the one given. Such records show, not only the efficiency of the equipment, but indicate an equal efficiency in the mining and handling of the coal underground, including the work of gathering the cars at the working face, and hauling them to the shaft bottom.

The vast improvement made in the past ten and twenty years, in the management and operation of coal mines in Illinois, has established a record of which the state may well be proud and one that other coal-producing states could do well to follow. It is the result of the uptodate equipment of all the larger mines.

Errors in Surveying Practice

Kindly state, in the columns of *Coal Age*, what are some of the more common errors made by beginners in the work of surveying. I have been told that few engineers can measure off a distance of 1000 ft. and be sure of reaching the same point twice in succession. While this seems to me to be an exaggerated statement, I have found my own measurements to vary as much as 2 in. in that distance, although exercising my usual care in the performing work. SURVEYOR.

Des Moines, Iowa.

It is true that the measurements made by different engineers pulling a chain or tape over the same course will often vary surprisingly. There are a number of reasons for this: In the first place, all engineers do not exercise the same care in taking their measurements. Again, many engineers but more commonly surveyors do not realize the changes that occur in the length of a chain or a steel tape used in making the measurements and which may be caused either by the temperature of the steel or the pulling or tension exerted by the chainmen.

Of course, it is absolutely necessary to use a good steel tape when taking accurate measurements. Such a tape is usually graduated for a pull, of 10 lb. and care should be taken to approximate this pull when measuring. Again, when a steel tape is first run out, its temperature may be about 60 deg. F. In a hot sun, it requires but a short time for the temperature of a tape lying on the hot ground to increase a possible hundred degrees. I have known the tape to become so hot that it could not be held with comfort in the hand.

Now, taking the coefficient of linear expansion of steel as 0.000625, per 100 deg. F., a rise in temperature of 100 deg. would lengthen a 100-ft. tape $12(100 \times 0.000625) = \frac{3}{4}$ in. The lengthening of the tape this amount in 100 ft. would make the distance measured between two points 1000 ft. apart only 999 ft. $4\frac{1}{2}$ in., showing an error or difference in the two measurements of $7\frac{1}{2}$ in. This is one of the most common sources of error appearing when taking measurements over the same ground, in the summer and the winter seasons.

Another common source of error is caused by pulling too hard or not hard enough. A pull of 10 lb. on a 100-ft. steel tape, $\frac{1}{8}$ in. wide and $\frac{1}{50}$ in. thick, commonly used in surveying, will stretch the tape $\frac{1}{8}$ in. This is an interesting subject and there are many other errors to which we hope attention will be called by our readers who are interested in surveying.

EXAMINATION QUESTIONS

ANSWERED BY JAMES T. BEARD

Bituminous (Penn.) Firebosses' Examination, Apr. 11, 1919

(*Selected Questions*)

Ques.—Give the legal qualifications and state what other qualifications one should possess to properly perform the duties of fireboss.

Ans.—The Bituminous Mine Law of Pennsylvania (1911) requires a person seeking the position of fireboss, to hold a fireboss' certificate granted him by the examining board of the state, after he has successfully passed the examination given by the board. The law also requires that an applicant for a fireboss certificate must be a citizen of the United States, at least 23 years of age, of good moral character and known temperate habits. He must have had at least five years' practical experience after 16 years of age, as a miner or performing general work in the mine. He must also have had experience in mines generating explosive gas in Pennsylvania. Each applicant for a certificate must be able to read and write the English language intelligently and must furnish the board with a certificate testifying to his character and temperate habits and showing the length of his service in different mines. The law further requires the candidate to satisfy the board of examiners that he is able to perform the duties of a fireboss in gaseous mines. Besides receiving an average of at least 65 per cent. in the written examination, the candidate must undergo an oral examination in the presence of explosive gas.

In addition to the legal requirements just mentioned, a candidate for a fireboss certificate should have no physical ailment that will hinder him in the performance of his duties in the mine. He must be strong, have good hearing and eyesight, be conscientious and faithful in the performance of his work, honest in all his dealings with the company and with the men employed in the mine and possess the skill and courage required of a fireboss in the mine. He must also have a thorough acquaintance with and knowledge of the construction and use of the safety lamp.

Ques.—Name the various kinds of sign boards and danger signals authorized for use around the mine. State their special uses.

Ans.—There are danger signals and signs or warning boards to prevent men from entering places where danger exists, without due warning of its presence. There are also signs indicating the direction to be taken to reach the shaft bottom or mine entrance. Danger signals would seem to refer to any agreed signal transmitted into the mine and warning the men of impending danger. Such signals may be transmitted by telephone, signal bells or gongs, or by whistles blown at the surface by the hoisting engineer in charge at the time.

Danger signs or warning boards are of various kinds. They may be painted in bright red or the word "Danger" may appear in plain letters that can be easily read. In any case, such a sign warns men of their proximity to danger and is a reminder that they must not violate the mine regulations and rules. Firebosses frequently use a board or rail laid across the track, at the entrance of a room or near the face of a heading, as a warning to men to proceed no further toward the face. Such a board or rail may be marked with chalk to indicate danger. Chalk is also used by the fireboss, foreman, or assistant foreman to indicate a loose piece of top that is to be taken down and men are thus warned not to go under roof so marked. Signs indicating the direction to be taken in going out of the mine usually have the form of an arrow or are marked with an arrow pointing in the direction to be taken.

Ques.—Name at least four approved safety lamps and state what is meant by an approved safety lamp.

Ans.—One of the first lamps approved by the Federal Bureau of Mines was the Koehler lamp, both the steel and the aluminum type, then manufactured at Marlboro, Mass., and equipped with a "Macbeth, No. 2100, high-speed" glass and a pyro internal igniter, 1915 model. The Bureau of Mines next approved the Ackroyd and Best lamp, equipped with "ACK Best, A-1" glass and the Ackroyd and Best underground electric relighter. The Department of Mines at Harrisburg, Penn., has approved for use in that state, besides the two lamps just mentioned, the ordinary Clanny, the Davis deputy lamp, Wolf lamp, and a few others.

The term "approved safety lamp" refers to any lamp that has been examined, tested and approved, for use in mines, by a state or the Federal Government. Lamps approved by a state Government are approved for use in that state only, and the authorization does not apply to any other state. Authorization by the Federal Government is simply a gratuitous act on the part of the Government through the Federal Bureau of Mines, with a view to increasing the safety of mining operations. Such approval by the Federal Government does not prevent the use of other lamps in any coal-mining district or state. The matter of restricting the use of lamps in mines, in any state, can only be authorized through a properly constituted state board or mine official of that state.

Ques.—What observations would you make relative to the timbering of working places?

Ans.—Observe, first, that no coal is being loaded when one or more props have been knocked out by a blast and not been reset; and, second, see that sufficient timber of the right size is on hand in each place, and that all posts are stood properly according to the regulations of the mine, and the coal properly spragged.

Correction

Attention has been called to an error that occurred in the answer to the second question on page 970 of the issue, May 22, which should read $150 \div 0.9965 = 150{,}526$ cu.ft. This makes the gas generated in 24 hr., $24 \times 60\ (150{,}526 - 150{,}000) = 757{,}440$ cu.ft.

FOREIGN MARKETS AND EXPORT NEWS

EDITED BY ALEX MOSS

Diminishing Demand for Import Coal in Venezuela

Importations of coal to Venezuela have never been of very great importance. The figures for 1916 were: From the United States, 8507 tons; from Curacao (coal of American origin), 2031 tons; and from Great Britain 10,114 tons; total imports from all sources being 19,600 tons. In 1917 a total of 16,000 tons were imported, of which 8129 tons were from Curacao, 2039 tons from the United States and 6075 tons from Great Britain.

The importations of coal from England consist of Cardiff Crown briquets. These are ground coal compressed with some binding material into cubes of about 10 in. They can be stacked and counted and for this reason meet a demand that ordinary loose coal or small briquets can not fill, no matter how good in quality. In Caracas they have sold as high as $55 per ton. Formerly the railroads used them exclusively because they could be stacked upon the running boards of locomotives, thus avoiding the necessity of pulling a tender.

But the demand for these as well as for other sorts of imported coal is diminishing. The railways and the coastwise steamers are now using oil fuel, and some concerns having been forced to use Venezuelan coal, have found it better than they had thought. No bunkering is done in Venezuelan ports, that business in these waters being monopolized by the neighboring islands of Curacao and Trinidad, where labor is cheaper. The Venezuelan government operates coal mines near Barcelona and near Coro. Production appears to be stationary at about 20,000 tons per annum. A large deposit of coal near Maracaibo is being developed by an American company, and there is a prospect that Venezuela may be a large exporter of coal within a few years.

German Coal Trade

The subjoined information has been extracted from recent issues of the German newspapers by the *Iron and Coal Trades Review:*

The Minister for Economy, who refused to sanction the large price increases which the Westphalian Coal Syndicate decided to introduce Apr. 1, and who subsequently fixed maximum prices in the sense that the quotations which prevailed down to Mar. 31 were to be regarded as the maximum rates, has now been convinced by the Syndicate of the necessity for the particular increases which were proposed, and has sanctioned them with retroactive force as from May 1, subject to one condition. As now approved, the increase for coal is 20 marks per ton, including the coal and turnover taxes, with the exception of nut coals which are raised by 22 marks, while coke is increased by 30 marks and broken coke by 36 marks. The condition is that one-half (10 marks) of the coal price advance is to be placed to an equalization fund, which will be allotted to the pits which are working under the most unfavorable conditions. This arrangement is the same as that which was recently reached in regard to the collieries in Upper Silesia, and is now also being introduced in Saxony.

One of the articles of the peace treaty stipulates that Germany has to deliver coal to France for ten years to the amount of the difference between the production of the mines in the Nord and Pas de Calais before the war and the annual output in the ten years in question. In addition, Germany grants the right to France to receive 7,000,000 tons of coal per annum for ten years, to Belgium to obtain 8,000,000 tons of coal in 1919-20, and rising to 8,500,000 tons in 1923-24, at prices which are fixed in the treaty. It is permissible for coke to be supplied in place of coal in the proportion of three tons of coke to four tons of coal. Provision is also made for the delivery of benzol, coal tar and sulphate of ammonia to France for three years. The commission is empowered to postpone or cancel these deliveries should they be inconsistent with the industrial requirements of Germany.

It is reported that the government is engaged upon plans for prohibiting strikes by the introduction of a system of compulsory arbitration, as in Australia and New Zealand.

Coal Output in Scotland in 1918

The coal output in Scotland last year was 36,121,424 tons, a decrease of 2,355,526 tons, compared with 1917. The number of persons employed was 124,477. Of this number, 96,558 were employed under ground, and 27,919 above ground. In 1917 the number employed in coal-mining operations was 130,027.

Carrying Coals to Newcastle

If newspaper reports emanating from London convey the truth, then American coal operators who find business dull on this side of the ocean have been sending emissaries to Wales to find a market for their surplus product. The rumor hath it that some American salesmen, taking advantage of the state of the Welsh coal market and the need of the Welsh operator, are offering to fill orders for producers who are not in position to execute contracts on time owing to the shortage of raw materials and labor.

These agents are offering the prospective British customer coal placed on board at Newport News at $6.10 a ton, which is about half the price Welsh mines can deliver coal f.o.b. at any of the Welsh ports. In addition they are guaranteeing to deliver this coal at certain dates, which the Welsh collieries are unable to do.

In the Swansea manufacturing region, which is the center of Welsh industry, merchants and other coal consumers are being approached by the representatives of American coal shippers with a proposition to take care of British orders that cannot be supplied through the usual channels. The suggestion is made that any orders that cannot be executed will be filled by America to mutual advantage.

British Coal Output

Sir Auckland Geddes recently announced in the House of Commons that the output of coal per person employed in or about the mines continues to show a decrease. In the face of this England will either have to reduce the supply of coal to industry and for domestic use, or to limit even more strictly than at present the amount permitted to be exported. According to figures published in *The Times* (London), the output for the first three months of the present year is as follows:

Four Weeks Ended	Number of Persons Employed	Output, Gross Tons	Output per Person, Gross Tons
Feb. 1.....	1,064,828	18,321,100	17.2
Mar. 1.....	1,097,541	19,472,200	17.7
Mar. 29....	1,106,299	18,676,200	16.2

On the basis of the figures the total production for 1919 would be about 224 million tons, as compared with 227,714,579 tons in 1918.

Discussing the question of Great Britain's coal supplies, the London *Times* remarks that it is extremely doubtful whether the great mass of the British people realize how serious is the position, even in the great industrial districts in the north. Manufacturers may expect to receive the same supplies as allotted to them up to the end of June, but after that a reduction of 12½ per cent is likely.

Holland in 1918 imported 1,259,144 metric tons only of coal and briquets, as against 2,661,390 tons in 1917 and 5,679,906 tons in 1916. On the other hand, she exported 113,757 tons of coal and briquets in 1918, as against 58,037 tons in 1917 and 82,158 tons in 1916.

Foreign Trade Summer Courses

Columbia University, New York City, has announced that it will give summer courses to those interested in foreign trade, as also will New York University. The course at Columbia University will be in charge of Prof. Guy Edward Snider and will consist of (1) Marketing Methods in Foreign Trade and (2) Economic Geography of International Trade. The course at New York University will cover (1) Foreign Trade Geography, (2) Methods in Foreign Trade, (3) Export Technique and (4) Foreign Exchange and Foreign Credits.

The Swedish State Railways and various gas works in Stockholm have bought 100,000 tons of American coal at prices somewhat lower than those at which English coal was offered.

Coal and Coke News

Harrisburg, Penn.

The bill requiring the delivery of explosives to miners (in the anthracite region) at points below the surface has been reported from committee, but with several amendments. The bill provides that on and after the first day of July, 1919, explosives to be used by the miners in the anthracite coal field shall be delivered to them by the operator of such mine or by his representative at a point below the surface most convenient to their place of work.

One of the amendments says that, "If any controversy shall arise between any miner, operator or foreman as to the points at which explosives are to be delivered, such controversy shall be referred to the proper mine inspector, whose decision thereon, taking into consideration practicability and safety, shall be final.

"Explosives shall be taken into the mines for the use of the miners and shall be there transported and stored under such rules and regulations as may be prescribed by the chief of the Department of Mines, and no greater quantity of explosives shall be taken into or held in any mine at any time than that necessary for delivery to the miners of such mine for one day's work."

Section two of the bill states that the quantity of explosives supplied each miner shall be in accordance with an order left by such miner at the mine foreman's office the day previous, the quantity not to exceed the amount provided by law.

The bill states further that any operator who shall fail, or neglect, or refuse to furnish explosives to miners as in this act provided, has committed a misdemeanor. An amendment has been added to this section which reads, "or who shall fail, or neglect, or refuse to furnish explosives to any miner as required by any decision of the mine inspector or who shall violate any of the rules and regulations adopted by the chief of the department under the authority of this act," shall upon conviction be sentenced to pay a fine of ten dollars for each such failure or neglect.

Lacking three votes of the necessary constitutional majority, the Flynn anti-sedition bill was defeated in the House on June 17. The vote was 101 to 84. Governor Sproul backed the measure and it was prepared by Attorney General Schaeffer. Though beaten in endeavoring to put the bill through, the proponents of anti-sedition legislation are jubilant at the showing made in the face of the stiffest possible opposition. There is hardly a doubt that the bill will go back on the calendar and enough votes be mustered to pass it by a substantial majority. Representative David Fowler, a national organizer for the United Mine Workers and floor leader for organized labor, led the battle against the measure, which he claimed was aimed directly at organized labor. Fowler's fight at times bordered on the sensational.

Nine men who were on the ill-fated trip of cars on the morning of the Baltimore No. 5 tunnel disaster, recovered from their injuries and recently discharged from the hospitals, were given a hearing on June 17 by the committee of investigation (six state mine inspectors) but no new light was thrown on the exact cause of the accident. All the men told of seeing the flash, followed by the fire, but were unable to say how the powder was ignited. The evidence shows that the causes have dwindled to smoking and electricity, but no definite testimony was received to prove that either of these caused the ignition of the powder. The pipe that was in the fatal car on the morning of the accident is the mute evidence that shows that some one was smoking.

Uniontown, Penn.

There have been three outstanding features in the industrial situation in the Fayette County or Connellsville coke region during the past week: (1) Demand for coke contracts from furnace interests. (2) Tightening up of the byproduct coal market. (3) Growing indications of an early labor shortage. Operators are giving quite serious attention to the labor situation which is expected to assume vital importance during the ensuing two months. A large number of workers, particularly Italians, have recently left for their native land and their absence will be felt materially with the return of normal conditions in the region. So far there has been no marked exodus of peoples of the Slav nations and in fact there is a strong movement on foot throughout the region to prevent these peoples from returning for some time, at least, in order to give the new republics, especially Czecho-Slovakia, an opportunity to get established firmly. It is pointed out that the difficulties there are such as to require the undivided efforts of the government with the population already there without being called upon to provide for the hundreds additional from the United States who are anxious to return and greet members of their families and relatives whom they have not seen or heard from since before the war.

While the inquiries for byproduct coal have been quite numerous during the week, no large contracts have been reported. The steam-coal situation is practically unchanged, plants which are in operation now working on a month to month basis. Expiration of June orders, however, probably will lead to a flurry during the last week of the month in placing orders for July business.

Demands for coke contracts are coming rapidly from furnace operations which are about to resume work. The favored plan just now is the placing of contracts on a sliding price range, with monthly revision, and upon a basis for coke of 5¼ or 6 to 1 as to pig iron. A few short-term contract deliveries are being made at around $3.50 to $3.90 while spot coke, quite scarce, is selling at around $4.00. During the week approximately 450 more ovens were placed in operation.

Charleston, W. Va.

If little or no headway is being made in increasing production in the various fields in the Charleston section, it is due not so much to general market conditions as to the inability of operations to secure enough cars. Such conditions have prevailed for about a month. For instance during the second week of June, mines were still unable to operate to capacity owing to car shortage but lately the supply has been somewhat better but still entirely inadequate to meet the demand. Added to the car scarcity is a shortage of miners tending to further curtail production; so that production in several fields of West Virginia was not over 75 per cent. and in some instances not that large, when in the face of a constantly increasing demand much more coal could and would have been mined. Conditions in the southern part of West Virginia reflect an even stronger market. There being, however, no sweeping advances, some kinds of coal even lagging behind in the procession. That was specially true as to ordinary steam coal, though the demand for it was better than had been true in earlier weeks. Mine-run is enjoying a better market while prepared sizes both in the smokeless fields and elsewhere are at a premium, in fact the output of a great many operations is sold as to prepared sizes. Pressure for coal from export sources is partly responsible for the increased demand, the movement of coal to tidewater during the week ended June 14 being especially heavy. An embargo in effect for a few days held down the lake tonnage, but with the rescinding of the embargo order coal again moved in large quantities to Lake ports. There appeared to be a much stronger demand for mine-run in western markets and that had its effect on slack coal which had been rather sluggish.

Under favorable transportation conditions the New River field would have been able to produce up to the capacity of its mines during the second week of June because market conditions for smokeless coal were conducive to a large output. However, the mines produced not more than 75 per cent. of the normal output. Export shipments were still growing in volume, though lack of vessels tended to hold down such shipments. Prepared sizes continue to advance and now approximate $5.00 a ton, it is stated, while mine-run is quoted at about $3.00 a ton and slack at from $2.35 to $2.75.

Production was greatly retarded in the Kanawha district, labor was scarce and it was not found possible to produce more than 60 per cent. of capacity. Much Kanawha coal was being shipped to tidewater. Prepared sizes were in prime demand and it was expected that a stronger market for mine-run would increase slack sales. The maximum price for prepared sizes was said to be $3.25, running from that down to $2.50 while the general average for mine-run, contract, was $2.25.

Fairmont, W. Va.

As an index to conditions in the Fairmont and other fields in the northern part of the state, on Saturday, June 14, shipments of coal from the Monongah division of the Baltimore & Ohio were larger (with one exception) than at any time during the present calendar year. The increase in shipments was most marked as to eastbound tonnage, more especially as to tidewater shipments and that means a steadily mounting export business. Much of the export business is being handled by the big companies who have the larger selling organizations, but some of the smaller companies are also participating. Only about 900 cars were loaded for Curtis Bay in four days, while the total loads of coal from Monongah division mines for the entire second week in June for all points reached a total of over 4800, it is estimated. Western shipments decreased in volume, the tonnage moving to Lake ports being below that of previous weeks. So far operators in northern West Virginia have not been troubled by a scarcity of cars or labor; fewer unconsigned loads were on hand. There was also a decrease in the number of idle mines and mines being operated were on a full-time basis. Run-of-mine (spot) was averaging over $2.00 while $2.50 and $2.60 per ton was an average price for prepared sizes. The price of slack ranged anywhere from $1.50 to $2.10, the average price being $1.75.

Huntington, W. Va.

There was an excellent attendance at the annual meeting of the West Virginia Coal Association held here on June 10. Aside from the election of officers for another year, the most absorbing question before the association was as to whether or not West Virginia operators favored a continuance of government supervision of the coal industry.

There was almost unanimous opposition to resuming the submission of monthly cost reports to the Federal Trade Commission, as such reports were not to be treated as confidential and, furthermore, it was considered that the submission of such reports was a phase of government control.

The executive committee at a meeting held after the adjournment of the annual meeting re-elected J. G. Bradley, of Dundon, as president; E. Drennen, of Elkins, as vice-president; Walter H. Cunningham, of Huntington, as secretary; A. H. Land, of Huntington, as treasurer. Mr. Drennen was the only new officer elected, succeeding G. H. Caperton.

After brief discussion the eastern car pool matter was left in the hands of the association's executive committee.

Terre Haute, Ind.

The production of coal in the mines of Indiana during May amounted to 1,307,325 tons, a small increase over April, which was 1,245,921 tons. The increase, while relatively small, is held by many operators in the coal field to indicate at least a start of a revival of the demand for fuel, inasmuch as the market ordinarily takes less coal during May, June and July than in any other months. The tonnage reported for May was produced at 197 mines, as compared with 189 during April. Several mines in the state are still closed; practically all are working only part time. A loss in production resulting from car shortage was apparent for the first time in several months, the loss from this source amounting to 84,587 tons. It was estimated that the full time capacity of Indiana mines during May would have been 2,887,372 tons, but it is not probable that this maximum production will be attained any month this year. Distribution of railroad contracts among many mines, instead of their concentration in a few has had the effect of more evenly distributing the working time of the various properties and, consequently, has improved, in a measure, the general working conditions.

Ottawa, Ont.

The final report of C. A. Magrath, Canadian Fuel Controller, was presented to the House of Commons on June 2. It emphasizes the necessity of devising every possible economic method of developing Canadian fuel resources. It would greatly help to maintain a favorable balance of trade if every effort were made to conserve and utilize to its full value all fuel brought in, and at the same time to develop the coal-export business in the maritime provinces, British Columbia and the West. The attention of builders, municipalities and others is drawn to the greater efficiency and saving in the cost of fuel obtained by the use of central heating plants in closely-settled parts of cities in the United States. The recommendation is made that the government should discourage the use of electrical energy for heating houses as being wasteful, considering that where used as power it has ten times the efficiency. Other recommendations are that classes for furnacemen should be held in each municipality to teach the conserving of fuel; that furnace manufacturers should be canvassed to see if they can be induced to make furnaces suitable for burning soft coal; to secure better building inspection of air spaces between walls to obtain protection against cold; that mines should be inspected to see that there is no waste in the extraction of coal; also provision should be made so that the cost of coal is not increased by over-capitalization, and that the report should be submitted to the consideration of the Advisory Council for Scientific and Industrial Research.

The Hon. A. K. Maclean, Acting Minister of Trade and Commerce, has issued a statement on the Canadian coal situation. He draws the attention of the public to the fact that owing to lack of orders many mines were forced to close down in the early spring, with the result that some seven million tons of coal, or one-twelfth of the yearly output was lost to the trade; there is, in consequence, a shortage of just that amount of coal with which to enter next winter. Under these conditions there is only one sound policy for the Canadian consumer to follow, both in respect to imported and also as to domestic coal. That is to keep pressing for supplies and to leave nothing undone until each consumer has at least a substantial portion of his next winter's supply in his cellar. The public need not look at present for a reduction in coal prices, as if there is to be any change every indication points rather to an increase.

Montreal, Que.

The first meeting of the special committees appointed by the Dominion Steel Corporation and the Nova Scotia Steel and Coal Co., to consider the possibility of reaching an agreement for the redistribution of the submarine coal areas leased by the two companies, were held here recently. It is stated that the following represented the Dominion company: J. H. Plummer, formerly president of the Dominion Steel Corporation; Hector McInnis, a director of the company, and William MacMaster, of Montreal. The Nova Scotia Steel and Coal Co. were represented by the following: D. H. McDougall, president; Colonel Cantley, chairman of the board, and W. D. Ross, vice president. It is of interest, says the Wall Street Journal, that Mr. Plummer heads the Dominion company committee, for when he was president of this company he recognized the ultimate necessity of some rearrangement of the various properties operated by the two companies. Mr. McInnis had charge of the entire undertaking before the Legislature of the Province.

If the companies in question fail to reach an agreement, then the Provincial Legislature will intervene and settle the matter in a manner which it may consider to the interest of the province. Many believe that the present negotiations may lead up to a possible merger between the two companies involved.

Victoria, B. C.

Joseph Hudson, of the Explosives Branch, Department of Mines, Ottawa, is making a tour of Canada on business of considerable importance to the mining industry. At present he is in British Columbia and has interviewed Hon. William Sloan, Minister of Mines, and other officials in the Department of Mines. He announces that it is the intention of the Ottawa authorities to provide the finances necessary for the installation at the Canadian capital of a powder-testing plant modelled after that of Cumberland, England, and Pittsburgh, Penn. At the present time there is no provision in Canada for the official testing of explosives used in the mines of the country.

The Provincial Government had been authorizing the use of those explosives passed by the United States Government authorities or recognized and approved by the British Government. If necessity arose for the testing of a certain grade of powder, and the coal dust of the mines in which it was proposed to be used, then it was necessary to send samples either to Cumberland or to Pittsburgh. With a plant at Ottawa, not only would a uniform list of authorized explosives be adopted in Canada, but it would be possible for all such testing and experiments to be carried out within the Dominion.

If the proposed plans are carried out it is understood that manufacturers of explosives will be required to submit their output to test in the official laboratory; also plans of new plants will have to be submitted to the proper authorities for approval.

Another innovation suggested is that regulations regarding the sale of explosives shall be uniform throughout the Dominion. This will be a marked improvement over the present somewhat haphazard method. Mr. Hudson's mission, therefore, is to lay these various proposals before the heads of the Mines Departments in the different provinces, explain them in detail, obtain suggestions and generally come to a clear understanding of the objects aimed at; then when Dominion legislation is finally drafted, it should meet conditions in all parts of the Dominion and be unanimously approved.

PENNSYLVANIA

Anthracite

Lansford—The Lehigh Coal and Navigation Co. will build a number of new tenament houses during the summer. The G. B. Markle Co., of Hazleton is also improving and rebuilding all its mine villages, putting the houses in first-class condition.

Shenandoah—The Continental washery, which has been idle since Feb. 8, resumed operations recently. The washery is owned by the Lehigh Valley Coal Co., and is one of the many washeries that were erected during the war to relieve the coal shortage. It has a daily output of 1250 tons.

Ebervale—Anthracite miners continue to be in demand. The G. B. Markle Co. announced on June 9 that it was still short of practical hands and is scouring the entire region for men holding certificates to mine coal. Efforts are being made to induce former residents of the Lehigh section now working in other parts of the state to return to their old occupations.

Shamokin—To prevent a tying up of its collieries between here and Mount Carmel, the Susquehanna Collieries Co. has inaugurated an auto bus service to convey the miners to and from their work. Practically all big trucks in Shamokin and Mount Carmel have been hired to make morning and afternoon runs to the collieries, during the strike of the trolley men.

Philadelphia—The Monash line of pressure reducing valves and pump governors, formerly manufactured and sold by the Monash-Younker Co., of New York and Chicago, has been acquired by the Harrison Safety Boiler Works, of Philadelphia. The Harrison Safety Boiler Works will manufacture and market the valves under the trade name "Cochrane-Monash," and will supply repair parts for valves now in use.

Inkerman—The electric storm on June 15 created havoc at the Red Ash shaft of No. 14 colliery of the Pennsylvania Coal Co., doing considerable damage, and it is likely that the Empire tower, which stands about forty feet high will have to be dismantled and rebuilt. The shaft has been abandoned for several months. It is equipped with modern machinery and after being sunk to the Red Ash seam, a distance of about 550 feet, it was decided by the officials to postpone underground development for an indefinite period.

Hazleton—It is stated that traces of a mine fire that existed in the Honey Brook No. 3 workings over a score of years ago have been discovered in the strippings at this plant several miles south of this place. The Lehigh & Wilkes-Barre Coal Co. operates the property.

Coöperating with the Government authorities, the coal companies are canvassing their men in an effort to ascertain their ideas regarding citizenship in this country. The information is also used in the collection of income taxes. A surprisingly large number of aliens seem to have no desire to take out citizenship papers.

Bituminous

Waynesburg—Paul B. Dick of Connellsville, has purchased several hundred acres of coal in Wayne Township, Greene County, from various owners.

Brownsville—William F. Ellwood, Susan Ellwood Mounts and Agnes Ellwood Brownlee, all of Washington, and E. E. Morris, of Waynesburg, have sold to the Pittsburgh Coal Co. two tracts of coal, one tract in Amwell Township containing 15.8 acres and the other in Canton Township, containing 108 acres. The price paid per acre was $300.

Scottdale—Organized play is to be an innovation this summer at the Phillips plant of the H. C. Frick Coke Co. For years past every Frick plant has had a playground with a band but the equipment at Phillips is to make provision for worth-while games which will appeal to the workers and their wives as well as the children.

Pittsburgh—The Hecla Coal and Coke Co. has been granted a permit by the United States Government to construct a steel tipple with a concrete pier and trestle supports on the right bank of the Monongahela River, 3.5 miles above Lock No. 6 at Rice's Landing and 72 miles above the mouth of the river. This plant is at the Isabella mine and is to replace the river tipple carried away by the ice winter before last.

Meyersdale—H. M. Habeeb and S. Silomon, both of Windber, have purchased 375 acres of coal land at this place from Aaron Cober and Joseph Lint. The land is near Keystone Junction and is underlaid not only with good coal but with several strata of sandstone. The new owners contemplate the development of a modern mining plant and the erection of a crusher to manufacture sand for commercial purposes.

Brier Hill—Officials of the Brier Hill Coke Co. made a trip to Fayette County, from Youngstown, Ohio, in a special train for the annual election of officers and inspection of the Fayette County operations of the company. All officers were re-elected as follows: President, Thomas McCaffrey; vice president, W. H. Warren; secretary, W. B. Phelan; treasurer, N. B. Folsom; directors, Colonel J. G. Butler, Jr., Thomas McCaffrey, W. H. Warren, G. L. Alderduce, John N. Allen and W. B. Phelan.

Pittsburgh—A dinner was given on May 27, by Dr. A. A. Hamerschlag, president of Carnegie Institute of Technology, at which a number of prominent coal operators were present. Announcement of a new Carnegie mining engineering department of the Institute was made at this time. Coöperation between all interests involved is promised. The operators were highly in favor of this plan and resolved that the gathering give its moral and material support to the form of education proposed by which students may receive combined technical, practical and business training necessary to fit them for service in coal mining.

Scholarships are offered; each operator whose production averages 1000 tons a day is to give one scholarship each year to young miners or sons of miners who cannot otherwise obtain such schooling. This school is expected to start next fall and an advisory board has been selected on which are prominent coal men.

WEST VIRGINIA

Clarksburg—Though yeggs succeeded in demolishing the general store of the Elkhorn Fuel Co. at its Ocean mines near here on June 4, through using too much explosives on the safe they succeeded in carrying off only a small amount of loot.

New River—The Buffalo Coal Co., recently incorporated with a capital of $75,000 has leased about 1000 acres of coal in this section, and plans the commencement of development work at an early date. It is said that the daily capacity of the plant will be about 800 tons. A. B. Day, John F. Shea, and M. T. Devault, all of Knoxville, are the incorporators.

Beckley—The Winding Gulf Operators' Association at its meeting at White Sulphur Springs, W. Va., went on record in a series of resolutions as favoring any movement for the advancement of the physical and moral welfare of the miners, the strict enforcement of the prohibition laws, better educational facilities, better schools and higher salaries, also the establishment of mining schools at various operations.

Huntington—A syndicate of this place, composed of C. W. Jones, W. E. Minter, J. B. Purcell, A. J. King, C. P. Donovan, E. J. Payne, John Clapperton and S. J. Hyman, recently closed a deal with the Hutchinson Lumber Co. involving the transfer of 2500 acres of coal land in Fayette County. Two mines are now in operation on the tract and a third is being opened up by the Greenbrier Collieries Co., in which the Hutchinson company held a fourth interest.

Charleston—The Turkey Knob Coal Co. is seeking an injunction to restrain the state tax commissioner from collecting additional amounts which he claims are due from all corporations in the way of an excise tax owing to the increase by the legislature of the rate by one fourth of one per cent. The effort of the Turkey Knob company to secure the injunction is in effect a notice of an appeal from the decision of the State Board of Public Works which sustained the Tax Commissioner in his ruling that the increase applied to the state's fiscal year beginning July 1, 1918, and ending June 30, 1919. The Turkey Knob company applied to Judge Rummell, of the Kanawha Circuit Court for the injunction but he refused it and it is now the understanding here that the company both on its own behalf and on behalf of others will apply to the Supreme Court of the state for an injunction. In fact a chancery suit has already been filed in the Kanawha Circuit Court as to just what period of the year the increase applies. A quarter of a year's additional excise tax is due according to the Tax Commissioner.

KENTUCKY

Louisville—The W. E. Caldwell Co., of this place, tank manufacturers, will build a 30,000 to 35,000 cut band saw mill in St. Landry Parish, La., where the company owns large tracts of cypress, ash, oak and gum timber. J. B. Crawford, an experienced saw mill man is connected with the enterprise.

Lexington—The Kentucky Mining Institute recently elected officers as follows: H. M. Ernst, Sturgis, president; C. W. Strickland, Ashland, secretary-treasurer; vice presidents, Alex Frost, Wilton; J. P. Gorham, Lexington; J. H. Hall, Whitesburg; H. H. Small, Chicago; A. G. Spillman, Earlington; R. C. Thomas, Paintsville; H. H. Townsend, Athens, O.; Louis Frances, Crofton.

OHIO

Columbus—A new bill of lading which goes into effect on all railroads, Aug. 8, does not limit the liability of carriers to the cost of the coal at lading and also does not place responsibility for coal cargoes on the owner, when held by railroads as warehousemen. In other words where the coal is on track in storage which is paid for, the railroad company must assume all losses.

Martins Ferry—The Fred R. Jones Construction Co. of Chicago, which is constructing the sidetrack for the Pennsylvania railroad from the W. & L. E. to the new Youghiogheny & Ohio mines on Little Short Creek, Jefferson County, has taken the contract for loading the 30,000 tons of coal piled near the Bud mine. The company has been piling coal beside its Bud opening since the first of the year at the rate of 200 tons a day, as it was impossible to load on the railroad until the branch line was put in. The Jones company will use steam shovels to load the coal.

The construction company is expected to be at work all summer in completing the contract of laying the branch railroad on up the creek to the new Dorothy mine.

ILLINOIS

Hallidayboro—The Jackson Coal Co. is now installing a new 150 k.w. electric generator at its mine to take the place of the one formerly used, which was too small to supply the demand. New storage battery motors were recently put into use at this mine. The new generator will be driven by a corliss engine.

Chicago—A warning that America faces a possible coal shortage more serious than that of eighteen months ago was sounded recently by a special committee of the National Coal Association, whose membership produces approximately 75 per cent. of the country's bituminous coal.

The committee, headed by F. C. Peabody, of Chicago, pointed to the production decrease of 50,000,000 tons from January 1 to May 10, as compared with a year ago, declared there are grave dangers of a labor shortage, and urged that consumers place their orders now, and thus set the idle mines in full swing again.

Sesser—Final plans are now being completed for the sinking of a new mine near here on the Chicago, Burlington & Quincy R.R. The company which will prosecute the work was recently formed with a capital of $5,000,000. The members include several prominent business men of Sesser and also Jesse Diamond of Chicago, D. M. Parkhill of Benton and Thomas Horn of St. Louis, all of whom are interested in the Modern Coal Co. The Modern Coal Co. recently completed a new mine at Sesser which ranks among the most modern in southern Illinois. The mine which this new concern is now planning will also be large and well equipped.

Springfield—Coal mines in the Springfield district are working as follows: The Peabody No. 6, one of the large mines of Central Illinois, employing more than 500 men, is working steadily. The Girard and the Capitol mines are down, the Athens mine is working four and five days and the Spring Creek mine averages about five days a week. Other mines which are putting in good time are the New Citizens, with an average of four days a week, the Klondike, working an average of three or four days, the Woodside working four and five days, the Panther Creek, about two days and the Divernon and Auburn mines about four days a week. The Tuxhorn mine, which has been down, will open July 1.

Zeigler—This place promises to be one of the largest mining towns of southern Illinois. Another new mine has just been sunk near the old plant of Bell & Zoller. These mines are the only ones in the southern part of the state which are said to be working full time. Ample facilities, such as water, light and power are supplied by the large mines which are located close to the town. A new and modern hospital is maintained and the city is to have, in the near future, one of the best labor temples of this section. The local union of miners at Zeigler recently held a labor picnic and celebration at which there were about 5000 persons present. The speakers were: Frank Farrington, president of the United Mine Workers of America, Mother Jones and Edward Carbine, of the Illinois State Federation of Labor. A part of the celebration was in the form of a big parade; dinner was served at the city park.

ALABAMA

Birmingham—The Alabama Fuel and Iron Co. of this place has completed negotiations for the purchase of a tract of about 1640 acres of coal and is said to be planning for development. The new property is located in Harlan County, Ky. Charles F. De Bardeleben is vice president and general manager.

Alabama produced 19,521,840 net tons of coal and 4,344,726 tons of coke during 1918, according to figures compiled by Chief Mine Inspector C. H. Nesbitt for incorporation in his annual report. Compared with the record production for 1917 of both coal and coke, there was a decrease of 891,971 tons of coal and a shortage of 523,872 tons of coke. Jefferson County, producing over half the coal tonnage for the state in 1917 and 1918, fell below the 1917 record by 980,109 net tons.

MISSOURI

St. Louis—Shipments of coal into this city last year were 1,052,283 tons in excess of the preceding year and 4,933,700 in excess of 1915, according to the annual report of the Merchants' Exchange. The receipts of coal here were as follows: In 1918, 12,905,755 tons; in 1917, 11,853,472 tons; in 1916, 9,683,806 tons; in 1915, 7,972,055 tons. The receipts of anthracite, included in the report, were 64,515 tons in 1918, against 163,789 tons in 1917. The receipts of coke were 168,205 tons last year, against 217,236 tons in 1917. Of the receipts of anthracite, 48,436 tons were local and 16,079 through. The Illinois Central carried the greatest tonnage, 1,787,691; the Southern was next with 1,400,248; the Louisville & Nashville was third with 1,247,660 tons.

Personals

Arthur King Wood, formerly president of the Franklin Trust Co., has been elected vice president and treasurer of Westinghouse Church Kerr and Co., of 37 Wall St., New York City.

Herman T. Garrison has resigned his position with the Madison Coal Corporation at Carterville, Ill., to accept one with the Hartwell people who operate a new mine at Hartwell, Ill.

C. F. Bashore, formerly manager of the New England Fuel and Transportation Co., Grant Town, W. Va., has accepted a position as manager of an operation of the Randall Coal Co. along Scott's Run.

John Chisnell, mine foreman at No. 5 colliery of the G. B. Markle Co., was seriously injured by a runaway car recently. His assistant, Charles Tyson, also sustained a fractured leg in the same accident.

Harold M. Stagg, formerly New York sales manager for Weston Dodson & Co., Inc., has been appointed general manager of sales of the Pennsylvania Collieries, Inc., with offices at 500 Fifth Ave., New York City.

Charles Gottschalk has resigned his position as chief engineer for the Union Colliery Company, at Dowell, Ill., and has been succeeded by W. T. Detweiler, of St. Louis. Raymond J. Dowd, also of St. Louis, will be assistant engineer.

Robert H. Kann has been appointed superintendent of Mine No. 24 of the Consolidation Coal Co., having been superintendent at the No. 55 mine of the company. For the time being J. H. Nuzum will act as superintendent at Mine No. 55.

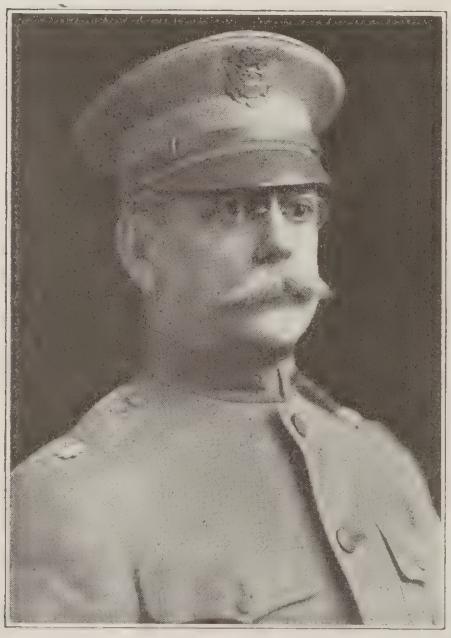
Col. William Leckie, head of a number of coal companies operating in the Pocahontas region has purchased the Kelley & Mayer Building in Bluefield, W. Va., and will use it as the headquarters of 10 different companies in which he is interested.

C. S. Coler, especially fitted by education and experience, was recently appointed manager of the educational department of the Westinghouse Electric and Manufacturing Co. He is also president of the Casino Technical Night School and chairman of the technical sections of the Westinghouse Club.

Samuel F. Joor, a consulting engineer of Chicago, has joined the American Steam Conveyor Corporation, Chicago, in the capacity of sales engineer. Mr. Joor has had wide experience in the conveyor field, at one time being western manager and sales engineer of the Jeffrey Manufacturing Co. and previous to that, with the Link-Belt Company.

High appreciation of the work of **Lieutenant-Colonel C. W. Watson**, president of the Consolidation Coal Co., as an ordnance officer in France, has been expressed by General John J. Pershing, head of the American Expeditionary force. In a letter addressed to Colonel Watson, General Pershing says, "I wish to express my appreciation of the valuable services which you rendered the American Army as Base Ordnance Officer of Base Section No. 6. You performed tasks of magnitude, constantly surmounting unexpected difficulties and solving perplexing problems with sound judgment and initiative. At all times you were devoted to your important duties and untiring in the energy with which you unfailingly acted. I regret that I was unable to thank you personally before you returned to the United States."

Obituary



Charles Binkley, age 53, a coal operator of southern Illinois, recently died from heart failure at his home in Marion, Ill. He had been suffering with pneumonia for several weeks.

Burr E. Cartwright died on June 17 at his home in Buffalo, N. Y., in which city he was born in 1850. He was interested in the Shawmut Mining Co., whose property he developed.

John J. Broderick died on June 7 at St. Louis, Mo. Mr. Broderick was president of the Broderick & Bascom Rope Co., whose product is used in and around the coal mines throughout the country.

Philip M. Hucke, age 49, died at his home in St. Louis, on June 19. He was general manager of the Kolb Coal Co., St. Louis, and also manager of the St. Genevieve Lime Co. Mr. Hucke was a member of the St. Louis Chamber of Commerce and prominent in the masonic fraternity.

Major Granger Farwell, chairman of the board of directors of the Monarch Coal Mining Co., of Monarch, Wyo., died suddenly in Chicago, May 15. He is survived by a widow and five daughters. Major Farwell entered the army when this country declared war and served until Jan. 10, of this year. Besides being connected with the Monarch company, he was a director of the Diamond Match Co., Utah Gas and Coke Co. and other institutions.

MAJOR GRANGER FARWELL

Coming Meetings

American Institute of Mining and Metallurgical Engineers will hold its fall meeting Sept. 22 to 26 in Chicago, Ill. Chairman Chicago meeting, Carl Scholz, 547 West Jackson Boulevard, Chicago, Ill.

Northeast Kentucky Welfare and First Aid Association will hold a first-aid contest July 4 at Pikeville, Ky. Secretary, E. H. Sowards, Pikeville, Ky.

The Rocky Mountain Coal Mining Institute will meet in Salt Lake City the second week in July, 1919. Secretary, F. W. Whiteside, Denver, Colo.

Mine Inspectors' Institute of the United States of America will hold its annual meeting July 8 to 11 at Indianapolis, Ind. Secretary, J. W. Paul, Pittsburgh, Penn.

The National Commissary Managers' Association will hold its annual meeting August 5-7 at the Sinton Hotel, Cincinnati, Ohio. Secretary, D. J. Eichoff, Manhattan Building, Chicago, Ill.

Pennsylvania Retail Coal Merchants' Association will hold its annual meeting July 23 and 24 at Reading, Penn. Secretary, W. M. Bertolet, Reading, Penn.

National Exposition of Chemical Industries will hold its fifth annual meeting at the Coliseum and First Regiment Armory, Chicago, Ill., during the week of Sept. 22. Manager, Charles F. Roth, 417 South Dearborn St., Chicago, Ill.

The National Safety Council will hold its annual meeting Oct. 1 to 4 at Cleveland, Ohio. Secretary, S. J. Williams, Chicago, Ill.

Industrial News

Cincinnati, Ohio—The B. A. Vesche Electric Co., of 327 East Sixth St., of this place, announces that the address of its eastern sales agent is 110 West 40th St., New York City.

Cleveland, Ohio—The Sullivan Machinery Co. announces the establishment of a new branch office at Room 810 Park Building, Cleveland, Ohio, under the management of Ralph T. Stone, for several years past sales engineer associated with the New York office of the company.

Huntington, W. Va.—The Link-Belt Co., of Chicago, has opened a new office at this place. George S. Jaxon, one of the company's engineers, who for many years served the West Virginia field, has been made district manager with headquarters in the Robson & Prichard Building.

New York, N. Y.—The Dominion Asbestos and Rubber Corporation, with executive offices at 154 Nassau St., New York City, has recently opened branches in Albany, N. Y.; Atlanta, Ga., and Allentown, Penn. In January, 1919, the capital stock of the company was increased to $100,000.

Petersburg, Ind.—The Gladstone Coal Co., which operates the Gladstone coal mine, three miles north of this city, on the Evansville & Indianapolis R.R., is completing a new tipple and will increase the working force to 100 men within the next few months. Electric power will be used.

Oil City, Penn.—The Oil City Oil and Grease Co., of this place, has been authorized to increase its capital stock from $80,000 to $200,000. D. J. Cavanaugh is treasurer. This expansion means increased business and reflects most favorably on the excellence of the products of this company.

Yorkville, Ohio—The erection of 47 houses was begun at the Dorothy mine of the Youghiogheny & Ohio Coal Co., west of here, recently. This will make a total of 100 houses at the Dorothy and Bud mines. It is said the number will be doubled eventually. A large store building will also be erected.

Pittsburgh, Penn.—The Safety First Supply Co., of this place, has found it necessary to move to larger quarters on account of the continued increased business of the company. The entire building at 107 Third Ave., Pittsburgh, is devoted to the manufacture and distribution of appliances for safety first aid and welfare.

California, Penn.—Extensive additions and enlarged operations at the Vesta mines of the Jones & Laughlin Steel Co. are being planned as a result of the completion of the first battery of byproduct ovens at the big steel plant. Operations have been resumed at Vesta No. 4 after a four months' shut down.

Huntington, W. Va.—C. W. Jones, W. E. Minter and associates have recently completed arrangements for the purchase of coal properties in Fayette County, and are planning for extensive development at an early date. The tract comprises about 2500 acres. It is understood that the plans provide for an annual capacity to exceed 200,000 tons.

Olcott, W. Va.—The General Underwriters, Inc., has acquired the Penn-Virginia Coal and Coke Co. and the Black Band Fuel Co., the latter being a well known company in Kanawha County where the formal transfer was made. The consideration was approximately $100,000. A further development of the Black Band property is insured.

Pruden, Tenn.—The Pruden Coal and Coke Co., of Knoxville, is understood to be planning the development of approximately 2500 acres of coal properties located in the Pruden district. Complete equipment for an up-to-date plant will be installed. It is proposed to have an initial capacity of about 300 tons daily. V. M. Hacker is president.

Cincinnati, Ohio—Goodin, Reid & Co. of Cincinnati, Ohio, has changed its name to Goodin, Reid and Co., of New York, and has removed its main office from Cincinnati to 41 Union Square West, New York City. The company will still maintain its Pittsburgh office at 913 Farmers Bank Building and shipments will continue to be made from Cincinnati.

Washington, D. C.—According to Railway Administration figures the mines and oil wells of the United States furnish 55.75 per cent. of the tonnage hauled by the railways. The material manufactured from ores and minerals produced from American mines and oil wells furnish 25 per cent. of the remaining tonnage. This ratio has existed in a greater or less degree for many years.

Buffalo, Tenn.—The Buffalo Coal Co., of Knoxville, recently incorporated with a capital of $75,000, is arranging for the commencement of work at an early date on the development of approximately 1500 acres of coal properties located in the Buffalo district. It is understood that the company's plans provide for an initial capacity to exceed 500 tons per day. A. B. Day is president; and Milton T. DeVault, secretary.

Taylorville—The shaft of the Springfield Coal Co. has been closed down indefinitely. The mine has been working only one day a week since January 1 and the shutdown will not mean a great loss to the miners, except that they had been holding on with the hope that there would be an abundance of work in the future. It is believed that there will be no more work at this mine until fall. The other mines in the Taylorville vicinity are working full blast, extra men being required at a number of the mines.

Coalwood, W. Va.—Arrangements are being made by the Carter Coal Co. for extensive improvements at its various plants. The plans include the construction of a large new steel tipple and automatic hoist at the Coalwood works, as well as the construction of a number of new miners' houses; improvements at the Seaboard and Coaldon plants, and other work to increase the present capacity. At the present time the company's holdings approximate 40,000 acres of coal properties located in four states. J. W. Carter is vice-president.

Fairmont, W. Va.—The Domestic Coke Corporation is making rapid progress on the installation of its large new local plant, estimated to cost in excess of $3,000,000, and it is expected that construction work will be completed by the first of the coming year. The plant will comprise a battery of 60 Koppers ovens with byproduct recovery apparatus, to have a daily carbonizing capacity to exceed 1000 net tons of coal. The Koppers Co., Pittsburgh, Penn., is the contractor. Charles V. Critchfield, Cleveland, O., is vice-president of the corporation.

Palmer, W. Va.—A million-dollar firm to be known as the Jones By-Products Coal Co., has been organized by well known Delaware and Pennsylvania business men to operate at this place in a comparatively undeveloped region. While the plans of the company have not been made public it is understood that a large byproduct plant will be constructed and operated. The company was organized by Robert H. Jones, of Wilmington, Delaware; H. Chester Johnson, John E. Bassett, and Randall F. Collins of Philadelphia and John M. L. Black of Villa Nova, Penn.

MARKET DEPARTMENT

EDITED BY ALEX MOSS

Weekly Review

Good Grades of Bituminous Coal Already Contracted For—Present Is Best Time to Purchase Fuel—Anthracite Domestic Sizes in Good Request—Production Inadequate to Meet Demand, Which Is Insistent

THE disinterestedness evinced by many large consumers of bituminous coal at the present time can lead only to one result this winter—a coal shortage. Mines are still losing on an average of two days a week because of lack of orders. The rate of production is at present about 30 per cent. below that of last year, and is only sufficient to take care of current consumption.

Operators still hold fast to the belief that the signing of peace will bring in its wake the long-expected activity for American industries, and that many large consumers will thereupon change their present lackadaisical attitude toward their future coal needs.

Business, however, is picking up, though slowly. It is not at all improbable that the next few weeks will witness the inauguration of a new era in market conditions. No contracts are being signed, and those concerns that have failed to cover themselves for their future requirements will find when they come into the market not only higher prices, but a dearth of the good grades of soft coal, the output of which for the coming year has already been contracted for.

Add to this the by no means remote possibility of labor trouble at the mines, labor shortage, inadequate car supply, higher freight rates and poor transportation conditions—and the reasons why the immediate moment is the psychological time for the purchase of coal become readily apparent. In a short while the complexion of things will have changed.

Medium and low grade coals move slowly. Producers of the better grades are refusing new business. Gas coals are in good request, and the export coal situation is improving. The general average of market prices is on about the same level it has occupied for the past month.

During the week ended June 14 there was produced 8,782,000 net tons of bituminous coal as against 8,917,000 net tons for the preceding week.

Demands for the domestic sizes of anthracite are nothing short of strenuous. The cry for egg and stove coal is most insistent. Chestnut, also, is coming in for a goodly share of the favor shown toward the larger anthracite coals at this time. The mines are working steadily, but the output could be much greater if sufficient labor were available. Many anthracite mines are now producing at only from 60 to 65 per cent. of their maximum output capacity.

Good tonnages of hard coal are moving to Canada, to the West, and to New England points. Efforts are being made to prevent a serious shortage of anthracite in any section of the country next winter As in former years, those sections more remote from the source of supply are being catered to first.

During the week ended June 14, about 1,685,000 net tons of anthracite were mined, bringing the total output for the calendar year to date up to 35,180,000 net tons compared with 44,890,000 net tons in the corresponding period of last year.

WEEKLY COAL PRODUCTION

A slight decrease in the production of bituminous coal was recorded for the week ended June 14 The estimated output is 8,782,000 tons, compared with 8,917,000 tons in the first week in June, and 8,724,000 tons in the week ended May 24.

The best time in the year for laying in stocks of coal for next winter is rapidly passing, with no evidence of general buying for this purpose. The rate of production has not varied greatly since the middle of May, and averaging about 30 per cent. below last year, is apparently just sufficient to meet current consumption.

The production of anthracite in the week ended June 14 is estimated at 1,685,000 net tons, about the same as the preceding week, but nearly 15 per cent. below the estimated output for the corresponding week of 1918. The total production for the calendar year to date is estimated at 35,180,000 tons, compared with 44,890,000 tons in the corresponding period of last year.

Reports from the operators for the week ended June 7 show no general improvement in the market for bituminous coal. The mines lost on the average two days in the week because of lack of orders, which is a slightly smaller loss on this account than in May. With the exception of a few districts the railroads are giving practically full car supply, but in both the smokeless and high volatile fields of southern West Virginia car shortage is already becoming a limiting factor. Several districts, however, reported to exceed 80 per cent. full-time operation; the Pittsburgh, Westmoreland and nearby fields and Somerset reaching that mark for the first time this season.

The production of beehive coke in the week ended June 14 is estimated at 297,500 net tons, compared with 271,400 tons in the week ended June 7, a gain of about 26,000 tons, or more than 9 per cent. Although the production of beehive coke has been slowly but steadily increasing in recent weeks, at the present rate of production it is less than 45 per cent. of that of the first half of June, last year. The increase in production in the week ended June 14 was general. Colorado and New Mexico in particular recorded an output nearly twice that of the first week in June.

The shipments of lake coal continue to exceed the million-ton rate per week. The total dumpings in the week ended June 7 are reported at 1,074,000 tons, nearly 70,000 tons greater than the previous week, and more than 300,000 tons, or 41 per cent. greater than the corresponding week of last year. The total lake coal dumped to June 7, this year, exceeds the total for the corresponding period of last year by nearly 1,200,000 tons, or 25 per cent.

BUSINESS OPINIONS

Marshall Field & Co.—Current wholesale distribution of dry goods ran about the same compared with the corresponding week of 1918. More customers were in the market than during the comparative week of last year. Retail business continues excellent. Orders from road salesmen for both immediate and future delivery were much greater in volume than for the corresponding week of 1918. Collections are satisfactory.

The Iron Age—Volume of new business and rate of production in steel has undergone little change in June. The improvement of three weeks ago has been held, without the signs that usually attend a regulation buying movement. The amount of new manufacturing capacity that is projected in metal-working lines in the Middle West, particularly in the Detroit district, and the repair and new construction work laid out by a number of steel companies, are outstanding features.

Dry Goods Economist—The export demand for American textiles continues to grow. The call for certain goods now exceeds the capacity of the mills that produce them and has made it necessary for exporters to seek the aid of jobbers and converters in order to make shipments. One leading printer of cotton fabrics is said to have export orders for 10,000 cases of goods. A heavy demand for raw cotton and for cotton fabrics is anticipated, but for the present there is limited activity among dealers in the staple.

American Wool and Cotton Reporter—On the basis of supply and demand, the wool industry is in a stronger position than in the past, and therefore the profit margins are likely to be more regular and somewhat larger. No great change in the situation is looked for until the buying power declines greatly, or the supply is largely increased, and neither of these changes is anticipated soon. Raw cotton has been particularly weak during the week under review with a decline running up to about $20 per bale. The decline was rather unexpected by many, but is perhaps justified on the basis of the rapid advance which had occurred and because of the uncertainty as to the consumption of cotton in other countries.

Atlantic Seaboard

BOSTON

No distinct price movement as yet. Steady improvement, however, in general situation. The trade notices a disposition to stock coal. Gas slack quoted at low figures. Navy Department arranges for a "pool" at New York. Little demand at New York and Philadelphia piers. Hamp-

ton Roads resumes dumping on settlement of trainmen's strike. Anthracite behind on shipments.

Bituminous—Although there have been scattered instances where select grades have been sold at prices slightly advanced, there has yet developed no pronounced upward movement. The market here seems more than anything else to be "marking time." While this is not unusual in New England for the early weeks of summer, the trade really anticipated a much more active market in June this year. There is still room for a good deal of optimism, however, for the business boom is coming and not for any extended period in the future will 50 per cent. output be enough to run the railroads and turn the wheels of industry. The present state of the market only goes to show that this territory was more heavily overstocked than was supposed, and that even now there are large plants taking current supply from the mines and having still untouched large reserves that were accumulated last season. So long as mining continues on the present basis, without material loss of tonnage, There are no surface indications of shortage the coming season, so far as this territory is concerned. The rub is expected to come when either present output can no longer be maintained, or other sections of the country increase their requirements.

The undertone continues decidedly favorable to a more active market, slow as it may appear in coming. Buyers find that special kinds of coal are not so easy to secure and there is more or less maneuvering to get shippers to agree to contracts. Operators have shown more disinclination the past fortnight to sign up for extended delivery, and even September orders are not sought in the same eager fashion that was characteristic but a few weeks ago. Certain shippers are beginning to say they would rather not take business, at least for the present, and wait for developments later on when higher prices seem assured. There are still steam-users of importance who have not yet bought for fall and winter, but these are exceptional cases. The bulk of the buying hitherto has been to meet only part requirements, leaving it to later in the season to secure the balance needed. It is some of this kind of purchasing that is being done now and on which slightly higher prices have been realized. So far as prices go there is less questioning among buyers; their effort has been directed more to getting suitable fuel, and the gain in this respect is very great. Not in years has there been such discrimination between different grades.

There are a good many smaller buyers, 10,000 tons and less, who are already beginning to stock coal. Many of them were hoping to rely upon steady shipments during the next six or nine months, but there are so many uncertainties that they concluded to take the more prudent course. Certainly it would be hard to figure out how coal is going to cost any less between now and next April. It seems pretty well established that the Government will not increase freight rates, but it is at least equally certain that under private management the railroads will seek to recoup themselves if costs continue to mount.

Slack coal has been freely offered the past week, in part reflecting the better demand for prepared coal in other markets and also indicating the market preference of buyers here for the low volatile coals. The Fairmont gas coal shippers are especially active with spot prices as low as $1.40 per net ton. They are at a disadvantage in tariffs, however, for in a considerable part of this territory they are under an adverse differental of at least 35c., and in other cases 60c., for there are producers of slack in Central Pennsylvania who can ship at the minimum Clearfield rate. In the Pittsburgh region prices on slack are almost as low as in Fairmont, several quotations of $1.50@1.60 having been made.

It is understood that the Navy Department has arranged for more than 20 different coals to be shipped regularly to a Navy "pool" at the New York loading piers. This is recognized as an effort to keep coal in steady supply for all requirements and emergencies. Perhaps no better line could be had on the prospective market for steam coal than the official attitude indicated by this move. It is conceded that several coals have been given classification in Pool 71 (coals on the Navy supplementary list) that in normal times would hardly be requisitioned for Navy purposes, but with the outlook as at present the authorities could not prudently do otherwise.

At the New York and Philadelphia piers there is no improvement in the spot market. The quality grades are held firmly and usually are sent from the mines only on staple business, but on the medium and fair coals there is almost no movement worth mentioning. All-rail delivery has the call in most of New England and almost it seems as if the market for water coal were being increasingly restricted. The higher grades from Pennsylvania costs nearly as much alongside in our harbors as the smokeless coals from Hampton Roads, and where both coals are accessible the latter are likely to have the preference at any moderate differential.

The trimmers' strike at Norfolk was settled and service resumed on the 16th instant. Much inconvenience was caused the several shippers but the market here can hardly be said to suffer for any lack of coal in consequence. Prices are firmer, however, and now that practically all the tonnage has been sold that could readily be placed on the lower figure there is a disposition to adhere to the $5.14 basis f.o.b. vessel. Much is said about the enormous demand expected overseas when peace is signed, and of course there is a steadily increasing tonnage loaded for export; but there has been no distinct trend of prices upward, as yet.

Current quotations on bituminous at wholesale range about as follows:

	Clearfields	Cambrias and Somersets
F.o.b. mines, net tons	$2.15@2.75	$2.75@3.35
F.o.b. Philadelphia, gross tons	4.27@4.95	4.95@5.50
F.o.b. New York, gross tons	4.62@5.29	5.29@5.85
Alongside Boston (water coal), gross tons	6.10@6.85	6.90@7.35

Georges Creek is quoted at $3.20 per net ton f.o.b. mines.

Pocahontas and New River are being quoted at $5.04@5.24 per gross ton f.o.b. Norfolk and Newport News, Va. Alongside Boston the same grades are being offered at a range of from $7.24@7.44, and on cars Boston and Providence at from $7.50@7.90 per gross ton, the latter being the contract price f.o.b. cars for deliveries to April 1.

Anthracite—On domestic sizes the demand continues most insistent. A slight easing up on chestnut has been noticed lately, but on egg and stove the movement is extremely slow whether by rail or by water. There is not this year the strong arm of the Fuel Administration to favor New England on anthracite, and all the shippers are faced with extraordinary pressure to get coal forward to all sections and a much less tonnage for distribution. The larger cities, too, have increased their needs because of large increases in industrial population.

NEW YORK

Heavy demand for domestic sizes of anthracite continues. Canadian dealers offering inducements for coal. Heavy tonnages being sent into the West. All-rail trade heavy. Steam coals long in supply with prices easy. Local bituminous market dull, but line trade picking up. Prospects bright for better business soon. Contracting nearly ended. The better grades of bituminous coal in demand. Exporters report good business.

Anthracite—Conditions in the local market are strenuous. The quantity of egg, stove and chestnut, particularly the first two named, received here is far too small to meet the demands of the trade. The call for these coals remains strong and dealers are booked far ahead.

Production maintains its usual level. The mines are working steadily, but because of the lack of the required labor to mine the coal the output in many mines is only from 60 to 65 per cent. of what it should be. However, the production figures for the past few weeks show a steady increase, but a vast decrease as compared with a year ago. An effort is being made by the selling agents to distribute the supplies equitably in the hope of preventing a serious shortage next winter in any section of the country.

The demand from the West and from Canada continues heavy with no let-up in sight. Heavy tonnages are being sent forward. It is reported that some Canadian dealers are offering inducements for quick shipments. Shippers covering the New England states say there is a big demand there and that a good tonnage is going forward both by rail and by water.

Dealers handling all-rail coal are in the market for heavy supplies of the domestic sizes. They are complaining of slow shipments but are better situated with respect to stocks than the city retail dealer, inasmuch as most of them have facilities for storing coal which the local dealer does not possess.

Selling agents and shippers are top-heavy with orders for the larger sizes, many of them refusing to book new orders unless the old orders have been reduced through deliveries.

The condition of the market regarding domestic coals has resulted in premiums being asked for some of the so-called independent coals. Not all operators are asking premiums, but it is said that some are quoting prices ranging up to 50c. per ton above the regular company circular.

Chestnut coal is not as short as egg and stove, but dealers are glad to get it. Pea coal is in fair demand and is not long, the call for it being about normal.

There has been no reduction in the quantity of the buckwheat coals coming forward. While buckwheat is plentiful most buyers receive no concessions from the regular quotations, particularly when the better grades are wanted. Rice and barley are more noticeable. Quotations for good grades of rice coal range from $2.30 to $2.50 at the mines, and for barley from $1 to $1.25.

The quantity of the anthracite steam coals on hand has again brought to the front the question of a reduction of sizes. Some of the trade believe that with a reduction of sizes there would be a better opportunity to keep up with the demand for the domestic coals and that the buckwheats would not accumulate as easily as they now do.

Dumpings of anthracite at the local railroad piers for the week ended June 21 were 6046 cars as against 5611 cars the previous week, an increase of 435 cars. There were 2812 cars of anthracite at the docks as against 3112 cars on June 13, a decrease of 300 cars.

Current quotations, white ash, per gross ton at the mines, f.o.b. tidewater, at the lower ports, are as follows:

	Mine	Company Circular
Broken	$5.95	$7.80
Egg	6.05	7.90
Stove	6.30	8.15
Chestnut	6.40	8.25
Pea	5 00	6.75
Buckwheat	3.40	5.15
Rice	2.75	4.50
Barley	2.25	4.00

Bituminous—The situation at this market is dull. There is no buying and yet operators and shoppers see signs of brightness ahead. Some claim that the situation is brighter than last week. They claim to see business picking up slowly and believe that the next few weeks will see wonderful changes in conditions.

In this harbor there is little coal moving unless it is on contract. Buying is almost at a standstill, but there are some who are anxious at this late day to close contracts. There are practically no new contracts being considered unless they are for the poorer grades. The better grades have all been taken up and for that reason quotations for contract business have been practically removed from the market.

The labor situation is likely to play a prominent part in the coal industry for at least the balance of the winter. With peace near at hand there is a bare possibility that the mine workers may ask for an increase in pay, it being understood that their present agreement with the operators terminates upon the declaration of peace by the President, or it may continue in force until March 31, 1920. Some operators are looking at that phase of the situation in booking future business, while there are others, and they are by no means small in number, who do not anticipate any trouble. Labor is short-handed and operators hold out little hope that the situation will improve.

Shippers expect that buying of the free coals will soon pick up, due to the smallness of storage piles in most manufacturing places. They maintain that these customers, most of whom have failed to make contracts, are not willing to take any further risks for the market and will soon come forward with orders for coal.

The demand for the better grades is strong and orders have been booked for

weeks ahead; in fact, it is said that some operators have their output sold for the next six weeks and are refusing new orders. There is a good demand for gas coal.

The trade here is advising against excessive shipping to this harbor in the expectation of finding a ready market. Fears are entertained of an overstocked market which may result in price-cutting in order to move the coal. Producers are advised to ship only when they have a market, thereby avoiding the danger of being forced to dispose of their product at a loss.

There has been an improvement in the export situation which is encouraging. With the vesels coming into this harbor steadily increasing in number the bunker business is healthy. Some tradesmen say that were it not that many of the bottoms are equipped with oil burners it would be impossible with production as it now is to supply all the coal necessary.

During the week ended June 21 there were 5560 cars of bituminous coal dumped at the local railroad docks, as compared with 5748 cars the previous week, a decrease of 188 cars. On June 21 there were 4196 cars on hand at the docks as compared with 4394 cars on June 13, a decrease of 198 cars.

Quotations on some of the various pool coals f.o.b. this harbor are as follows:

Pool No. 9	$5.30@5.50	Pool No. 11	4.65@4.90
Pool No. 10	4.85@5.00	Pool No. 71	5.30@5.50

Following are quotations on various coals, per net ton at mine:

South Forks (Best)	$2.95@3.25
Cambria (Best)	2.75@2.95
Cambria (Ordinary)	2.35@2.50
Clearfield (Best)	2.75@2.95
Clearfield (Ordinary)	2.35@2.50
Reynoldsville	2.50@2.75
Quemahoning	2.75@2.95
Somerset (Best)	2.75@2.95
Somerset (Poor)	2.15@2.35
Western Maryland	2.25@2.50
Fairmont	1.75@2.00
Latrobe	2.10@2.25
Greensburg	2.25@2.35
Westmoreland ¾ in.	2.60@2.75
Westmoreland run-of-mine	2.35@2.50

PHILADELPHIA

Anthracite activity shows no sign of abatement. Full production absorbed. Dealers endeavoring to accumulate stocks. Moderate premiums asked. Retail demand strong on all sizes, especially egg and stove. Pea moving steadily. Buckwheat gains strength. Rice and barley very weak. Bituminous displays signs of strength. Consumers more interested. Some contracts closed. Bigger business predicted soon. Prices firm.

Anthracite—There is no sign of weakening in the market for prepared sizes. It is true that many of the smaller dealers will have delivered by July 1 practically all their orders, with the possible exception of stove coal. If the retailers who handle heavy tonnages have materially reduced their accumulation of orders it certainly does not show in their buying. A canvass of the numerous yards located here shows, with few exceptions, seriously small stocks. Every day more dealers are coming to the conclusion that there are troublesome times ahead for those in the trade who go into the fall season without full bins. In their advertisements they are freely predicting that the public will face a shortage, with higher prices, next winter.

All shippers consulted show no hesitancy in prophesying an indefinite demand for all family coals. We hear of premium prices being offered from other markets that are surprisingly high, especially on stove, but as usual this market is not paying any unusual prices. We heard of several instances where as much as 70c. premium on stove was asked, but no one is willing to admit that a sale was made at that price. In fact, we doubt if any of the shippers are charging their regular trade more than 30c. above company circular. Needless to say the big companies are adhering to their schedule of prices on all sizes from broken to No. 1 buckwheat inclusive.

Egg is in poor supply and the call for it is far greater than in any normal year. It would probably require no enormous tonnage to satisfy the immediate demand, but because so little of it is coming here most dealers are extremely short of it. The call for stove is so general and persistent that no producer will give any buyer any encouragement as to the ability of satisfying needs in the near future.

As last week, there is a heavier tonnage of chestnut in the yards than either egg or stove, but the retail demand continues quite strong on all sizes. Chestnut is apparently causing the shippers no concern, as they report the orders from the West show no signs of any weakness in that market. To the satisfaction of the shippers the pea-coal demand keeps up beyond their earlier expectations. Several of the larger buyers have recently placed orders for substantial blocks at circular. They now claim they had not been waiting with the hope of lower prices on this size, but that they have been too busy to spare their yard help to unload and store it. We believe that some of the poorer grades of pea coal are being moved by the shippers refusing to accept orders for the larger sizes unless they carry a proportion of pea with it.

Among the dealers the report is common that they are receiving little new business. This is particularly true in the industrial districts, where with the business on a strictly cash basis, many of the buyers are not yet in position to stock coal for the winter. One of the big retail companies in order to meet the argument of many customers that their houses might be sold before they used the coal, have used big space to advertise the fact that in case they have to move the incoming tenant would be more than glad to purchase the coal in the cellar. Of course there will be ordering right along and we are fully of the opinion that the people are even now becoming strongly cognizant of the fact that coal will be difficult to get next fall and winter.

In the steam coals buckwheat continues in its gradual gain in strength. Several independent houses who had been accepting business at considerably less, now report refusing all orders that do not carry the $3.40 price. Rice is slow to respond and continues troublesome. With the heavy tonnage now in storage we expect to see low prices on this size for some time. We hear of $2.50 being quoted, but believe sales are made at considerably less. Barley remains in the discard and one authority states that no reasonable offer would be refused.

Bituminous—We believe it can be said after a careful canvass of the trade that there is a stronger tone to soft coal. Consumers are becoming alive to the fact that they are going to need fuel and are also more keen in their desire to take in supplies. While many of the producing companies have all the contract tonnage they desire, there are some other concerns slow at first to go in for agreements, who are now accepting some tonnage from the best trade. It can also be said that big users of coal are really taking in more tonnage now than they are consuming, not wishing to be caught with short stocks next fall, when crop movement might interfere with the shipment of coal.

Yet with all the light buying so far this spring, one authority consulted is of the opinion that there is still more coal above ground now than there was at this time last year due to the extremely heavy stocks which were accumulated last year. The improvement in the iron trade has shown its reflection in the soft coal trade, and there is at this time a feeling of confidence that big business is not far away; some shippers really predict that within 60 or 90 days the demand is likely to be considerably greater than the supply. It was only during the past week that one operation producing high-grade coal actually reported a car shortage. While this was purely a local condition it is indicative of the fact that it will take only a very few weeks to change the entire aspect of the soft-coal trade.

The prices ruling in this market have been about as follows:

Georges Creek Big Vein	$2.90 @ $3.00
South Fork Miller Vein	2.90 @ 3.00
Clearfield (ordinary)	2.70 @ 2.80
Somerset (ordinary)	2.65 @ 2.75
Fairmont Lump	2.50 @ 2.60
Fairmont mine-run	2.35 @ 2.45
Fairmont slack	1.90 @ 2.00
Fairmont lump (ordinary)	2.25 @ 2.35
Fairmont mine-run (ordinary)	2.00 @ 2.10
Fairmont slack (ordinary)	1.70 @ 1.80

Due to the limited demand the matter of labor shortage has not made itself felt, but certainly will by the time orders begin to accumulate in the shipping offices, requiring full working time. No one believes for an instant that the production of last year can be approached, yet on the other hand the demand is likely to be almost as great when the industrial boom arrives, as all fully believe it will.

Lake Markets

PITTSBURGH

Car shortages threatening. Labor scarcity feared. Slack easier, mine-run steadier.

The Pittsburgh district coal market is somewhat stiffer in general tone, not so much by reason of heavier demand as by reason of prospects increasing that coal will be scarce next fall and winter on account of transportation and labor conditions. There has been little if any increase in buying. The steel industry, one of the largest consumers, is running a shade better, now averaging an operation of about 60 per cent. of capacity, against an average of 54 per cent. in May, the lightest month since about the beginning of 1915. It is questionable whether there will be much further improvement in mill operations in July and August, which are normally very dull months in the steel trade.

Car shortages have begun to appear. While they are of little moment in themselves they are held to bear an important augury. For instance, a developing mine that has an old rating of 4½ cars had been shipping 11 cars daily, getting the cars without going to the trouble to secure a new rating, and it was suddenly notified it would be cut down to its rating of 4½ cars. As a developing mine this mine could secure more cars by formal application.

Some uneasiness is felt by coal operators that there may be labor difficulties before the end of the coal year, through the miners taking advantage of the fact that the present wage arrangement expires by limitation when the peace proclamation is issued. Common labor is far from plentiful, while miners are indisposed to work full time.

The general average of market prices is about the same as for two or three weeks past, but in the past week there has been a slight further softening in steam slack and at the same time a little stiffening in mine-run, whereby we quote steam slack at $1.40 minimum instead of $1.50 and mine-run at $2 minimum instead of $1.90, the general run of prices being as follows: Best grades gas coal: Slack, $1.65 @ 1.85; mine-run, $2.35; screened, $2.60 @ 2.70; Steam: Slack, $1.40 at 1.70; mine-run, $2 @ 2.35; per net ton at mine, Pittsburgh district.

TORONTO

Shortage of stove coal the cause of delayed deliveries. Other sizes available. Dealers advise consumers to substitute egg and nut. Bituminous quiet.

There is no likelihood of dealers overtaking arrears in the delivery of anthracite for some weeks to come, as orders are being received by such dealers as will accept them in greater volume than the supplies coming forward. The principal cause of the delay in filling orders is due to the fact that about 85 per cent. of the domestic demand is for stove coal, while only about 30 per cent. of the shipments received from the mines are of this grade. The dealers are appealing to consumers to substitute egg and nut coal, which can be used to equal advantage in many cases, or mixed with stove coal. They state that the situation would be greatly relieved if this course were followed, as while there is a great shortage of stove coal, they can supply plenty of the other sizes. There is no improvement in the demand for bituminous of which there are ample supplies on hand with a downward tendency in prices.

Quotations for short tons are as follows:

Retail:	
Anthracite, egg, stove, nut and grate	$11.50
Pea	10.00
Bituminous steam	7.50
Slack	6.50
Domestic lump	10.00
Cannel	11.50
Wholesale f.o.b. cars at destination:	
Three-quarter lump	5.75
Slack	4.44

BUFFALO

Some stir in bituminous reported. Anthracite not plentiful enough to meet the demand.

Bituminous—The movement is much as it was. Shippers note an increased uncertainty on the part of consumers as to the chances of getting prompt service when the stir is here. Certain Canadian factory owners are asking jobbers what they may expect in July and August, if the demand stiffens. The reply is that early buying will obviate any difficulty, but that in any case the jobber ought to be advised in time of the change when it comes. Nobody doubts that it will come before long.

Not much coal is moving unsold. It is too risky. None has been reported here on consignment for a long time. In case any comes this way it finds its way to Canada in time to keep that market in a state of depression. The water movement from Ohio ports to the St. Lawrence is dull. A vessel in that trade lately has been unable to get a cargo. The report is that the territory is pretty well filled up. It will take a brisk stir in manufacturing to use up the output.

Slack coal is still weak, both it and mine-run being offered by certain mines at reduced prices. Jobbers for the most part are holding close to old prices and are quoting as follows: Thin-vein Allegheny Valley sizes, $4.65; Pittsburgh and No. 8 five-quarter lump, $4.45; same, three-quarter, $4.30; mine run, $4.05; all slack, $3.65 per net ton, f.o.b. Buffalo.

Anthracite—The supply continues to be less than the demand. All branches of the trade could use more coal. The mines are running sadly behind their previous output, and there is fear of a bad winter shortage if the output is not increased before long. At the same time, the local and rail demand is not so insistent as it was, and the shippers hope to be able to turn in a heavier tonnage to the lake trade soon. All lake ports that take coal by water are short of their usual quota. It is said that the St. Lawrence River and Lake Ontario ports are as deficient as are the upper-lake ports.

Anthracite prices in this market remain as follows:

	F.o.b. Cars, Gross Tons	At Curb Net Tons
Grate	$8.55	$10.20
Egg	8.65	10.40
Stove	8.90	10.60
Chestnut	9.00	10.70
Pea	7.20	9.15
Buckwheat	5.70	7.75

The loading to lake vessels is as brisk as receipts will permit. Shippers would like to turn everything in that direction for a while, till the shortage is made up, for tonnage is plentiful and that may not be the case all the season.

The amount loaded for the week is 117,250 net tons, of which 34,600 tons cleared for Chicago, 30,300 tons for Duluth and Superior, 25,950 tons for Milwaukee, 3000 tons for Marquette, 2600 tons for the Sault and 800 tons for Mackinaw.

Freight rates continue quiet at 60c. to Chicago, 50c. to the Sault and Mackinaw, 47½c. to Milwaukee, 42½c. to Duluth and Marquette.

CLEVELAND

Consumption of coal in northern Ohio continues to gain. Demand is reflecting this condition and prices are firmer. Domestic demand is being maintained surprisingly for this time of the year.

Bituminous—Industrial operations are rapidly approaching normal, with consumption of steam coal keeping full pace. Interest in the coal market is increasing each week. Talk of "good times" appears universal, and it is believed that the middle of next month will see coal consumption back close to the war level.

Slack demand is much better, and the price is much firmer. Around $2 continues the quotation on slack, compared with $1.35 a short time ago. Mine-run is hovering around the $2.10 mark, and it is not believed a great deal could be had for less. Talk of $2.50 slack in the winter is freely heard, and mine-run around $2.60 to $2.75 is another prediction.

Southern and eastern Ohio mines still are on a 55 to 60 per cent. operating basis. A shortage of cars is an every-other-day feature now. The chief restricting factor, however, is lack of labor. Operators fail to see how this can be remedied. Aliens are flowing out as fast as steerage accommodations to Europe can be had.

Anthracite and Pocahontas—The anticipation of a 30-cent increase the first of next month by dealers who have not tacked on the 20-cent advance already authorized, has prompted some buying of anthracite. Demand for Pocahontas is larger than that for anthracite and more difficult to meet. It is believed that Aug. 1 will see a large percentage of next winter's need of anthracite and Pocahontas filled.

Lake Trade—Loading of bituminous coal at Lake Erie ports last week amounted to 1,122,000 tons, and this week will total about 1,050,000 tons. Both cargo space and tonnage seem a trifle decreased this week. May loading probably will be around 4,000,000 tons, exclusive of vessel fuel. Some upper lake dock operators are complaining of the slow movement of bituminous from the docks. In May only 12,067 cars of bituminous left the upper lake docks, compared with 12,913 cars in May 1918, and 16,389 cars in May, 1917. For the five months ended with May 31 the number of cars moved from the docks has been 71,382, compared with 89,800 cars in the corresponding period of 1918, and 114,367 in 1917.

Prices of coal, per net ton, delivered in Cleveland are as follows:

Anthracite:	
Egg	$10.85 to 11.05
Chestnut	11.15 to 11.35
Grate	11.05
Stove	11.05 to 11.25
Pocahontas:	
Forked	9.00
Lump	8.25
Mine-run	7.20
Domestic bituminous:	
West Virginia splint	7.75 to 8.00
No. 8 Pittsburgh	6.10 to 6.35
Massillon lump	7.30 to 7.40
Steam coal:	
No. 6 slack	4.20 to 4.40
No. 8 slack	4.70 to 4.95
Youghiogheny	4.85 to 5.15
No. 8 ¾-in. lump	5.40 to 5.55
No. 6 mine-run	4.40 to 4.50
No. 8 mine-run	4.80 to 4.95

DETROIT

While demand for domestic coal is improving, steam coal is difficult to sell, with prices showing occasional concessions.

Bituminous—Consumers of steam coal in the local market have not yet overcome their apparent reluctance to commence stocking up. Orders coming from them are described as scattering and in small amount, according to jobbers and wholesalers. Reports coming to the jobbers indicate a somewhat unsatisfactory condition as regards car supply in certain West Virginia districts from which part of Detroit's supply is derived. Though the situation is causing no serious trouble yet, it is considered an indication that there is likely to be a less free movement of shipments as the season advances and other uses for cars become more pressing.

With the present movement of coal to Detroit almost unobstructed, the light buying demand for steam coal is curtailing shipments. Considerable coal is finding its way into the market, however, and a large part of the stock is fine coal. Jobbers say there is a moderate amount of coal unsold on tracks, and assert the amount is being magnified in the estimation of some buyers from the circumstance that they are solicited by several brokers offering the same consignment.

Lump of the West Virginia gas and splint type is offered at $2.75, with three-quarter lump at $2.50, mine-run $2.10 to $2.25, and slack $1.85, these quotations being for short ton, with freight and war tax to be added. Hocking domestic lump is quoted at $2.50, mine-run at $2, and slack at $1.50. It is admitted sales of slack have been made at a lower price, transactions having been reported at $1.25.

Smokeless is not reaching the market in very large quantity. There is a small amount of mine-run which is quoted at $2.75 to $3.

Anthracite—High temperatures have curtailed the buying of anthracite for household consumption. Dealers are continuing their campaign of publicity in the effort to encourage early distribution. Shipments are not of large amount, but retailers have a fair amount on hand.

Lake Trade—Shipments over the lake routes are being maintained to fair volume, though carriers are finding it necessary in some instances to shift from one loading dock to another to complete cargoes. Scarcity of downbound cargoes diverts an unusual amount of tonnage to the coal trade.

COLUMBUS

With a better demand for steam sizes and the lake trade going forward actively, the Ohio coal trade is in better shape. Screenings are still a drag on the market. Prices are stronger in most producing fields.

The best feature of the Ohio coal trade is the better demand for steam grades, with the exception of screenings. Mine-run is in better demand and purchasing agents for large plants are in the market for a considerable tonnage. Reserve stocks are being used up to a certain extent, and as a result more activity is displayed in contracting. Operators and distributors believe that the worst of the slump in steam business is now over and that there will be a steadily expanding trade. Iron and steel plants are using a larger amount of coal, and the same is true in certain lines of general manufacturing.

The lake trade is going along nicely with a fair tonnage being moved from Ohio and West Virginia mines to the Northwest. Most of the lake contracts have been made, so there is little opportunity to contract for lake tonnage. Dock interests are busy moving fuel to fill their docks. The movement off the docks to interior points has started.

The domestic trade is still rather slow as consumers are not buying to any great extent. But there is a better feeling in retail circles as householders are making inquiries regarding their fuel supply for the coming winter. The best demand is for the fancy grades, which are higher in price. The short time strike on the Norfolk & Western R.R. caused a flurry in Pocahontas, and some was sold at $6. The regular price for Pocahontas lump is around $5. West Virginia splints are selling well. Hocking and Pomeroy grades are also being bought more liberally, but there is little stocking of those varieties on the part of retailers. Retail stocks are not large.

Production is holding up well, despite the labor shortage which is appearing in some districts. The eastern Ohio field reports about 75 per cent. production and the same figures are reported from Pomeroy Bend. The Hocking Valley, Jackson and Cambridge fields are producing about 65 to 70 per cent. of normal.

CINCINNATI

Demand steady. Not much coal being stored. Prices being maintained.

The demand for all kinds of coal in this market continues steady. Orders are coming in nicely for both immediate and future delivery, with the volume of business being for immediate delivery, however. Dealers in all sections of the city find that there is not the demand for coal for storage this season that there was last year, since many of the coal users in this city have stocks left over. This seems to be especially true of the domestic users, who after stocking up last season for a severe winter encountered mild weather. Consequently their stock of coal was not much depleted. Many householders, however, are laying in quite a stock of smokeless coal, which was unobtainable here last year.

Manufacturers refuse to believe the dealers when they say there is danger of a shortage, and despite all the pressure that can be brought to bear they continue to buy only for their daily requirements. There is quite a good business being transacted by "snowbirds" in this city.

The prices on all grades of coal continue stiff. Some dealers make a specialty of going about 25c. below the market price on coal to stimulate buying at this time, but they are few and far between. The demand for steam coal continues steady, but few orders are being placed for lump coal at this time.

LOUISVILLE

Producers stocked with block orders for June and to about middle of July, many refusing to quote new business. Domestic situation tight, with steam market loose. Prices holding fairly well.

Many of the Kentucky producers are refusing to make quotations on block coal as they have business to run them to about the middle of July and cannot take care of additional business without orders for steam coal, which is still sluggish. It is believed that a better demand for screenings and mine-run will develop about the middle of July, resulting in better prices all around, and enabling the producers to get out a larger volume of block coal without being tied up with the resulting screenings.

The demand for block as a whole has been very good, and mine-run is moving somewhat better; but the nut and slack

situation is about the same as it has been, with industrial consumption not great enough to take care of the output.

Eastern Kentucky is operating around four full days per week, with some mines doing slightly better. It is held that they would all be operating full time if the steam market was right. There is still a considerable labor shortage in some districts, but the car supply is slightly better as a whole.

In western Kentucky things are still slow, with mines doing about two days a week, and scratching hard for business. Block coal is showing some improvement, but steam is very dull.

Such few mines as are quoting prices on eastern Kentucky block are asking $3.35@3.50 per ton for their coal, although such coal would be selling at around $3 if the screenings could be disposed of profitably.

Kentucky mine prices are as follows:

	Eastern Kentucky	Western Kentucky
Block and egg	$3.35@$3.50	$2.30@$2.55
Run-of-mine	2.25@2.40	1.90@2.00
Nut and slack	1.65@1.90	1.60@1.75

BIRMINGHAM

Steam market quiet, some contracts being signed by industrial consumers. Operators await developments in railroad purchases. Domestic market strong, the supply continuing short.

While some few contracts are being signed up by industrial interests for steam-coal requirements for the next twelve months, chief interest is now centered in the course to be pursued by the railroads in regard to renewing contracts for fuel for the ensuing year. The Southern Ry. has rejected all bids from this district, and is reported to have purchased some coal in the Tennessee field, although, on the other hand, operators in that field, it is stated, were unable to furnish the Southern the tonnage of coal normally taken from that district. Nothing definite can be learned as to just what action has been taken by this line. The Seaboard, so it is understood, has contracted for 140,000 tons of Big Seam coal from one of the larger commercial operators, and 40,000 tons of Carbon Hill coal from a combination of small operators in that field. Other lines in the district have taken no action as yet on renewal of contracts. Some coal is now going through the ports of Mobile and New Orleans to Cuban and South American interests, though this tonnage is necessarily limited by lack of bottoms, which condition is expected to be relieved by the allocation of more ships to these ports in the near future.

The domestic market is still strong, and lump coal is difficult to obtain, and this condition will not be relieved until such time as the steam market materially improves. Premium prices can be obtained for any free coal that is made available.

Coke

CONNELLSVILLE

Contracting for second half begins suddenly, terms being practically uniform.

Buyers and sellers suddenly found a basis on which they could get together for the making of contracts for furnace coke for second half delivery, and as a result fully one-half the business that was in prospect has been put through. It seems the way was blazed by the Oliver & Snyder Steel Co., itself a newcomer in the merchant field, and thus not tied down by previous practices while at the same time being able to offer one of the very best cokes in the region. This company's coke has gone exclusively to the Steel Corporation for many years, but the corporation quits with the expiration at the end of this month of the present three-year contract. The company has three plants, in the heart of the old basin, with a total rated capacity of 70,000 tons monthly, but on account of prospective operating and transportation conditions it limited its sales to 50,000 tons, and four contracts have been closed, covering this tonnage. In this and other business done the basis is a ratio of 6¼ to 1, relative to basic pig iron at valley furnaces.

Thus with pig iron at $25.75, nominally at least the present market, coke would be invoiced for the month at $4.12, with four cents rise or fall against each change of 25c. in pig iron. Contracts provide minima ranging from $3.50 down to $2.75, also maxima, but it is altogether unlikely pig iron will change enough between now and the end of the year to call either into play. Somewhat over 100,000 tons monthly has been closed, with about 100,000 tons more business to be done, allowing for some eastern furnaces to switch to eastern by-product coke as they probably will. The spot market is a shade easier, some sales having been made at $3.75 although the regular asking price is $4, with a few operators quoting more.

Foundry coke is in better demand, and while there remains some available for spot shipment at $4.50 the demand runs rather to the higher grades, held at $4.75 and $5. There has been rather free contracting for foundry coke for the second half of the year. Foundries would probably prefer to cover for the twelvemonth, but operators will not quote for the year, except at a stiff advance. The market is quotable as follows: Spot furnace, $3.75@4; second half contracts, 6¼ to 1, against basic pig iron at valley furnaces; spot foundry $4.50@5; second half contracts $5@$5.50 per net tons at oven.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended June 14 at 127,095 tons, an increase of 9446 tons.

Birmingham—The demand for foundry coke in this market is strengthening rapidly and a good aggregate tonnage is being sold. Present quotations on Brookwood are $8, and $9 per net ton ovens is being asked for Yolande foundry. Furnace coke is also experiencing a better demand with the blowing in of several furnaces which have been idle for some time, and is quoted at $6.50 ovens. There is no accumulation of either grade.

Buffalo—The market is a trifle stronger, but no particular activity is yet in sight. Iron ore moves more freely by lake and will probably from this time edge into a full season's activity. If it does not it will soon be impossible to bring down an average supply for the year, and no effort is ever made to supplement the lake cargoes by winter shipments by rail. This would be too expensive. Some new ore is chartering, but no new sales are reported. Coke prices continue at $7.25 to $7.60 for 72-hour Connellsville foundry, $7 for 48-hour furnace and $6.10 for off grades. Finely divided coke is not selling.

Cincinnati—Foundry coke is now in good demand, not alone for immediate requirements, but for shipment over the remainder of the year. Prices seem to be well established, on which basis buyers are showing little hesitancy in covering. It is expected that within the next two weeks virtually all coke contract buyers will have covered for their requirement.

Middle Western

GENERAL REVIEW

Inactivity in market conditions general. Domestic coals expected to increase in price in July. Mines unable to dispose of screenings.

The coal situation in the Middle West does not show the improvement confidently expected of it. The Middle West is perhaps one of the richest manufacturing territories in the United States, and it is discouraging to note that at this late date so many of our industries are in an inactive state. Those operators in our midst who are confirmed and habitual optimists still claim that the market on steam coals will boom as soon as peace is signed, and the various industries receive a chance to figure on what may be expected in the immediate future.

Prepared sizes on practically all grades are firm in price. Lump and egg from the mines producing low quality coal are moving to the railroads, and the same sizes from the high-grade coal fields of Illinois and Indiana are moving to the domestic trade. Prices are firm, and it is generally expected that they will be advanced on prepared sizes July 1.

In southern Illinois this advance will amount to 10c. per ton, bringing the cost of, say, Franklin County domestic coals to $2.95 per ton f.o.b. mines. The demand, however, for high-grade domestic coal is such that the operators could easily advance their prices to $3.15 and $3.25, and still be oversold, but they prefer not to take advantage of the present situation. They are to be commended on their attitude, which is in violent contrast to the New River and Pocahontas operators, who have advanced their prices until their lump and egg sizes are selling at from $4.50 to $5 mines. This contrast in policy is all the more noteworthy because Franklin County coal occupies the same position in the West that Pocahontas et al. occupies in the East. In other words, there are no successful substitutes for either Pocahontas or New River coals in West Virginia, or for Franklin County coal in Illinois.

The situation on screenings is bad, as mines having railroad contracts calling for lump coal are having a serious time in disposing of their fine coals. The steam buyers are not interested, and the only sales made in the past week have been closed on a basis that is below cost to the mines. The situation is serious, and the only hope of immediate salvation is that the signing of peace will bring about an industrial revival that will absorb the screenings now thrown on the market or being put in storage.

Apparently there is a lull in the contract situation, as according to our information practically no coal contract of any size, or importance, outside of railroad business, has been closed during the past week. Operators and jobbers have tried in vain to impress upon the trade the folly of buying coal on the open market, in the very face of conditions as they are at present. Producers and distributors feel that they have done their best, and are now awaiting, with resignation, further developments, which will lead to a coal shortage.

CHICAGO

General dullness in steam trade with demand brisk for prepared sizes.

The local situation differs in no radical extent to conditions experienced by the trade throughout the Middle West. The demand for steam coals is dull in the extreme, and the situation on prepared coals is keen.

The movement of eastern coal into this market continues heavily. It is reported that a number of distributors for the anthracite mines are from three to eight weeks behind on their orders. Some are not taking further business at this time, and others are taking orders only subject to delays.

MILWAUKEE

Coal market experiencing the usual summer quiet. Movement moderate only. Receipts by lake continue ahead of last year.

With the thermometer registering between 80 and 90 deg. daily, the coal market may be said to be in the doldrums. The demand is only moderate, despite a campaign of publicity to induce consumers to stock up early and guard against a shortage of fuel the coming winter. Coke is also moving slowly and the byproduct plants are accumulating large piles in their storage yards. Small sizes of gas coke are being advertised at $9.50, carried in. The Milwaukee Association of Commerce is pursuing an investigation of coal costs from the mines to the Milwaukee consumer in order to determine whether present prices are justified. Coal cargo receipts by lake continue in excess of last year's record. Thus far 205,967 tons of anthracite and 1,026,471 tons of soft coal have been received, a gain over 1918 of 74,456 tons of the former and 376,877 tons of the latter.

ST. LOUIS

Conditions are quiet, with a plentiful supply of all grades of coal and an oversupply of steam, which threatens to become a serious handicap toward getting out a sufficient tonnage of larger sizes. Very little storage coal coming in. Country demand light.

The steam business is demoralized. Throughout the entire Mississippi territory there is an industrial depression that has brought the coal trade face to face with a serious problem, that of taking care of the steam sizes. Many mines are dumping their screenings and smaller sizes on the ground, and some have no more available space in which to do this. Many mines have orders for domestic sizes for three or four weeks ahead and are able to work only one and two days a week on account

of having no sale for the steam sizes. This is affecting the Carterville field more seriously than anywhere else. There has been a noticeable increase in the demand for domestic coal in this field, but most mines are unable to take care of the business. The labor shortage still continues to bother the operators. The car supply is plentiful and the movement is good. Similar conditions prevail in the Du Quoin field. In both of these districts there is a fairly good movement of railroad fuel.

In the Mt. Olive district railroad fuel still helps to keep this field in a somewhat healthy condition. The domestic and steam sizes are going to Chicago and the Northwest, and in a general way the business in this district is satisfactory, everything considered.

The Standard field presents an unusual condition. There is no screening market and no demand for lump, and it is a question as to how long some operators can hold out with the present prices and the light demand. The cost of selling coal from this district has increased several hundred per cent. in the last few months. The preparation is not all that it should be, and there is much dissatisfaction among the miners. The operators, too, appear disgruntled and dissatisfied because the industrial conditions have not shown some improvement.

The present prevailing prices per ton f.o.b. mines are:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
Association:			
Lump, egg and nut	$2.85	.....	.....
Washed Nos. 1 and 2 nut	2.85	.....	.....
Independent:			
Lump, egg and nut	2.75	$2.55 Egg	Lump $2.00 & up 1.75
Washed Nos. 1 and 2 nut	2.85	.....	.....
Mine-run	2.45	2.20	1.60@1.70
Screenings	2.20	2.05	1.35@1.50
3-in. lump	....	2.30	.....
2-in. lump	....	.....	1.75
2x6 egg	....	.....	1.75 & up

Williamson-Franklin County rate to St. Louis is $1.07½; other rates, $0.92½.

I. C. C. Decisions

No. 10237—Seaboard Byproduct Coke Co. vs. Erie Railroad Co., Director General, et al. Submitted Feb. 4, 1919. Decided Apr. 16, 1919.

Rate on byproduct coke, in carloads, from Seaboard, N. J., to Troy, N. Y., found to have been unreasonable. Reparation awarded.

No. 10315 Clark-Davis Coal Company et al vs. Director General, Delaware, Lackawanna & Western Railroad Co. et al. Submitted May, 19 1919. Decided May 21,1919.

Rates charged for the transportation of anthracite coal, in carloads, from Scranton, Penn., to South Utica, N. Y., for delivery by the West Shore R. R., found to have been unreasonable and unduly prejudicial to the extent that they exceeded the rates contemporaneously in effect from Scranton to Utica, N. Y. Reparation awarded.

No. 9734. Middlesboro Kentucky Coal Operators' Association vs. Louisville & Nashville Railroad Company et al. Submitted Mar. 31, 1919. Decided May 19, 1919.

Upon complaint alleging that the Middlesboro mines are subjected to undue prejudice and disadvantage by reason of refusal of the Louisville & Nashville R.R. to establish and maintain rates therefrom to points in the southeast via its line through Corbin, Held: There appears to be no necessity for establishing a route through Corbin. The record does not disclose the basis upon which cars are at present distributed, and the Director General has not been made a defendant. Complaint dismissed.

General Statistics

PRICES OF COAL AT PANAMA CANAL

Coal is being supplied to steamships, including warships of all nations, in transit through the Panama Canal, delivered and trimmed in bunkers, at $11.50 per ton of 2240 lb. at either Cristobal or Balboa. For ships not in transit through the canal, $11.50 at Cristobal and $13.50 per ton at Balboa. For ships taking less than carload lots from plants or less than 25 tons from lighters, the price is $13 per ton at Cristobal, $15 at Balboa.

ANTHRACITE SHIPMENTS FOR MAY, 1919

The shipments of anthracite for May, as reported to the Anthracite Bureau of Information, amounted to 5,711,915 gross tons, as compared with 5,224,715 tons in April and with 6,887,256 tons in May, 1918. The increase of nearly 500,000 tons over April is gratifying, for it was accomplished in spite of the fact that most of the mines were shut down on Ascension Day and Memorial Day. The decrease as compared with May, 1918, was chiefly in steam sizes as, because of the war demands a year ago, washery tonnage was an important factor, whereas comparatively little washery coal was shipped last month.

The shipments by companies were as follows:

	May, 1919	May, 1918	Coal Year, 1919–1920	Coal Year 1918–1919
P. & R. Ry	1,156,119	1,356,878	2,200,311	2,590,390

MOVEMENT OF ILLINOIS, INDIANA AND LAKE DOCK COAL

The movement of bituminous coal from Illinois, Indiana and the Upper Lake docks into the northwestern states in 1917, with preliminary estimates for 1918, indicate the effect of the zone system on the movement of coal in 1918. This statement is given below because of the present demand for these statistics, in advance of the publication of the final reports of the Geological Survey for 1917 and 1918, now in process of completion. The tabulation is compiled by C. E. Lesher, of the Geological Survey.

	1917			1918		
From	Illinois	Indiana	Lake Docks	Illinois	Indiana	Lake Docks
Iowa	4,026,000	247,000	271,560	3,597,000	90,000	225,000
Wisconsin	1,936,000	564,000	4,484,768	2,486,000	617,000	4,870,000
Minnesota	1,801,000	199,000	4,151,132	1,968,000	28,000	4,565,000
North Dakota	43,000	3,000	618,131	8,000	200	654,000
South Dakota	231,000	15,000	477,961	228,000	500	610,000

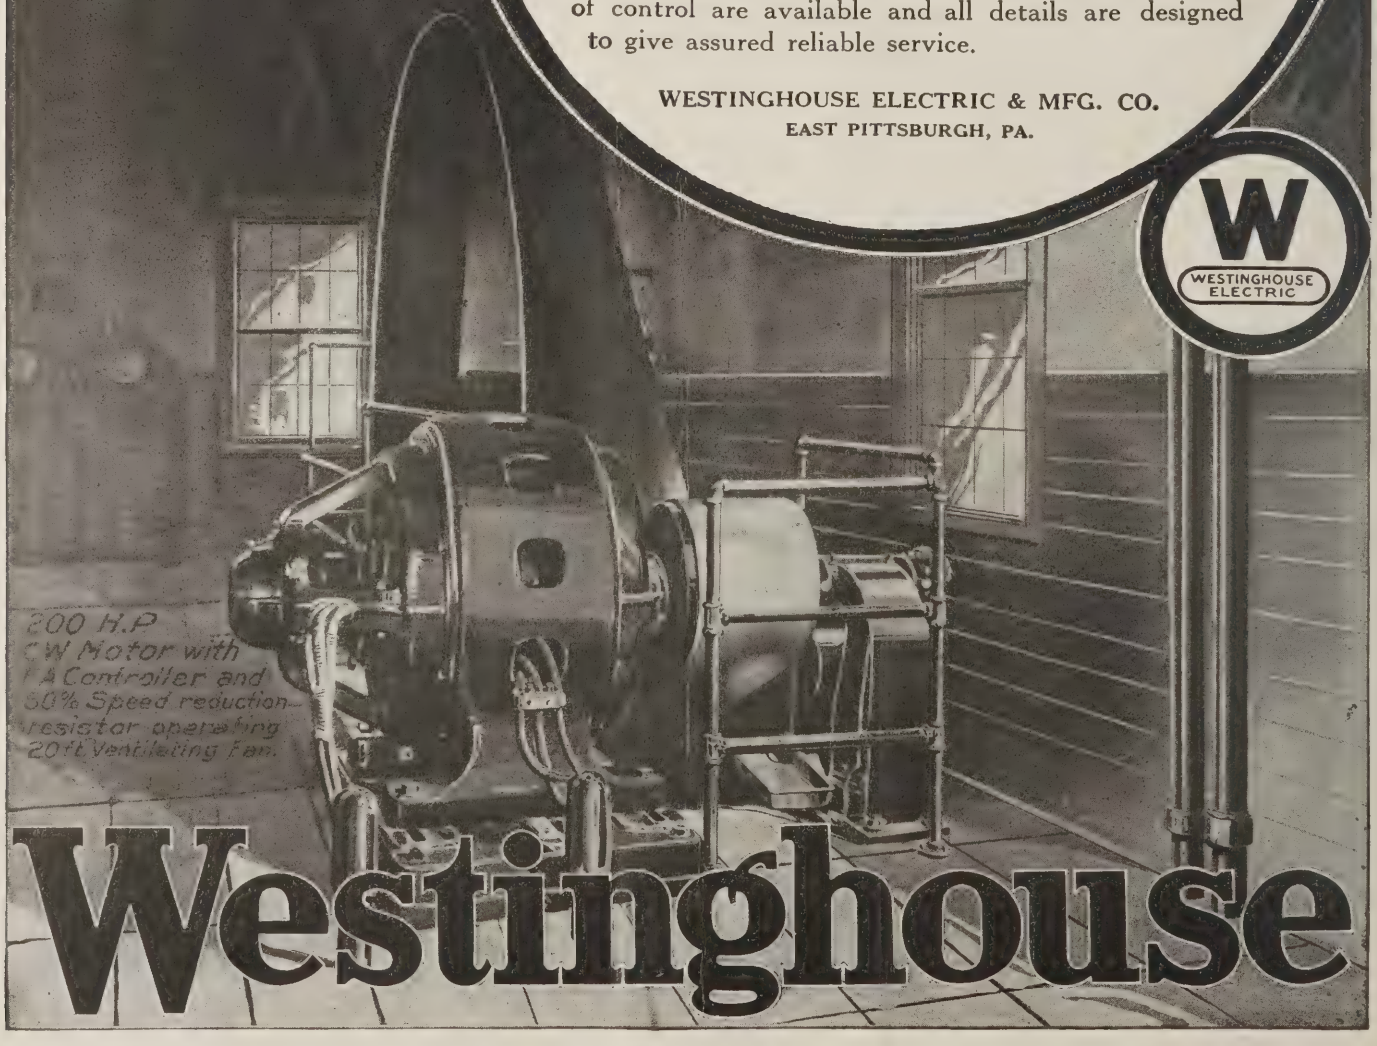
Where Reliability Counts

— The "Lungs" of the Mine —



Making a mine "breathe" properly is a prime requisite for uninterrupted production. Breakdowns in ventilating equipment that endanger life and hold up operations are too costly and obstructive; and for this duty—*where reliability counts*—Westinghouse Mine Fan Motors are the safest and soundest investment.

Westinghouse Motors for Mine Fans

are constructed to operate steadily—day after day. They are rugged mechanically and possess liberal size bearings. Form wound coils thoroughly insulated, assure continuous operation. These motors are available for alternating current or direct current systems, and can be furnished in either constant speed or adjustable speed types. Various forms of control are available and all details are designed to give assured reliable service.

*ILLUSTRATED

Foreword—New Tools Require New Training 1149
By R. Dawson Hall.

***The Chemistry and Constitution of Coal** 1150
By A. C. Fieldner.
Recounts How the Microscope has been brought into use to determine the composition of coal. Different coal beds appear to be built up of totally different varieties of plants.
Coal Age, June 26, 1919.

Some Common Violations of the Mining Laws 1159
Chief of the Mining Department of West Virginia, W. J. Heatherman, enumerates some of the reasons for the more frequent accidents in coal mines.
Coal Age, June 26, 1919.

Underground Motor Repair Shop 1161
By Ralph Mayer.
Coal Age, June 26, 1919.

***The Plastic-Arc System of Welding** 1162
By J. O. Smith.
Describes the Welding Process used in repairing the engines and other parts of the German ships interned at Hoboken. The process has its application in coal-mining.
Coal Age, June 26, 1919.

Tenth Annual Meeting of the Mine Inspectors' Institute 1166

The Importance of Rail Bonding 1167
By E. Steck.
Locomotives Often Fail through improper or inadequate electrical supply lines. The welded terminal type of track bond seems to give better results than other types.
Coal Age, June 26, 1919.

The EDISON Is the STANDARD Electric Mine Lamp

Its record has made the EDISON the standard electric mine lamp. Today, many thousands are in use, every one giving good service.

The EDISON has never been replaced by any other make of electric lamp.

EDISON Mine Lamp Batteries have the same rugged strength as the EDISON Batteries used in mine locomotives.

Ask for Catalog 300-C and details.

Installed at Chicago, Wilmington & Franklin Coal Co., Herrin, Ill.
Normal capacity 200,000 cu.ft. 3-in. water gauge, 170 r.p.m. Ten-foot Double Inlet Primarily Blowing Reversible Fan fitted with complete steel side drifts, all steel doors and steel hood extending over air shaft fitted with explosion cover.

Four Economies Travel Hand-in-Hand with a Jeffrey Stepped Multi-Bladed Type of Fan

1 **Economy of Operation**—The daily saving of power with every Jeffrey Mine Fan of average capacity is fully 20 per cent. This means a reduction of at least $1000.00 yearly in operating costs.

2 **Economy of Installation**—The complete steel casing extending to the ground line eliminates masonry, saves time, trouble and expense to install.

3 **Economy of Attendance**—Insured by double ring oiling, dustproof dynamo bearings, requiring attention only once every two or three weeks.

4 **Economy of Design**—Almost every mine has a different characteristic. Jeffrey Stepped Multi-Bladed Fans are designed to meet every condition found in the field of mine ventilation. The wheels are proportioned to meet high and low pressures, the casings are designed for economic installation at drift, slope or shaft mines.

These are a few of the reasons why Jeffrey Fans have been installed in every mining field. But you will want to hear the others explained in our Fan Bulletins. Write for copies.

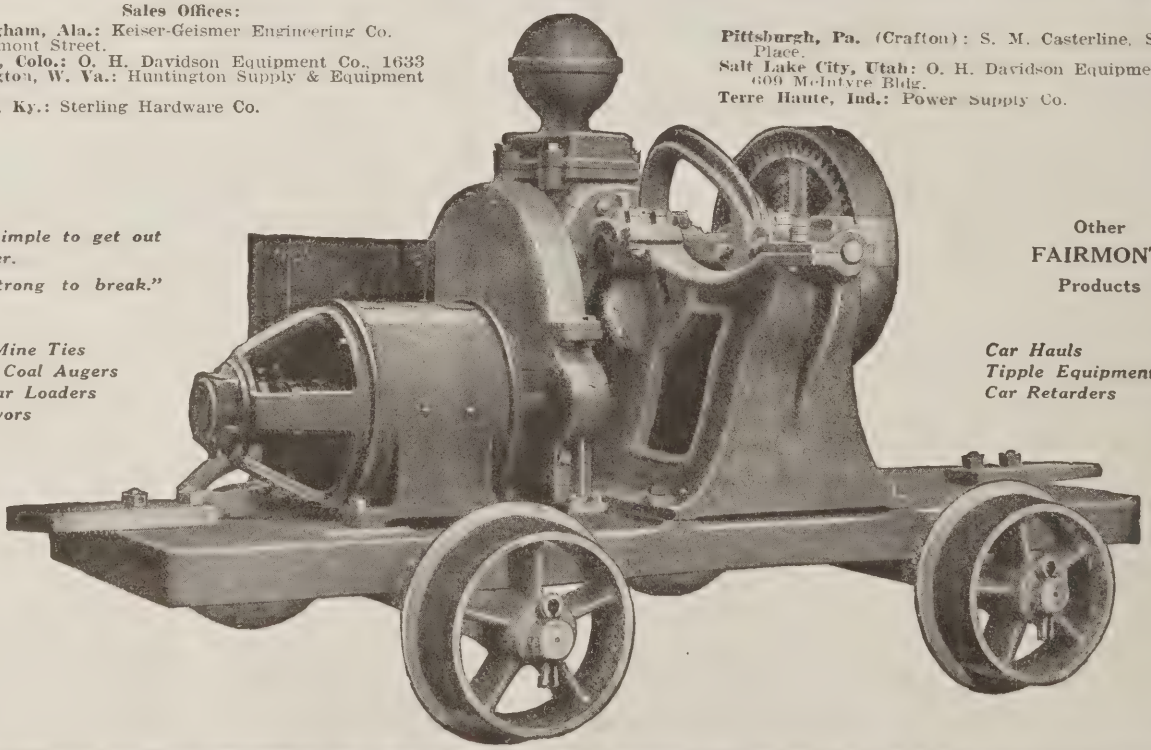
This Would Not Have Happened

had there been a FAIRMONT RUNABOUT ELECTRIC MINE PUMP on the job. The Fairmont Pump is so readily portable, so quickly connected up and such a dependable piece of equipment that seldom is a place drowned out in a Fairmont equipped mine.



The pump has so many good qualities they cannot be properly presented here. Our bulletins tell you all about the pump and why it stands up so well under trying conditions. You should have this bulletin.

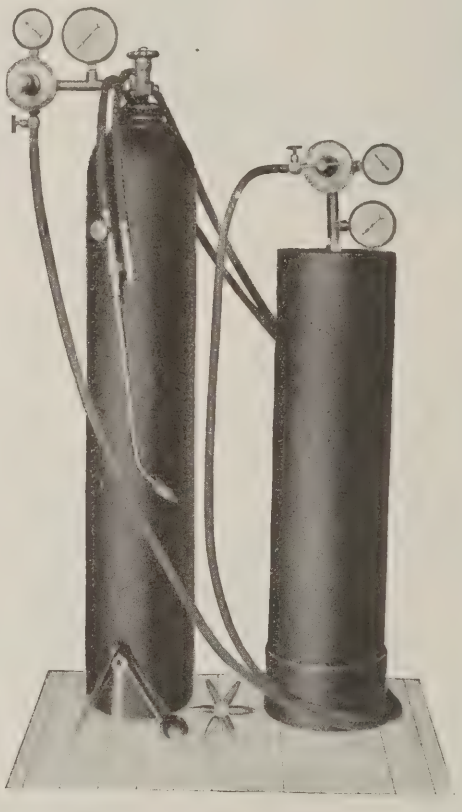
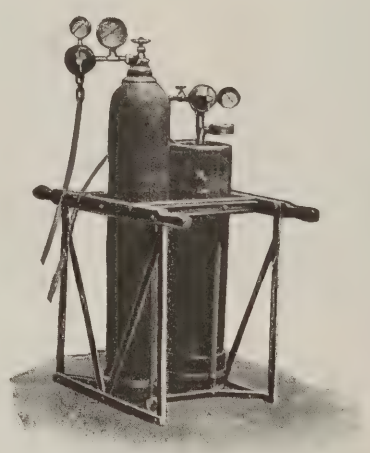
Complete Stock of Prest-O-Lite Equipment Carried at O-B Plant

During the war the art of welding progressed by leaps and bounds. Welding kept valuable parts out of the junk heap—saved invaluable time by emergency repairs—speeded up work of infinite variety.



We have taken the agency for all Prest-O-Lite welding and cutting equipment and supplies—except gas.

A complete stock of apparatus, parts and accessories is ready for immediate shipment out of Mansfield. The gas—which we do not handle—can now be obtained promptly.



Write for Prest-O-Lite catalog.

VULCAN

Safety For the "Man Trip"

The moment the signal is given for "man trip" a safe speed for the hoist is automatically set by the VULCAN Partial Speed Rig—independently of the operator who cannot increase the speed of the hoist until after the trip is completed.

The VULCAN Partial Speed Rig is only one of the safety features of VULCAN Hoists; there are thirty-three others.

Correspondence invited.

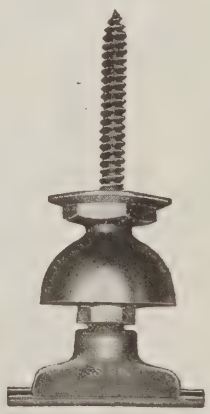
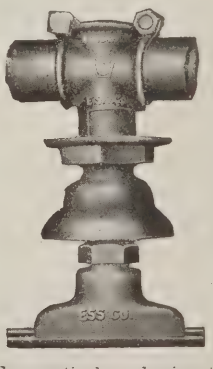
Keystone Trolley Material

FOR PERMANENCY

Keystone Trolley Material provides strong, durable, and moisture-proof construction. It is unaffected by the highest degree of atmospheric heat and is designed in accordance with latest practice. It is specially constructed for severe mine service. It is giving utmost satisfaction in hundreds of busy mines because of its high quality and permanency.



It provides a wide variety of combinations to meet every condition. Right now, you should be using it. Write for data sheets.



For vertical or horizontal pipe construction.

For installation in top.

For installation in timber.

For vertical or horizontal pipe construction.

KEYSTONE LUBRICANTS

Keep It Coming!

EVEN though the armistice has been signed—despite the fact that the actual fighting has ceased — coal is badly needed. Production must be kept up to meet present demands—and the demands to follow!

Keystone Grease for Mine Car Wheels is an important factor in increasing mine efficiency and decreasing fire risk in the leading coal fields of America. It lengthens the life of rolling stock, saves time, labor and money—and *speeds up* production. Its density is unaffected by temperature changes, water, or outside chemical attacks—and one application insures perfect lubrication for from three to six months.

There's a special Keystone Density, scientifically suited for every type of mine car wheel. Keystone Grease No. 119 Medium should be used for Hyatt Roller Bearing Wheels, Keystone Grease No. 119 is suitable for wheels of all other types.

UNIVERSALLY KNOWN UNIVERSALLY USED

JEFFERSON

"Look for the Name on the Nut"

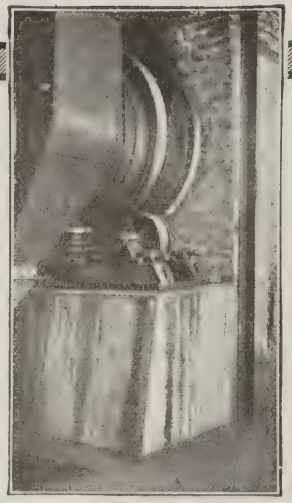
JEFFERSON UNIONS are particularly adapted to the requirements of underground pump service. The Brass Seat Ring makes a tight brass-to-iron joint which cannot corrode, and is easily disconnected. The Spherical Ground Joint takes care of alignment difficulties and makes possible a tight joint even if the line is not exactly straight.

And there are other important reasons why JEFFERSONS are better. "The Name on the Nut" protects you against substitute "just-as-good" unions. You would have a mighty hard time trying to make tight a leaky union with a "just-as-good" promise.

Ask your Jobber and JEFFERSONS. He knows every union that's made and can tell you just hy JEFFERSONS are better. Write TODAY for our Catalog "UNIONS"

The Jefferson Union Co.
Lexington, Mass.

GOODRICH



"LONGLIFE"
CONVEYOR BELT

TROUGHS of its OWN WEIGHT

Goodrich De Luxe Truck Tires ride easier; wear longer; run faster without damage to tire and truck; save engine power and fuel.

"LONGLIFE" spells economy in every detail of its construction. Once properly installed the man in charge can feel satisfied there will be no mechanical or labor charges placed against the operating cost of "LONGLIFE."

INGERSOLL-RAND

"IMPERIAL" TYPE "XPV" COMPRESSORS

Built to meet the need for a steam driven unit to deliver from 608 to 4219 cu. feet of air at pressures to 110 lbs. per sq. in.

STEAM ECONOMY IS ITS OUTSTANDING FEATURE

Balanced piston steam valves and automatic cut-off control permit the attainment of a remarkably low rate of steam consumption. This means lower boiler horse power needed and money in the owner's pocket. Their design also permits the use of high steam pressures and superheat—no valve warping and leakage—perfect balance minimizes the valve driving power requirement and facilitates lubrication. Steam valve chests have easily and inexpensively renewable bushings.

"We Want You to Become Better Acquainted With Us" Series. Number 8-F

NO. 2 MEDIUM WEIGHT
SLICK STEEL MINE TIE

Simplicity is an important feature. This is the friction button which securely holds the rail in place and cannot be lost.

2½ Inches headroom, gained by the use of the Slick Steel Mine Tie in place of standard wooden tie.

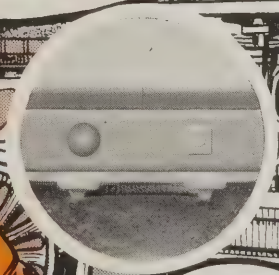
A quarter turn of the friction button with this wrench fastens the rail in place. No lost motion. A big saving in time.

Lincoln Dynamotor

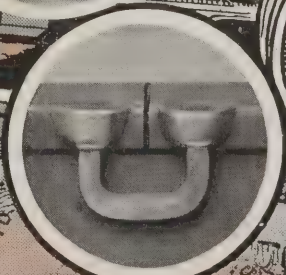
Portable Bonder and Welder

The Lincoln Dynamotor will also Repair Worn and Broken Car Equipment

Permanent Bonds Quickly installed



Even an unskilled man can easily and quickly install Lincoln Bonds with the Lincoln Dynamotor, but it would take a sledge-hammer and hard slogging to break them off.

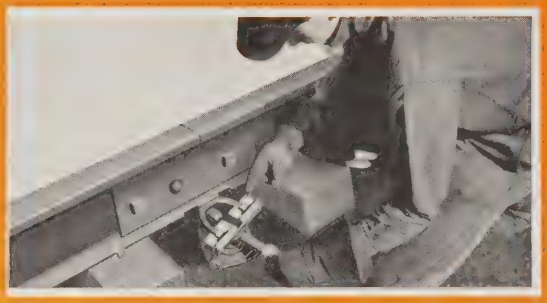


The carbon arc process used in the Lincoln Bonding System insures **every strand** being thoroughly welded to the rail.

Lincoln Bonds **stay put.**

The Lincoln Bonding Co.

CLEVELAND, OHIO

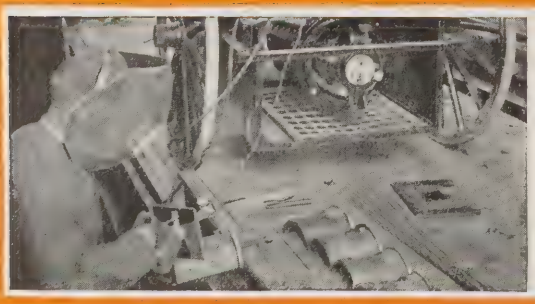


The Lincoln *Welded* Rail Bond is Quickly and Permanently attached to the Rail

OVER

Rail Bonding under Traffic

WITH THE LINCOLN DYNAMOTOR



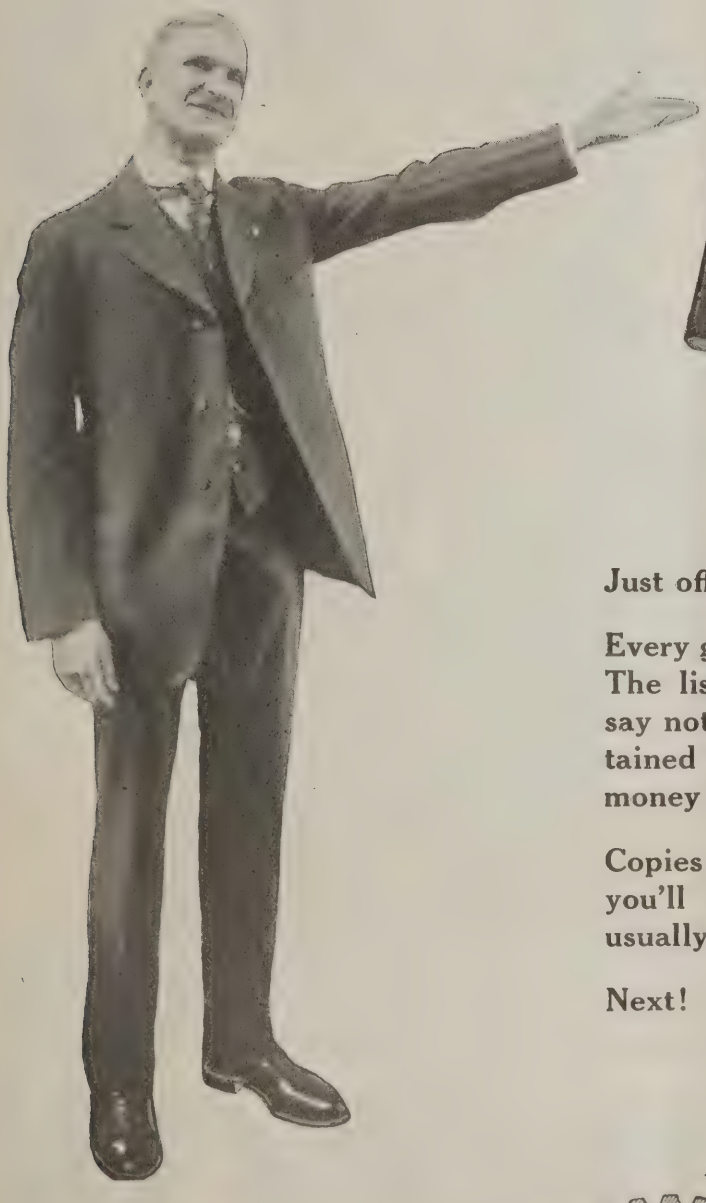
So short is the time required for welding a Lincoln Bond to the rails that coal hauling can be maintained without interruption. These photos show the method of installation.

Cars Have Just Passed. The welder places the mold holder which holds the carbon mold containing the Lincoln Bond in position under the rail, two notches having been previously cut with the arc from the bottom flange of the rail to accommodate the bond heads.

45 Seconds Later. The welding operator has welded the bond solidly to the rail by means of the carbon arc generated by the Lincoln Dynamotor. The carbon mold retains the molten metal, thus building up the head of the bond and welding it to the under side of the rail.

The Bond is Now Installed. It only remains to pull out the mold holder from underneath the rail and the trolley pole from the wire and the track is cleared.

Let us speed up your bonding and cut your resistance losses. Write us today for a demonstration of the Lincoln Dynamotor and Lincoln Bonds.



The Lincoln Dynamotor gives you a perfectly continuous and permanently welded track—it is a motor and generator in one which will do every kind of welding repair you have about the mine. Pay for it out of what it saves from your scrap heap.

Deane Works
Holyoke, Mass.
Hazleton Works
Hazleton, Pa.

Another way Worthington machinery showed its patriotism

It carried overloads in making soldiers' clothing

WHEN the pressure of war called for uninterrupted service, Worthington equipment everywhere responded. As, for example, in the making of wearing apparel for the doughboy.

Practically everything he wore at one or more stages of its development was affected by Worthington equipment. In Lawrence, Massachusetts, for instance, Worthington Pumps lent a hand in making production records of fabrics; in a neighboring factory Worthington products played a part in making shoes worth millions; while in various other places Worthington products did their prosaic bit in the manufacture of shirts, raincoats and hats.

In the ability of Worthington equipment to meet overloads—as well as in the ability of the eight great Worthington factories to meet emergencies—lies a sure indication of what Worthington will mean in the after-war reconstruction.

Blasting Supplies

that are dependable

In all work calling for the use of explosives, it is extremely important that the accessories known as Blasting Supplies shall be of the very highest quality. Defective or weak detonating devices often imperil both life and property—and result in a loss of explosive energy, if no more.

In the manufacture of Atlas Blasting Supplies the most scrupulous care is exercised to make them thoroughly practical, effective and RELIABLE. The ATLAS name on detonators, galvanometers, rheostats, blasting machines and other blasting supplies signifies that they are as safe and sure as it is possible for experience and manufacturing skill to make them.

Our Service Division will gladly confer with you as to what detonating supplies will give you the most economical service.

PLYMOUTH

Gasoline Locomotives

"PLYMOUTH" *Has Cut Mule-Hauling Costs Squarely in Half*

Nut-shell testimony from users of experience — the Southern Connellsville Co., Uniontown, Pa., who wrote about their PLYMOUTH'S good work after using it for nearly a year.

This Locomotive has entirely replaced horses and mules in the company's hauling, both above ground and down in the mines, and General Manager S. A. Carson tells us that—

1—Operating cost is just half that of horses and mules.

2—Doesn't require skilled operator. Uses only 5 gallons gasoline and 1 quart lubricating oil daily.

3—Average load, 8 cars, 50 bushels each. Locomotive easily makes round trip—more than 1½ miles—3 to 4 times an hour.

4—No fumes in mine; performance strictly O. K.

5—PLYMOUTH Friction Drive is efficient, durable, trouble-proof.

Tell us about *your* hauling. Full particulars gladly sent you.

LOOKING AHEAD

Each week Coal Age is reaching a large percentage of the more progressive coal mine executives in this country. The coal mining industry is becoming more active each day. The railroads are beginning to purchase their contract coal and the other industries will soon follow. Every indication points to the fact that late summer and fall will see great activity in this field. This means the buying of vast quantities of equipment and supplies. Are you getting your share of the business this field offers you? Coal Age will place the merits of your products before the men who have the authority to buy. Now is the time to reach them.

COAL AGE

10th Ave. at 36th St., New York, N. Y.

To determine the value of any switchboard compare the service it gives with that of the ideal board

What do these facts mean to you?

The primary requirements of the ideal switchboard are uninterrupted service and personal safety at all times. A high standard of switchboard design and construction is indicated when interruptions can be made merely a matter of minutes, when personal safety is afforded at all times, when installation costs are low and when inspection is both easy and safe.

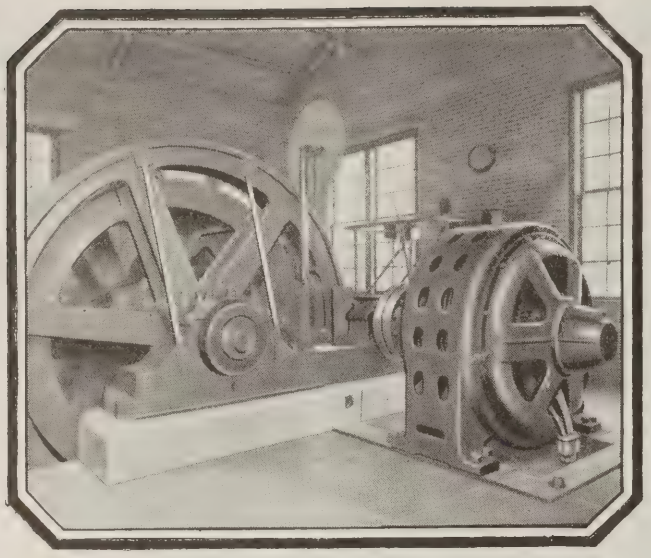
Safety at all times—Personal safety and reduced fire risk are afforded by complete enclosure of all live current-carrying parts within the steel compartment, illustrated.

Interruptions, few and short—With a spare truck of proper capacity, it is a matter of minutes to substitute for a panel in case of trouble and to maintain practically continuous service.

Simplifies extensions—Panels can be added to or taken from an existing switchboard quickly and easily.

Low installation costs—Each assembled unit is complete, thus making installation merely a matter of bolting into place and connecting electrically.

Inspection, easy and safe—All instruments, switching and protective devices, are mounted on a truck which can be withdrawn only when its equipment is dead, electrically.



Consult the G-E Switchboard Specialist in your vicinity. Write our nearest office.

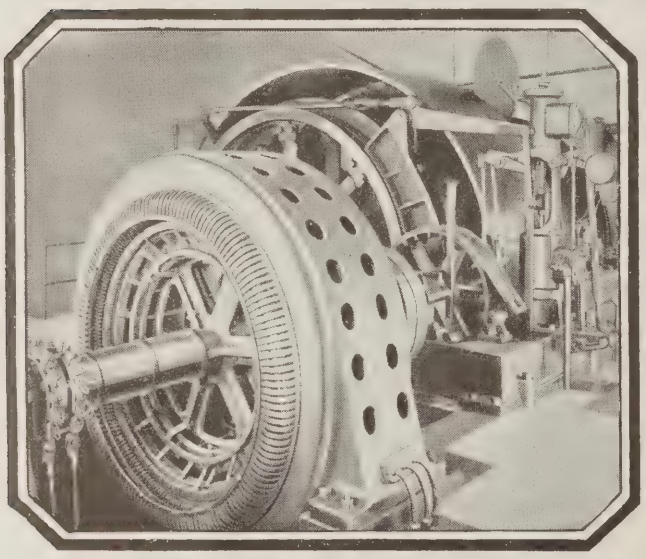
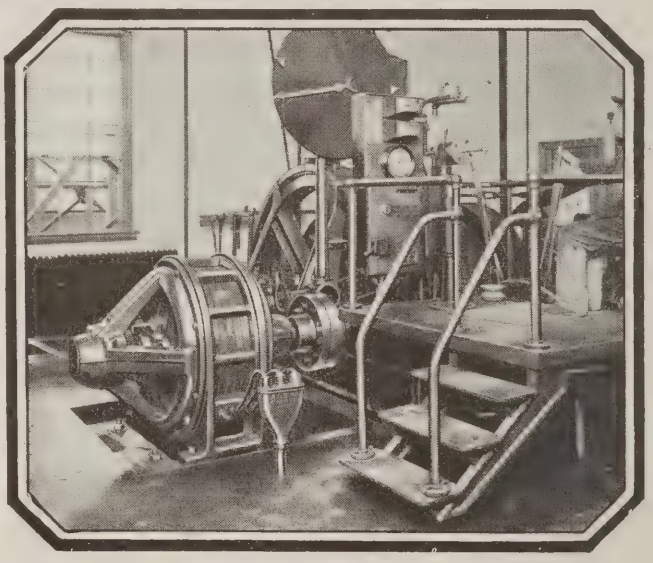
600 h.p. Motor driving Hoist



600 h.p. Motor driving Slope Hoist

More Coal Hoisted—Less Burned for Power



Eight times as much coal is often burned to supply steam to a small steam hoist as would be necessary to supply steam, in an efficient central power station, for the generation of electric power to operate the same hoist.

Piling up of cars at the foot of the hoist is almost unknown where electric hoists are used. The steady pull of the electric hoist greatly reduces the possibility of delays due to general upkeep, repairing ropes, shaft guides, etc.

Hoist operators are universally proud of their electric hoists and anxious to have them make a fine tonnage record.

OFFICIAL PROPOSALS

Bids: July 23.

Coal Crusher and Coal Drying Equipment

LIGNITE UTILIZATION BOARD OF CANADA
CREATED BY THE DOMINION GOVERNMENT
BY ORDER IN COUNCIL
80 S. FRANCOIS XAVIER ST.
Montreal, P. Q.

The above Board will receive tenders for a coal crusher until 12 o'clock noon, July 23rd, 1919, and for coal drying equipment until 12 o'clock noon, July 30th, 1919.

Specifications and full information may be obtained upon application to the Secretary of the Board. A charge of $2.00 each will be made for copies of specifications, which sum will be refunded to bona fide tenderers or upon the return of the specifications.

The Board does not bind itself to accept the lowest or any tender.

R. A. ROSS,
Chairman.
LESLIE R. THOMSON,
Secretary.

FOR SALE

Complete Mine Outfit For Sale

Three tracks tipple, scale, screens, pans, Hopper, bolted together, one Dinkey engine, mine car, 16 lb. relay, 60 lb. relay, two iron, blacksmith shop, gas engine and fan. H. M. Hoover, Middleport, Ohio.

WANTED

We are anxious to purchase at once the following equipment

COAL HOISTS

Five coal hoists 10 x 12 Meade-Morrison Tandem drums with a boiler 54 in. x 10 ft. or 60 in. x 60 in. vertical Mass. Standard. Also one 36 in. x 7 ft. Mass. Standard boiler.

HOISTING ENGINES

Six 2 and 3 drum 10 x 12 standard make of hoisting engines with Mass. standard boilers, 10 h.p. to 20 h.p. 220 volts direct connected. One and two drum electric hoists. 75 and 100 h.p. electric hoists. 500 volts A.C. 3 phase 60 cycle.

MOTOR CRANES

One 40 ton 3 motor crane, 220 volts, A.C. one 20 tons 3 motor crane, 220 volts, A.C. 40 ft. span between centres.
1—10 ton, 3 motor crane, 500 volts, A.C. 100 ft., 6 in. span.

GANTRY CRANES

5-5 ton gantry cranes

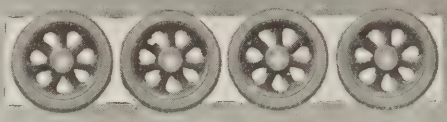
"Built to Dig and Last While Digging"



Lowering Production Costs

Williams Buckets are enabling coal men everywhere to handle larger quantities with less labor in less time than with obsolete handling methods.

They were installed primarily to speed up production. Now their fortunate owners find upon analyses that they are unit cost reducers as well. Let us show you how we have reduced handling costs for others and how much you can lower yours.

Write for catalog.

LOBDELL
Mine Car and Locomotive Wheels

are not merely a matter of good intentions.

Every wheel maker has good intentions to make his wheels the best.

Other wheelmakers, doubtless, use as good materials—none better. Some may have as skillful workmen.

But granting these things the LOBDELL CAR WHEEL COMPANY still has what no other wheelmaker can claim—EIGHTY YEARS OF "KNOWING HOW."

We claim on account of this experience the right to say that "LOBDELL wheels are the standard by which all others are judged."

"The proof of the pudding is in the eating"—you will have to do that in your own mines.

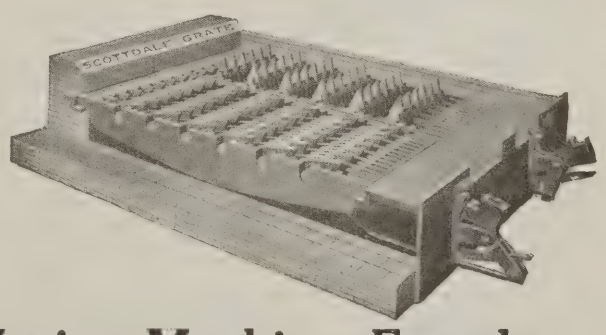
Miners' Safety Squibs

for Coal and Rock Blasting With Profit to Miner and Operator

Miners' Supply Co.
St. Clair, Pa.

MARION MACHINE, FOUNDRY & SUPPLY CO. MARION, IND.



Marion Products Represent Peace Time Economy

THERE is assurance of real economy in the purchase of Scottdale Crushers. Our engineers spent years developing a crusher best designed to meet the requirements of coal yards and power plants where fuel economy is maintained to a high degree. They are sturdy, simple and versatile. Built in capacities of from 20 to 240 tons per hour, there is a Scottdale for every requirement. Send for bulletins.

SCOTTDALE GRATES represent the logical step from the ordinary grate. Nothing but fine ash escapes. The fire is controlled from the outside, eliminating constant opening of fire doors. A gentle agitation of the grates without opening the distance between the bars will brighten up the fires. When clinkers are to be dumped, the illustration shows the simplicity and efficiency of the operation.

Quality metal eliminating warping evils, heavy duty construction insuring long and severe service, accuracy of its controlling levers, adaptability to coking, spreading or alternate spreading methods of firing are points of superiority most vital in a fuel saving grate. They have brought Marion Scottdale Grates universal praise. Send for particulars.

The 10-Spoke Wheel Doubles the Life of the Sterling Wheelbarrow

With a better and stronger wheel—reinforced by two extra spokes—the Sterling Wheelbarrow now will actually last twice as long as formerly.

By adding the two extra spokes—making ten instead of the usual eight—the segments between spokes are shortened, thus adding both strength and length of life to the already strong and long-lived Sterling barrow. As usual, Sterling is first in the field with this new idea.

A Catalog? Certainly. At your request, we'll gladly send it.

Jenkins Valves

"They're Reliable"

an engineer said when asked why he used Jenkins valves. "When we close a Jenkins valve on a high pressure steam line, it **stays closed** and when we open it there's no sticking at the seat. And in the case of their gate valves the wedge is easily raised or lowered and allows an unobstructed passage—it never "drags" across the seat and fits **tight** when closed."
For high pressure steam service Jenkins Valves are made in Globe, Angle, Cross, Check, Y or Blow-off, Automatic Equalizing Stop and Check and Gate patterns.

Illustrated is a battery of Jenkins valves on steam pressure duty atop the boilers of a New Jersey power plant
Jenkins valves are the result of fifty years of practical experience in making valves as they should be made for each specific use—Know them by the Jenkins "Diamond Mark."

GUNITE

Is Far Stronger Than Concrete

Compressive Strength

Sample		Strength		Modulus of Elasticity
A	—	4640	—	4,750,000
B	—	3125	—	.....
C	—	3540	—	4,750,000
D	—	4980	—	3,890,000
E	—	4385	—	.....
F	—	4145	—	3,500,000
G	—	4200	—	4,500,000
Average		***4145*** Lb./sq.in.		***4,278,000*** Lb./sq.in.

ACTUAL tests by the Bureau of Standards, Washington, D. C., prove conclusively the remarkable strength of GUNITE, the cement-sand product of the

CEMENT-GUN

Among concrete engineers "2000 lb." concrete has long been standard. Note that GUNITE *averages more than twice as strong* as "standard concrete."

The reason for the unusual strength of Gunite is found in its *scientific* mixing and application. The cement and sand are mixed *dry*, hydrated at the nozzle and *shot* out so forcibly by compressed air that the mixture is actually *hammered* into place.

Other tests prove that GUNITE is far superior in tensile strength and adhesion as compared with "standard concrete."

Interesting Bulletins giving scientific data on GUNITE under laboratory, weather and fire tests will be mailed on request. Write TODAY.

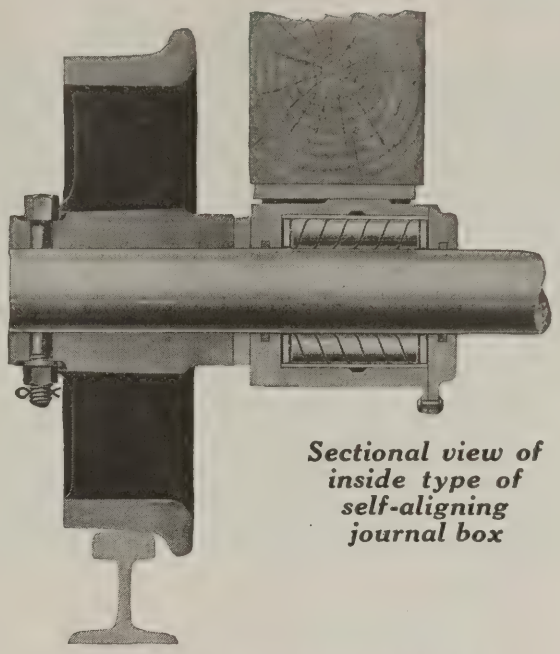
Lower the Friction Loss of Your Mine Cars

OTTUMWA
Roller Bearing Car Wheels

will lessen friction and the consequent wear They operate with 50% less power and only require greasing once or twice a year. Made of carefully selected tough iron.

If you will write us the weight of car loaded, track gauge, wheel diameter and distance from center to center of axles—we'll quote prices.

Ottumwa Iron Works, Ottumwa, Iowa



The Open Cap Truck
(Guaranteed)

IN this Truck are combined all the essentials that go to make up a first-class Mine Car Truck. It can be lubricated with either grease or oil with long service from each lubrication—is thoroughly dustproof—runs with very little friction—has a full-floating axle with visible linch pins which can be easily replaced, and is guaranteed against internal wear.

Selected by the Atlantic Refining Co. to demonstrate, at the American Mining Congress in Philadelphia, the highest development of a self-oiling wheel using their lubricant. We'll send you details.

Phillips Mine and Mill Supply Co.
Pittsburgh Penna.

Sectional view of inside type of self-aligning journal box

PROHIBITION

of excessive haulage costs has caused many successful coal operators to buy our FLEMING-HYATT self-aligning roller bearing journal boxes.

They bought them because they knew that they would save "worlds of power and lubricant" literally speaking and they would have been perfectly contented if our boxes had done that and nothing more.

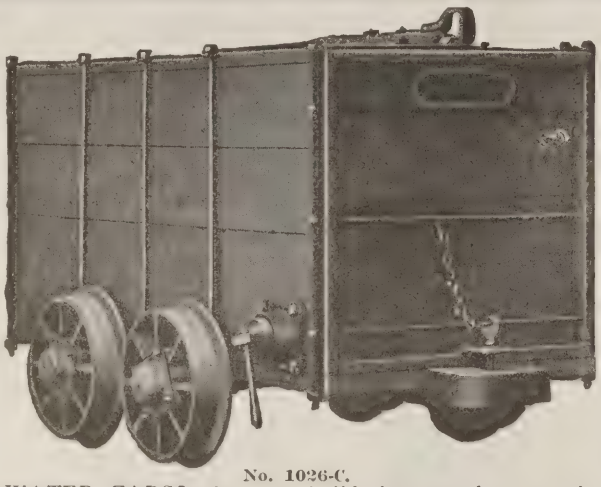
But because we have been building journal boxes for mine cars for the past twenty-five years we know that they should have something else, so we built them so that they were self-aligning, just like railroad journal boxes.

The self-aligning (or ball and socket) principle takes all of the strain of the running gear of the car and greatly relieves the strains that tear the body of a car to pieces.

In addition there is just enough play to compensate for the low spots in the track and the "give" of the boxes also helps the cars to round the curves without the tremendous waste of power wherever the rigid types of trucks are used. You, as an engineer, will also appreciate that your trackage will be greatly benefited.

An engineer who is opening up a big mine equipped it with big six-ton cars with rigid running gear. He saw one of our boxes the other day and he said, "If I had known of your boxes when I bought my cars I certainly would have put them under my cars."

He was a man with railroad experience and he knew that every heavy car should have self-aligning boxes; like ours under them. We believe we will sell him hundreds of our boxes.



There is no need for you to go any longer with your rigid truck equipment for our FLEMING-HYATT boxes can be applied to almost any car. No matter whether inside wheels or outside wheels; 6 in. x 8 in. sill construction or flat wood or steel bottoms, we can fit our boxes to your cars.

You can still use your present wheels and the time and trouble necessary to make the change is small compared to the many advantages you would gain from their use. They are the ideal equipment for heavy mine cars but work just as nicely under the smaller cars.

Please write us today! No obligation on your part now, but you will feel obligated to us when you know how well we have solved your truck problems.

D.C. TURBO GENERATORS

Direct current is preferable for hauling and for the operation of coal cutters and other tools. The most simple, direct, and inexpensive way of producing it is by means of a direct-current generator driven by a De Laval Steam Turbine, using a double-helical speed-reducing gear to permit the turbine to run at the best speed for efficiency. Losses in transformers and rotary converters and complications of equipment are thus avoided.

De Laval Steam Turbines, with or without Gears, also constitute the most economical drive for centrifugal pumps and fans. Each De Laval unit is fully guaranteed as to capacity and efficiency and is thoroughly tested before shipment.

DE LAVAL STEAM TURBINE CO., TRENTON, N. J. 52

The

Harris

10-Inch Stroke

Wood Lined

Triplex Mine Pump

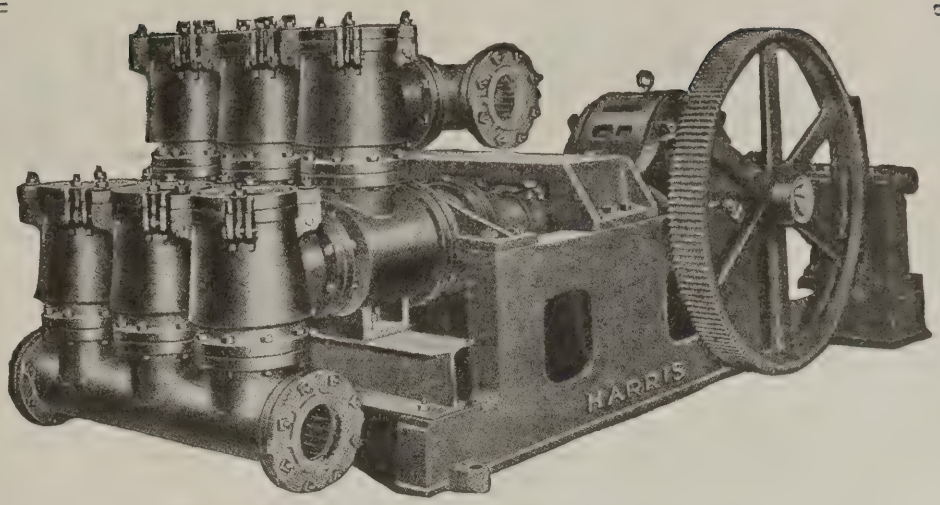

Figure 74. Capacity 300 to 500 gallons per minute.

SOME FEATURES

Connecting Rods are of very massive construction and have split bronze boxes at both ends with wedge and screw adjustment.

Cylinders are cast separately and bolted to the valve pots and to the stuffing box head. **They are lined throughout with wood.** All cylinders are exact duplicates.

Valve Pots are cast separately and bolted to the cylinders and to the suction on discharge yokes. **They are lined throughout with wood.** All valve pots are exact duplicates.

Valves are of special reinforced rubber and so constructed that they positively cannot warp and are guaranteed to outlive any other type of valve.

Self-contained fire pump unit for plant protection

The Lea-Courtenay Centrifugal Fire Pump has been accepted by all insurance boards.

LEA-COURTENAY CENTRIFUGAL PUMP

Lea-Courtenay Centrifugal Fire Pumps are built on insurance standards; in capacities of 500, 750, 1,000 and 1,500 GPM., to be operated by gasoline engine, steam turbine or electric motor; singly or in combination for emergency.

The first successful self-contained fire pump equipment was a Lea-Courtenay centrifugal pump coupled to a gasoline engine. One of the many distinct advantages of a pump of this type is there is no stand by charge for electrical current; neither does it rely on the city electric light plant for its power.

Deming

PUMPS THE WORLD'S BEST

HAND AND POWER PUMPS FOR ALL USES

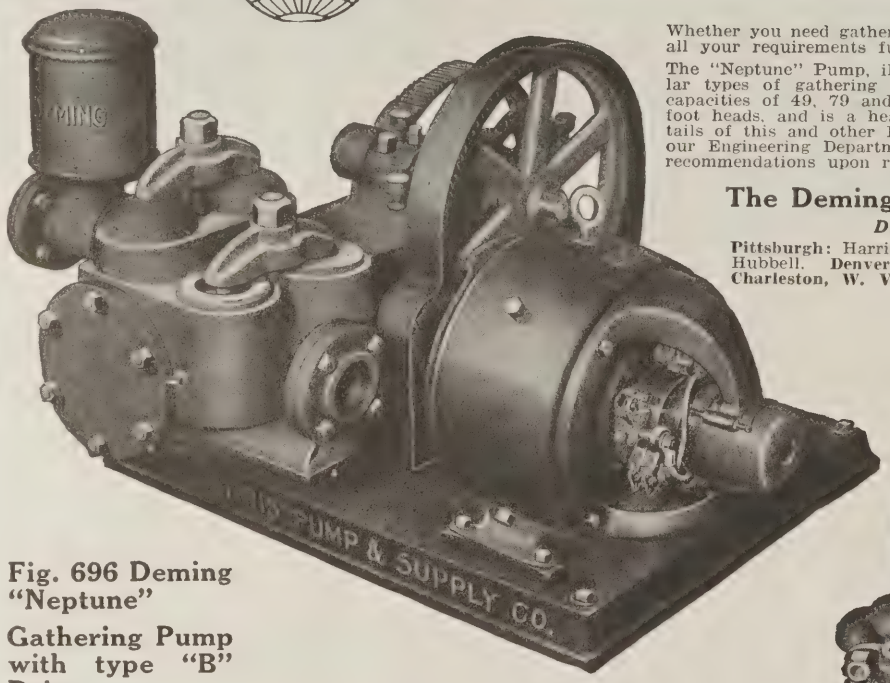

Fig. 696 Deming "Neptune" Gathering Pump with type "B" Drive

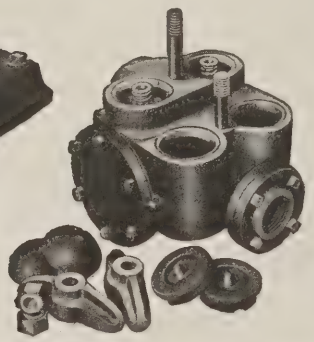

Whether you need gathering, sump or station pumps—you will find all your requirements fully covered by the Deming line.

The "Neptune" Pump, illustrated below, is one of our most popular types of gathering pumps. It is made in three sizes, with capacities of 49, 79 and 119 gallons per minute; is good for 150 foot heads, and is a heavily built, powerful pump. Complete details of this and other Deming Pumps will be sent on request, or our Engineering Department will be glad to submit estimates and recommendations upon receipt of information.

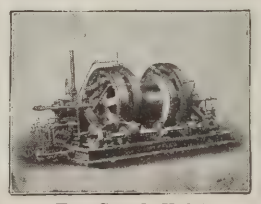
SIMPLICITY

— that's the fundamental characteristic of the Caldwell Friction Clutch. It has only eleven parts, it's built on exactly the same principle as your automobile brake and just as easy to operate — a flexible band lined with Raybestos, tightened with a lever and adjusted by a single screw.



The result is that breakages caused by complicated adjustments are impossible in a Caldwell Clutch.

For Greater Safety At the Mine, Use

TURBOGEAR

FAST PATENTS

Turbo Gear is the modern form of reduction drive—there are no exposed belts, pulleys, chains, sprockets, offset, spur or bevel gears. Turbo Gear consists of double helical herringbone gears revolving within a fixed internal gear; the whole being completely enclosed in a heavy iron housing. There can be no danger in Turbo Gear drive, for the only projecting moving parts are the smooth, round, high and low speed shafts.

Another very real advantage arising from this completely enclosed construction is the fact that it eliminates the necessity for attendance. As long as the oil well is filled Turbo Gear takes care of itself, and protects itself against damage.

Built in capacities from 1 to 20,000 horsepower, to handle speeds up to 6000 r.p.m. and to either step speed up or down; there is a Turbo Gear for every drive need.

"Made It All Right"

"I was at Springfield on the sixth of this month before the Mining Board to be examined for first-class mine manager, and made it all right. I give the credit to the Library of Coal Mining and Engineering," writes Peter Boland, 306 Prosperity Street, Carterville, Illinois.

THE above is one of many stories of success achieved through the assistance of the Library of Coal Mining and Engineering.

This Library will help you to reach the position in the coal mining field which you aspire to. There is no question about this.

It will enable you to master the practical side of colliery operation from surveying to handling the complete mechanical equipment of the mine.

It will enable you to suggest to the owner unquestionable and tried means of rectifying any mistakes in management. It will enable you to inaugurate these improvements and maintain them.

It will give you ideas and tell you how to carry them out, without the aid or advice of others.

Over three-thousand pages of the best of modern practice, indexed so that you can find what you want immediately—*and understand it when you find it.*

Let us send you the entire set of eight volumes weighing about fifteen pounds, to look over. No obligation on your part to keep the books.

McGraw-Hill Book Co., Inc.

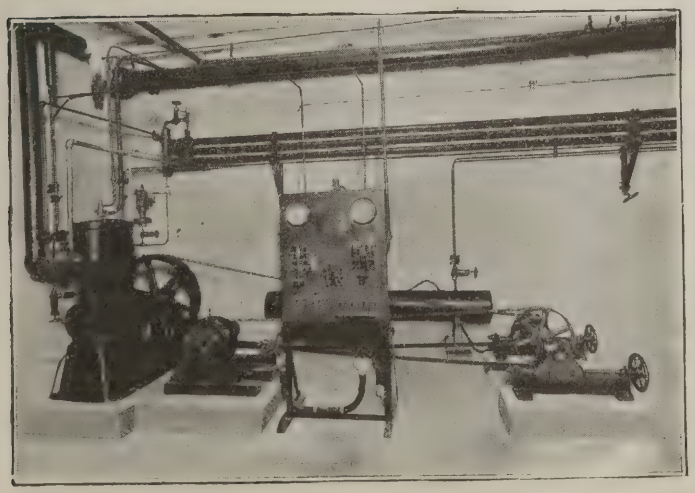
USUALLY, Bartlett and Snow Tipple Equipment costs more money. But why shouldn't it?



It costs more to build and less to run. It's stronger where strength is needed. It'll save you many a breakdown and a single breakdown avoided will save you a great deal of money.

When you buy Bartlett and Snow Tipple Equipment we want you to expect to get machinery that's better, stronger, more reliable. We want you to feel that it is going to produce clean, sized coal at a lower cost per ton.

WYCKOFF

WOOD PIPE

Instead of renewing your costly iron pipe—

Install Wyckoff Wood Pipe, the pipe that has been making good in mine service for the last half century.

Its faculty for resisting the action of sulphurous water is the reason for this—

Incidentally, it's the reason why Wyckoff Wood Pipe is in service in 90% of the Anthracite Mines and at least 60% of the Bituminous in the country.

So if you seek a pipe of proven durability, Wyckoff Wood pipe is that pipe—

As our engineers will prove to your satisfaction if you will take advantage of their cooperation.

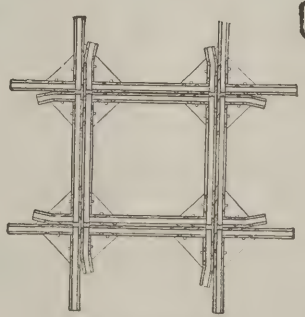
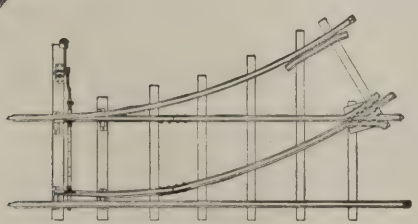
IT PAYS

Central Frog & Switch Company "TRACK EQUIPMENT" is far superior to the "home made" variety. Install **"CENTRAL"** Track Equipment, and avoid derailments, wrecks, and unnecessary delays.



Just the other day we booked an order for Light Rail Turnouts, consisting of Frogs, Switches and Stands, at a price which was 33⅓ per cent. less than it had been costing our customer to make them. We are **Track Specialists,** and pay particular attention to the manufacture of Light Rail Equipment for Coal Mines.



Curved Room Turnout

Spring Switch Stand

Riveted Crossing

Curved Room Turnout

Give us the gauge of your Track and weight of Rail which you are using, and we will quote prices. A trial order will convince you that **"CENTRAL"** Track Equipment pays big dividends.

Prompt shipments. Let us hear from you.

For Special Services

That there is a Diamond Belt for every purpose is exemplified by Diamond Special service Conveyor Belting. Extra heavy rubber covers are specially compounded to resist the action of every class of material for which the Conveyor Belt can be used in the Coal Industry. Hot ash, Coke, run-of-mine Coal—Acid and Alkaline products—for all your Conveyor requirements the duck and construction of the Diamond line of Belts is such as to best meet the hardest of Service requirements.

For Mine Telephones

Ironite

is the one rubber insulated twisted pair telephone wire that has the tensile strength, flexibility and toughness of insulation to successfully stand up under the strains and trying conditions of mine use.

Cheaper than hard drawn copper. More serviceable.

Write today for full information and sample.

Paragon Electric Co.

35 West Van Buren St., Chicago.

A DURABLE, dependable material for every wrought tubular requirement. Sizes ⅛ to 30 in. O. D., inclusive—Spellerized (sizes 4 in. and under) to reduce any tendency to corrosion—thoroughly inspected and tested.

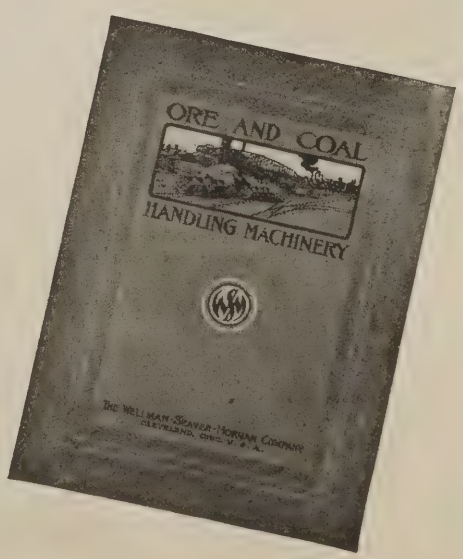
COAL OPERATORS



who are using Simplex Rivetless Chain operative on double flanged sprockets specify no other, as this driving principle has proven a saving of fully 20% over inside drive and riveted types. THERE'S A REASON. Write for details. Made 6 and 9-in. pitch.

CROSS ENGINEERING CO., Carbondale, Pa.

Modern Ore and Coal Handling Equipment

All those contemplating the erection of plants for the unloading, conveying or storage of ore, coal or other loose materials—also those now operating such plants—will be interested in having a copy of our 100 page catalog illustrated at the right. A copy will be sent to you on request.

THE WELLMAN-SEAVER-MORGAN COMPANY
Cleveland, Ohio.

Some Views of the Virginia Navigation Co's Briquetting Plant

ALL the coal handling, screening and storage equipment of the Virginia Navigation Company's ideal briquetting plant at Norfolk, Va., was designed, fabricated and erected by us. The owners are justly proud of the installation—and so are we.

For, almost since the end of the Civil War, we have specialized in the design and production of coal handling and preparing equipment. All those years of study and experiment are now reflected in every piece of Link-Belt mining machinery.

This equipment includes elevators and conveyors of all kinds, shaking screens, picking tables, chutes, car dumps, storage systems, locomotive cranes, etc., as well as the design and fabrication of the structural steel of the tipple itself.

Write us about your proposed plant or improvements. No installation too small—none too large. Let our engineers help you. Ask for our Coal Book No. 333.
